
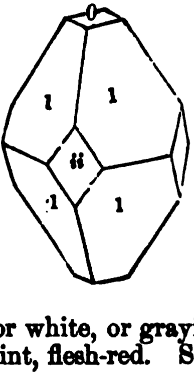
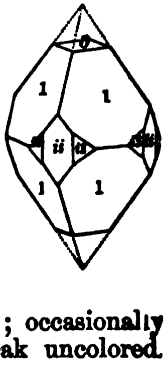
388



399



Transparent; rarely opaque. Brittle. Double refraction feeble; either positive or negative; sometimes a tesselated structure made apparent by polarized light.

Var.—1. *Ordinary.* Usually in crystals, which are remarkable for their pearly basal cleavage Form sometimes nearly cubic.

Haüy's *Mesotype épointée* was an Iceland variety; Fuchs and Gehlen in 1816 ascertained its identity with apophyllite. In tabular crystals from the Seisser-Alp Dauber found 1 ∧ 1 = 121° 7½′; in red from Andreasberg 120° 29′ 18″; in crystals from Poonah 119° 43′.

1. The name *Oxhaverite* was applied to a pale green crystal found in petrified wood at the Oxhaver Springs, near Husavick in Iceland. *Albin* of Werner (named from *albus*, *white*) is in small nearly cubic crystals, opaque white in color, from Aussig, Bohemia, partly decomposed. *Xylochlore*, from Sicily, is olive-green, and has G.=2·2904; it owes its color to the presence of a little iron.

2. *Tesselite*, from Faröe, is a cubical variety, exhibiting a tesselated structure in polarized light.

3. *Leucocyclite*, when plates parallel to the base are examined by means of polarized light, shows a black cross with rings that are alternately white and violet black, with compensation positive (whence the name, from λευκός, *white*, and κύκλος, *circle*), instead of the ordinary colored rings—a peculiarity observed in crystals from the Seisser-Alp, Andreasberg (part of those of this locality), Skye, Faröe, Iceland, Utö, and Poonah in India. Some crystals from Utö and Cziklowa, similarly examined, exhibit a black cross on a deep violet ground, with compensation negative. These different optical phenomena may be presented by contiguous plates of the same crystal; Descl.

Comp.—A silicate of lime and potash containing some fluorine. O. ratio for $\dot{R}$, $\ddot{Si}$, $\dot{H}$ mostly 1 : 3·75 : 2; for the analysis by Berzelius, 1 : 4 : 2; and for $\dot{Ca}$, $\dot{K}$, 8 : 1. Ratio usually taken at 1 : 4 : 2; which corresponds to $\dot{R}+2\ddot{Si}+2\dot{H}$; and if 1 $\dot{H}$ be basic, the formula may be $\dot{R}^2\ddot{Si}+\dot{H}\ddot{Si}$, or more specially $(\frac{1}{2}\dot{H}+\frac{1}{2}(\frac{1}{9}\dot{K}+\frac{8}{9}\dot{Ca}))^2\ddot{Si}+\dot{H}\ddot{Si}$=Silica 55·5, lime 23·0, potash 4·8, water 16·7=100. This makes it a Unisilicate, like other tetragonal silicates, with an opal-like (uncrystallizable ?) silicate as accessory. The ratio of the fluorine to the oxygen has not been ascertained.

Analyses: 1, 2, Berzelius (Afh., vi. 181); 3, Rammelsberg (2d Suppl., 16); 4, Stölting (B. H. Ztg., xx. 267); 5, Rammelsberg (Min. Ch., 505); 6, C. T. Jackson (This Min., 1850, 249); 7, E. L. Reakirt (Am. J. Sci, II. xvi. 84); 8, J. L. Smith (This Min., 304, 1854); 9, W. Beck (Verh. Min. St Pet., 1862, 92); 10, Haughton (Phil. Mag., IV. xxxii. 228):

	$\ddot{Si}$	$\dot{Ca}$	$\dot{K}$	$\dot{H}$	F
1. Utö	52·13	24·71	5·27	16·20	1·54=99·85 Berzelius.
2. Faröe, *Tesselite*	52·38	24·98	5·37	16·20	1·12=100·05 Berzelius.
3. Andreasberg	51·33	25·86	4·90	*und.*	1·18 Ramm.
4. " *rdh.*	51·73	25·02	5·10	15·73	?=97·58 Stölting.
5. Radauthal, G.=1·961	52·69	25·52	4·75	16·73	0·46 Ramm.
6. Michigan, G.=2·305	51·89	25·60	5·07	16·00	0·91=99·47 Jackson.
7. Nova Scotia	52·60	24·88	5·14	16·67	1·71=101 Reakirt.
8. L. Superior, G.=2·37	52·08	25·30	4·93	15·92	0·96=99·19 Smith.
9. Pyterlax, Finl. (½)	52·12	24·99	5·75	16·47	0·84=100·17 W. Beck.
10. Bombay	51·60	25·08	5·04	16·20	0·97, $\ddot{\bar{A}}l$ 0·24, $\dot{Mg}$ 0·08, $\dot{Na}$ 0·63=99·84 H.

Xylochlore afforded v. Waltershausen, as a mean of two analyses (l. c.), $\ddot{Si}$ 52·07, $\dot{Ca}$ 20·57, $\ddot{F}e$ 3·40, $\dot{Mg}$ 0·33, $\dot{Na}$ 0·55, $\dot{K}$ 3·77, $\ddot{\bar{A}}l$ 1·54, $\dot{H}$ and $\ddot{C}$ 17·14=99·37. The red color of the Andreasberg crystals is attributed by Suckow to fluorid of cobalt.

Pyr., etc.—In the closed tube exfoliates, whitens, and yields water, which reacts acid. In the open tube, when fused with salt of phosphorus, gives a fluorine reaction. B.B. exfoliates, colors the flame violet (potash), and fuses to a white vesicular enamel. F.=1·5 (v. Kobell). Decomposed by muriatic acid, with separation of slimy silica.

Obs.—Occurs commonly in amygdaloid and related rocks, with various zeolites; also occasionally in cavities in granite, gneiss, etc. Greenland, Iceland, the Faröe Islands, Poonah and Ahmednuggar in Hindostan, afford fine specimens of apophyllite in amygdaloid. At Andreasberg, in silver veins, traversing gray-wacke slate; at Orawicza, Csiklowa, and Szaszka in Transylvania, associated with wollastonite; in Fifeshire, with magnetic iron; at Utö in Sweden; at Puy de la Piquette in Auvergne, in a tertiary limestone, near intruded basaltic rocks; at Finbo, Utö, and Hällesta, Sweden; in the Tyrol, near Frombach; near Nertschinsk, Siberia; in Australia; the Valencian Mines, Mexico.

In America it has been found at Peter's Point and Partridge Island, in the Basin of Mines, Nova Scotia, both massive and crystallized, presenting white, reddish, and greenish colors, and associated with laumontite, thomsonite, and other minerals of trap rocks; also at Chute's cove, Cape d'Or, Isle Haute, Swan's Creek, and Cape Blomidon. Large crystals occur at Bergen Hill, N. J., associated with analcite, pectolite, stilbite, datolite, etc., some of them 3 inches across. It is also found at Gin Cove, near Perry, Maine, with prehnite and analcite in amygdaloid; at the Cliff mine, Lake Superior region (f. 399).

Apophyllite was so named by Haüy in allusion to its tendency to exfoliate under the blowpipe, from ἀπό and φύλλον, *a leaf*. Its whitish pearly aspect, resembling the eye of a fish after boiling, gave rise to the name *Ichthyophthalmite*, from ἰχθύς, *fish*, and ὀφθαλμός, *eye*.

The name *ichthyophthalmite* (or *ichthyophthalme*), given in 1800 by d'Andrada, has priority. But d'Andrada's description (l. c.) is bad in all respects, answering much better for pearly feldspar or adularia, even the specific gravity (2·491) being far out of the way; it affords some evidence that he may have drawn it from another mineral. It was therefore hardly a violation of the strictest rule of priority that Haüy, who had studied carefully the crystallization of the mineral before it was known to d'Andrada, should have named it anew. Neither justice to d'Andrada, nor the good of science, requires that the name *apophyllite* should now yield place to the earlier one. The earliest analyses were made in 1805 by V. Rose (Gehlen's J., v.), and Fourcroy & Vauquelin (Ann. du Mus., v.).

Alt.—Occurs altered to pectolite near Tiexno on Monte Baldo, along with unchanged crystals.

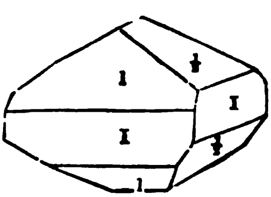
Artif.—Crystals have been obtained by Wöhler from heated waters, and he inferred that a temperature of 180° F. was necessary to the result. He stated that when heated in water to this temperature under a pressure of 10 to 12 atmospheres, it forms a solution which crystallizes on cooling. Pearly radiated crystals were formed by Becquerel through the action of a solution of silicate of potash on plates of sulphate of lime (gypsum). Daubrée has detected crystals of apophyllite in the Roman works at the hot springs of Plombières; they were covered in part with incrusting and stalactitic hyalite.

371. EDINGTONITE.

Haid., Brewster's Ed. J. Sci., iii. 316, 1825. Antiedrit *Breith.*, Char 164, 1832.

Tetragonal; hemihedral. $O \wedge 1\text{-}i = 145° \, 59'$; $a = 0{\cdot}67473$. Observed planes as in the annexed figure, together with another dome in the zone $\frac{1}{2}$, having the summit angle 144°. $O \wedge 1 = 136° \, 20\frac{1}{2}'$, $I \wedge 1 = 133° \, 39\frac{1}{2}'$, $I \wedge \frac{1}{2} = 115° \, 26$, $1 \wedge 1$, over summit, $= 92° \, 41'$, $\frac{1}{2} \wedge \frac{1}{2}$, ib., $= 129° \, 8'$. Cleavage: I perfect. Also massive.

390



H.=4–4·5. G.=2·71, Haid.; 2·694, Heddle. Lustre vitreous. White, grayish-white, pink. Streak uncolored. Translucent—opaque. Brittle.

Comp.—O. ratio for $\dot{R}$, $\ddot{\bar{R}}$, $\ddot{Si}$, $\dot{H} = 1:4:7:4$; whence, if half the water is basic, for bases, silica and water $7:7:2 = 1:1:\frac{2}{7}$; and the formula $(\frac{4}{7}(\frac{2}{3}\dot{H} + \frac{1}{3}\dot{Ba})^3 + \frac{3}{7}\ddot{\bar{Al}})^2\ddot{Si}^3 + 1\frac{4}{7}\dot{H}$. A new determination of the composition is needed. Analysis: F. Heddle (Phil. Mag., IV. ix. 179):

$\ddot{Si}$ 36·98 $\ddot{\bar{Al}}$ 22·63 $\dot{Ba}$ 26·84 Ca *tr.* $\dot{Na}$ *tr.* $\dot{H}$ 12·46=98·91.

Turner obtained, in an imperfect and incorrect analysis (Brewst. Ed. J. Sci., iii. 318), $\ddot{Si}$ 35·09, $\ddot{\bar{Al}}$ 27·69, $\dot{Ca}$ 12·68, $\dot{H}$ 13·32, loss 11·22 supposed to be some alkali.

Pyr., etc.—Yields water, and becomes white and opaque. B.B. at a high heat fuses to a colorless mass. Affords a jelly with muriatic acid.

Obs.—Edingtonite occurs in the Kilpatrick Hills, near Glasgow, Scotland, associated with harmotome, another baryta mineral, and also analcite, calcite, etc. One specimen obtained by Mr. Heddle weighed 2½ oz.

Glottalite of Thomson (Min., i. 328), from Port Glasgow, on the Clyde, Scotland, is described as occurring in white crystals that "seem to be regular octahedrons; at least 4-sided pyramids, the faces of which appear to be equilateral triangles, are visible; other crystals appear to be cubic." H.=3·5; G.=2·18; lustre vitreous. Thomson obtained (l. c.) $\ddot{Si}$ 37·01, $\ddot{\bar{Al}}$ 16·31, $\ddot{\bar{Fe}}$ 0·50, $\dot{Ca}$ 23·93, $\dot{H}$ 21·25=99·00. Heddle states (Phil. Mag., IV. ix. 181) that it is probably edingtonite mixed with harmotome, mentioning that Thomson's mineral came from the same locality with the edingtonite, and from the same dealer that furnished him with the edingtonito for his analysis.

372. GISMONDITE. Zeagonite *Gismondi*, Osserv. Min. di Roma, 1816, Tasch. Min., xi. 164 1817. Gismondin *Leonh.*, ib., 168. Gismondine. Abrazite *Breislak*, Instit. Geol., iii. 198. Aricite

Orthorhombic. $I \wedge I = 93° 41'$, $O \wedge 1\text{-}\bar{\imath} = 134° 35'$; $a : b : c = 1{\cdot}0664 : 1 : 1{\cdot}0146$. $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}$, top, $= 89° 10'$, $I \wedge 1\text{-}\breve{\imath} = 124° 42'$, v. Lang. Forms resembling square octahedrons, but made up of the planes I and $1\text{-}\bar{\imath}$; often clustered into mammillated forms with a drusy surface. Cleavage: I, rather perfect.

H.=4·5. G.=2·265. Colorless or white, bluish-white, grayish, reddish. Lustre splendent. Transparent to translucent. Optically biaxial; optic-axial plane parallel to axis *a*, and angle very large, v. Lang; but usually only confused appearances in polarized light, Descl.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\bar{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=1 : 3 : 4½ : 4½. Formula perhaps that of ekebergite *plus* the water. Analysis by Marignac (Ann. Ch. Phys., III. xiv. 41):

$\ddot{\mathrm{S}}\mathrm{i}$ 35·38 $\bar{\bar{\mathrm{A}}}\mathrm{l}$ 27·23 $\dot{\mathrm{C}}\mathrm{a}$ 13·12 $\dot{\mathrm{K}}$ 2·85 $\dot{\mathrm{H}}$ 21·10=100·18.

Pyr., etc.—At 100° C. yields one-third of its water, and becomes opaque. B.B. whitens, intumesces much, and melts to a milky glass. Easily dissolves in acids and gelatinizes.

Obs.—Occurs in the leucitophyr, a leucitic lava, of the region of Mt. Albano, south-east of Rome, at Capo di Bove, and elsewhere, associated with pyroxene, magnetite, mellilite, phillipsite, wollastonite, etc.; also, according to Kenngott, on the Gorner glacier, near Zermatt, in cavities in a coarse, granular, reddish-brown garnet-rock, with epidote, calcite, chlorite, and genthite; also in the Val di Noto, Sicily, according to Scacchi, in white mammillary concretions, fibrous within.

The name *Zeagonite* is from ζέω, *to cook*, and ἄγονος, *barren*, and was the first name of the species. Leonhard substituted the describer's name, which it has since held.

Von Kobell and Marignac have analyzed crystals from the locality at Capo di Bove with a result very different from the above; and it is supposed that the crystals taken for the analyses were a mixture of gismondite and phillipsite. The crystals were, however, received from the Italian mineralogist Medici-Spada. Credner examined a part of the same lot of crystals, and has described and figured them in the Jahrb. Min. 1847, p. 559; and the figures have the twin forms (cruciform to octahedral) and striæ of phillipsite. He describes others that are rounded octahedral, with rough edges without the striæ—the true gismondite, according to most authors—but adds that even-faced octahedrons graduate imperceptibly into the rough, and that all appear to be one species. He consequently makes all the crystals orthorhombic, and closely related to phillipsite. But v. Lang has shown that the crystals are not twins, and have the above angles (Phil. Mag., IV. xxviii. 505).

Von Kobell (in the Gel. Anz. München, 1839) described the crystals as tetragonal, mentioned the twins, and published the following analysis. He also places the species very near phillipsite, and in his Geschichte der Min. (p. 487) he even queries the identity of the two. Marignac also made the crystals tetragonal octahedrons, with the angles of basal edges 92° 30′, and of pyramidal 118° 31′. Analyses: 1, v. Kobell (l. c. and J. pr. Ch., xviii. 105); 2, Marignac (Ann. Ch. Phys., III. xiv. 41, 1845):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	42·60	25·50	7·50	6·80	17·66=100·06 Kobell.
2.	43 64	24·39	6·92	10·35	15·05=100·85 Marignac.

The O. ratio for the first is near 1 : 4 : 7½ : 5; for the second 1 : 3 : 6 : 3½. These analyses are sometimes placed under the name *zeagonite*, as if a third mineral existed at Capo di Bove distinct from the phillipsite and gismondite. But v. Kobell holds that his results give the true composition of gismondite. L. Gmelin, more than 40 years ago, made a chemical examination that led him to refer gismondite to phillipsite. Marignac regarded the mineral analyzed by him (anal. 2) as true phillipsite.

Certain pale bluish octahedral crystals from Vesuvius, affording, according to Phillips, the terminal angle 122° 58′, have been called *zeagonite*, which Hausmann refers to zircon (Handb., ii. 797).

373. CARPHOLITE. Karpholith *Wern.*, Letztes Min. Syst., 10, 43, 1817.

Orthorhombic. In radiated and stellated tufts, and groups of acicular crystals. Rhombic prisms of 111° 27′, and 68° 33′, Kenngott, with lateral edges truncated.

H.=5—5·5. G.=2·935, Breithaupt; 2·9365, Stromeyer. Lustre silky, glistening. Color pure straw-yellow to wax-yellow. Opaque. Very brittle.

Comp.—O. ratio for $\overline{\mathrm{R}}$, $\dddot{\mathrm{Si}}$ $\dot{\mathrm{H}}$=1 : 1 : ⅓, if the bases are all sesquioxyd, as made by v. Hauer; giving the formula $(\overline{\mathrm{Al}}, \overline{\mathrm{Mn}}, \overline{\mathrm{Fe}})^2 \dddot{\mathrm{Si}}^3+3\dot{\mathrm{H}}$. Analyses: 1, Stromeyer (Untersuch., 410); 2, Steinmann (Schw. J., xxv. 418); 3, v. Hauer:

	$\dddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Mn}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$	HF
1.	36·15	28·67	19·16	——	2·29	0·27	10·78	1·47=98·79 Stromeyer.
2.	37·58	26·47	18·33	6·27	——	——	11·36	——=99·96 Steinmann.
3.	36 15	19·74	20·76	9·87	——	1·83	10·19	F 1·74=100·28 Hauer.

Pyr., etc.—In the closed tube gives water, which reacts acid and attacks the glass (fluorine). B.B. swells up and fuses at 3·5 to a brown glass. With the fluxes gives reactions for manganese and iron. Not decomposed by muriatic acid. Decomposed on fusion with alkaline carbonates.

Obs.—Occurs in minute divergent tufts, disposed on granite, along with fluor and quartz, in the tin mines of Schlackenwald. It was named by Werner in allusion to its color, from κάρφος, *straw*. Von Kobell suggests that the mineral is altered marceline (Geschichte Min., 677).

III. SUBSILICATES.

374. ALLOPHANE. Allophan *Stromeyer*, Gel. Anz. Gött., 1251, 1816. Riemannit *Breith.*, Hoffm. Min., iv. b, 182, 1817. Elhuyarit *Sack*, Schw. J., lxv. 110, 1832 (announced, not named), Jahrb. Min., 28, 1834 (mentioned, not described).

Amorphous. In incrustations, usually thin, with a mammillary surface, and hyalite-like; sometimes stalactitic. Occasionally almost pulverulent.

H.=3. G.=1·85—1·89. Lustre vitreous to subresinous; bright and waxy internally. Color pale sky-blue, sometimes greenish to deep green, brown, yellow, or colorless. Streak uncolored. Translucent. Fracture imperfectly conchoidal and shining, to earthy. Very brittle.

Comp.—O. ratio for $\overline{\mathrm{Al}}$, $\dddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, mostly=3 : 2 : 6 (or 5); $\overline{\mathrm{Al}}\,\dddot{\mathrm{Si}}+6\dot{\mathrm{H}}$ or $\overline{\mathrm{Al}}\,\dddot{\mathrm{Si}}+5\dot{\mathrm{H}}$.

Analyses: 1, Stromeyer (Unters., 308); 2, Walchner (Schw. J., xlix. 154); 3, Guillemin (Ann. Ch. Phys., xlii. 260); 4, Bunsen (Pogg., xxxi. 53); 5, Berthior (Ann. d. M., III. ix. 498); 6–9, A. B. Northcote (Phil. Mag., IV. xiii. 388); 10, Silliman, Jr. (Am. J. Sci., II. vii. 417); 11, C. T. Jackson (ib., xix. 119):

	$\dddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
1. Gräfenthal	21·92	32·20	0·73	41·30, $\dot{\mathrm{Cu}}\ddot{\mathrm{C}}$ 3·06, gyps. 0·52, $\overline{\mathrm{Fe}}^2\dot{\mathrm{H}}^3$ 0·27=99·88 S

9. " *ruby-red*	17·05	32·88	1·34	40·31, $\overline{\mathrm{Fe}}$ 6 59, $\ddot{\mathrm{C}}$ 1·82=99 99 Northcote.
10. Richmond, Mass.	22·65	38·77	——	35·24, $\dot{\mathrm{Mg}}$ 2·83=99·49 Silliman.
11. Tennessee	19·8	41·0	0·5	37·7, $\dot{\mathrm{Mg}}$ 0·2=99·2 C. T. Jackson.

The coloring matter of the blue variety is due to traces of chrysocolla, the green to malachite, and that of the yellowish and brown to iron. Allophane occurs at Richmond, Mass., mixed intimately with part of the gibbsite of that locality (Silliman).

Pyr., etc.—Yields much water in the closed tube. B.B. crumbles, but is infusible. Gives a blue color with cobalt solution. Gelatinizes with muriatic acid.

Obs.—Allophane is regarded as a result of the decomposition of some aluminous silicate (feldspar, etc.); and it often occurs incrusting fissures or cavities in mines, especially those of copper and limonite, and even in beds of coal. It lines cavities in a kind of marl at Gräfenthal, near Saalfeld in Thuringia, where it was first observed, in 1809, by Riemann, and hence has been called *riemannite*. Found also at Schneeberg in Saxony; at Gersbach in the Schwarzwald; Petrow in Moravia, in a bed of limonite; Chotina in Bohemia, at a copper mine in alum slate; at Friesdorf, near Bonn, in lignite (the *elhuyarite*, of a brownish or honey-yellow color, with G.=1·6); Visé in Belgium, in the carboniferous limestone; at the Chessy copper mine, near Lyons. France; in the chalk of Beauvais, France, presenting a honey-yellow color; at New Charlton, near Woolwich, in Kent, England, in old chalk-pits, of amber-yellow, ruby-red. and nearly opaque white colors. In the United States it occurs in a mine of limonite, with gibbsite, at Richmond, Mass., forming a hyaline crust, scaly or compact in structure, and brittle; at the Bristol Copper Mine, Ct.; at Morgantown, Berks Co., Pa.; at the Friedensville zinc mines, Pa.; in the copper mine of Polk Co., Tenn.

Named from ἄλλος, *other*, and φαίνω, *to appear*, in allusion to its change of appearance under the blowpipe.

A yellowish-white earthy mineral from Kornwestheim, between Stuttgart and Ludwidsburg, with G.=1·794 and 2·098, consists of allophane and aluminite in combination, and has been called *Kiesel-aluminite* (*Siliceous aluminite*) by Groningen and Oppel. In one of their analyses they obtained (Jahresb. 1852, 892, from Würtemb. Nat. Jahreshefte, 1851, 189) $\ddot{\mathrm{Si}}$ 13·06, $\dddot{\mathrm{S}}$ 5·04, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 42·59, ign. 39·32=100·01.

A. Carolathine *F. L. Sonnenschein* (ZS. G. Ges., v. 223, and J. pr. Ch., lx. 268, 1853). Amorphous, with a mammillary surface, and approaching allophane in the ratio of $\ddot{\mathrm{Si}}$ to $\dddot{\bar{\mathrm{A}}}\mathrm{l}$, but contains less water. H.=2·5; G.=1·515; color honey- to wine-yellow; subtranslucent.

Analysis by Sonnenschein gave:

$\ddot{\mathrm{Si}}$ 29·62 $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 47·25 $\dot{\mathrm{H}}$ 15·10 C 1·33 H 0·74 O 5·96=100.

Heated it affords water, which is neutral in its reactions; at a higher temperature decrepitates, the color darkens, and a black shining mass is obtained. B.B. ignites without flame, owing to the organic ingredients present.

From the coal-bed of the Königin-Louisa Mine, at Zabrze, in Upper Silesia.

375. COLLYRITE. Das man dort Salpeter nannte (fr. Schemnitz) *Freiesleben*, Lempe's Mag., x. 99, 1793. Naturliche Alaunerde (fr. Schemnitz) *v. Fichtel*, Min., 170, 1794; *Klapr.*, Beitr., i. 257, 1795. Kollyrit *Karst.*, Tab., 30, 78, 1800

A clay-like mineral, white, with a glimmering lustre, greasy feel, and adhering to the tongue. G.=2—2·15. H.=1—2.

Comp.—$\dddot{\bar{\mathrm{A}}}\mathrm{l}^2\,\ddot{\mathrm{Si}}+9\,\dot{\mathrm{H}}$; or 1 of Allophane+1 of Gibbsite=$[\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\ddot{\mathrm{Si}}+6\,\dot{\mathrm{H}}]+[\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dot{\mathrm{H}}^3]$=Silica 14·14, alumina 48·02, water 37·84. Analyses: 1, Klaproth (Beitr., i. 257); 2, Berthier (Ann. d. M., ii. 476); 3, Kersten (Schw. J., lxi. 24); 4, J. H. and G. Gladstone (Phil. Mag., IV. xxiii. 461, 1862):

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{H}}$
1. Schemnitz	14·0	45·0	42·0=101 Klaproth.
2. Ezquerra	15·0	44·5	40·5=100 Berthier.
3. Saxony	23·3	42·8	34·7=100·8 Kersten.
4. Hove	14·49	47·44	36·39, $\dot{\mathrm{C}}\mathrm{a}$ 0·89, $\ddot{\mathrm{C}}$ 0·79=100 Gladstone.

In other specimens Gladstone (l. c.) obtained from 8 to 3 p. c. of silica, indicating a varying proportion of hydrate of alumina.

Pyr., etc.—Yields water. B.B. infusible. Gives a blue color when heated with cobalt solution. Gelatinizes with nitric acid. Does not fall to pieces in water, or increase in weight.

Obs.—From Ezquerra in the Pyrenees; near Schemnitz, Hungary; near Wessenfels, Saxony; at Hove, near Brighton, England, in fissures in the upper chalk, of a pure white color and very soft.

The name *collyrium* (κολλύριον) was applied by the Greeks to the "Samian earth;" Karsten adopted it because the description of this earth by Dioscorides answers well for the above mineral

376A. DILLNITE Haid. (Pogg., lxxviii. 577, 1849) is a related substance. Earthy, with H.=1·8–2; G.=2·574–2·835. Analyses: Hutzelmann and Karafiat (Pogg., lxxviii. 576):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$
1.	22·40	56·40	0·44	*tr.*	21·13, $\dot{\mathrm{F}}\mathrm{e}$, $\dot{\mathrm{M}}\mathrm{n}$, alk. *tr.*=100·87 Hutzelmann.
2.	23·53	53·00	1·76	0·88	20·05=99·22 Karafiat.

The analyses correspond to the formula $\ddot{\bar{\mathrm{A}}}\mathrm{l}^4\,\ddot{\mathrm{S}}\mathrm{i}^3+9\,\dot{\mathrm{H}}$=Silica 24·39, alumina 54·23, $\dot{\mathrm{H}}$ 21·38. The dillnite is the gangue of the diaspore of Schemnitz, at a place called Dilln. Dr. J. L. Smith obtained a very different result for a similar material from the same Schemnitz locality, as given under PHOLERITE (q. v.); and it is probable that dillnite is a mixture of diaspore and kaolinite or pholerite.

376. SCHRÖTTERITE.

Opalin-Allophan *Schrötter*, Baumg. Ztg., iv. 145, 1837. Schrötterit *Glocker*, Grundr., 586, 1839. Opal Allophane.

Resembles allophane; sometimes like gum in appearance.

H.=3–3·5. G.=1·95–2·05. Color pale emerald- to leek-green, greenish-white, yellowish, or at times spotted with brown. Translucent to nearly transparent.

Comp.—O. ratio for $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=4:1:5; $\ddot{\bar{\mathrm{A}}}\mathrm{l}^8\,\ddot{\mathrm{S}}\mathrm{i}^3+30\,\dot{\mathrm{H}}$; equivalent to $3\,[\ddot{\bar{\mathrm{A}}}\mathrm{l}\,\ddot{\mathrm{S}}\mathrm{i}+5\,\dot{\mathrm{H}}]+5\,[\ddot{\bar{\mathrm{A}}}\mathrm{l}\,\dot{\mathrm{H}}^3]$, or 3 of allophane and 5 of gibbsite. Analyses: 1, 2, Schrötter (J. pr. Ch., xi. 380); 3, J. W. Mallet (Am. J. Sci., II. xxvi. 79):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\ddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{H}}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{H}}$
1. Styria	11·95	46·30	2·95	36·20	1·30	0·25	0·78=99·73 Schrötter.
2. "	11·93	46·28	2·66	35·50	1·03	0·25	0·48=98·14 Schrötter.
3. Alabama	(½) 10·53	46·48	—	41·09, $\dot{\mathrm{Z}}\mathrm{n}$ 0·77, $\dot{\mathrm{F}}\mathrm{e}$, $\dot{\mathrm{M}}\mathrm{g}$ *tr.*, $\ddot{\mathrm{S}}$ 0·80=99·67 Mallet.			

Pyr., etc.—B.B. acts like allophane, but burns white. Decomposed by acids.

Obs.—From Dollinger mountain, near Freienstein, in Styria, in nests between clay-slate and granular limestone; in Cornwall; at the Falls of Little River, on the Sand Mtn., Cherokee Co., Alabama, as an incrustation over half an inch thick and partly stalactitic, resembling gum arabic when broken, having H.=3·5, and G.=1·974.

376A. SCARBROITE *Vernon* (Phil. Mag., II. v. 178, 1829) is a white clayey substance, allied to schrötterite in composition. It is without lustre, highly adhesive to moist surfaces, and may be polished by the nail; H.=2·0; G.=1·485? Composition, according to an imperfect analysis by Vernon (l. c.), $\ddot{\mathrm{S}}\mathrm{i}$ 10·50, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 42·50, $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·25, $\dot{\mathrm{H}}$ 46·75. In a second, equally imperfect, he obtained $\ddot{\mathrm{S}}\mathrm{i}$ 7·90, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 42·75, $\dot{\mathrm{H}}$ 48·55, $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·80=100. Does not fall to pieces in water, but increases in weight. It fills the veinings of a sandstone, which is much marked with oxyd of iron, or of its septaria, on the coast of Scarborough, Yorkshire, England.

II. ZEOLITE SECTION.

ARRANGEMENT OF THE SPECIES.

I. MESOTYPE GROUP. Anisometric; angle *I* ∧ *I* near 90°; cleavage parallel to *I*. Crystallizations often acicular, or long fibrous and radiating; thomsonite sometimes in short nearly rectangular forms, with flat summits, and sometimes foliated, but with a less pearly and more glassy surface than in stilbite.

	$\dot{\mathrm{R}}$	$\ddot{\bar{\mathrm{R}}}$	$\ddot{\mathrm{S}}\mathrm{i}$	$\dot{\mathrm{H}}$	$\dot{\mathrm{R}}\ddot{\bar{\mathrm{R}}}$	$\ddot{\mathrm{S}}\mathrm{i}$	$\dot{\mathrm{H}}$	
377. THOMSONITE	1	3	4	2½	1	1	⅝	$(\frac{2}{3}\dot{\mathrm{C}}\mathrm{a}+\frac{1}{3}\dot{\mathrm{N}}\mathrm{a})$, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, $2\,\ddot{\mathrm{S}}\mathrm{i}$, $2\frac{1}{2}\,\dot{\mathrm{H}}$
378. NATROLITE	1	3	6	2	1	1½	½ .½)	$\dot{\mathrm{N}}\mathrm{a}$, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, $3\,\ddot{\mathrm{S}}\mathrm{i}$, $2\,\dot{\mathrm{H}}$

	$\dot{\rm R}$	$\dddot{\overline{\rm R}}$	$\ddot{\rm Si}$	$\dot{\rm H}$	$\dot{\rm R}\dddot{\overline{\rm R}}$	$\ddot{\rm Si}$	$\dot{\rm H}$	
379. SCOLECITE	1	3	6	3	1	1½	¾ (⅔)	$\dot{\rm Ca}, \dddot{\overline{\rm Al}}, 3\ddot{\rm Si}, 3\dot{\rm H}$
380. ELLAGITE	1	3	6	3	1	1½	¾ (⅔)	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}\dot{\rm Fe}), \dddot{\overline{\rm Al}}, 3\ddot{\rm Si}, 3\dot{\rm H}$
381. MESOLITE	1	3	6	3	1	1½	¾ (⅔)	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}\dot{\rm Na}), \dddot{\overline{\rm Al}}, 3\ddot{\rm Si}, 3\dot{\rm H}$

II. **LEVYNITE GROUP.** Hexagonal. $R \wedge R=106°$ nearly.

382. LEVYNITE	1	3	6	4	1	1½	1 (½)	$(\dot{\rm Ca}, \dot{\rm Na}, \dot{\rm K}), \dddot{\overline{\rm Al}}, 3\ddot{\rm Si}, 4\dot{\rm H}$

III. **ANALCITE GROUP.** Isometric, or else orthorhombic with $I \wedge I=120°$. O. ratio for $\dot{\rm R}, \dddot{\overline{\rm R}}, \ddot{\rm Si}=1:3:8$, or $1:3:9$. Never fibrous or acicular.

383. ANALCITE	1	3	8	2	1	2	½	$\dot{\rm Na}, \dddot{\overline{\rm Al}}, 4\ddot{\rm Si}, 2\dot{\rm H}$
384. EUDNOPHITE	1	3	8	2	1	2	½	$\dot{\rm Na}, \dddot{\overline{\rm Al}}, 4\ddot{\rm Si}, 2\dot{\rm H}$
385. FAUJASITE	1	3	9	9	1	2¼	2¼	$(\frac{1}{2}\dot{\rm Ca}+\frac{1}{2}\dot{\rm Na}), \dddot{\overline{\rm Al}}, 4\frac{1}{2}\ddot{\rm Si}, 9\dot{\rm H}$

IV. **CHABAZITE GROUP.** Hexagonal, or else orthorhombic with $I \wedge I=120°$. O. ratio for $\dot{\rm R}, \dddot{\overline{\rm R}}, \ddot{\rm Si}=1:3:8$, or $1:3:9$. Never fibrous or acicular. Not pearly foliated.

386. CHABAZITE	1	3	8	6	1	2	1½	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}(\dot{\rm Na}, \dot{\rm K})), \dddot{\overline{\rm Al}}, 4\ddot{\rm Si}, 6\dot{\rm H}$
387. GMELINITE	1	3	8	6	1	2	1½	$(\frac{1}{3}\dot{\rm Ca}+\frac{2}{3}(\dot{\rm Na}, \dot{\rm K})), \dddot{\overline{\rm Al}}, 4\ddot{\rm Si}, 6\dot{\rm H}$
388. HERSCHELITE	1	3	8	5	1	2	1¼	$(\frac{2}{3}\dot{\rm Na}+\frac{1}{3}\dot{\rm K}), \dddot{\overline{\rm Al}}, 4\ddot{\rm Si}, 5\dot{\rm H}$

V. **PHILLIPSITE GROUP.** Orthorhombic; $I \wedge I$ near 90°. Often in cruciform twins; never fibrous or acicular. Not pearly foliated.

389. PHILLIPSITE	1	3	8	5	1	2	1¼	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}\dot{\rm K}), \dddot{\overline{\rm Al}}, 4\ddot{\rm Si}, 5\dot{\rm H}$

VI. **HARMOTOME GROUP.** Orthorhombic; $I \wedge I=124°-125°$. Often in cruciform twins; never fibrous or acicular. Lustre vitreous.

390. HARMOTOME	1	3	10	5	1	2½	1¼ (⅙)	$\dot{\rm Ba}, \dddot{\overline{\rm Al}}, 5\ddot{\rm Si}, 5\dot{\rm H}$

VII. **HYPOSTILBITE GROUP.** Like the mesotypes in acicular and fibrous crystallizations and absence of pearly cleavage. O. ratio for $\dot{\rm R}, \dddot{\overline{\rm R}}, \ddot{\rm Si}=1:3:9$.

391. HYPOSTILBITE	1	3	9	6	1	2¼	1½ (⅙)	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}\dot{\rm Na}), \dddot{\overline{\rm Al}}, 4\frac{1}{2}\ddot{\rm Si}+6\dot{\rm H}$

VIII. **STILBITE GROUP.** Orthorhombic or monoclinic, with an easy pearly diagonal or basal cleavage. O. ratio for $\dot{\rm R}, \dddot{\overline{\rm R}}, \ddot{\rm Si}=1:3:12$.

392. STILBITE	1	3	12	6	1	3	1½ (⅓)	$\dot{\rm Ca}, \dddot{\overline{\rm Al}}, 6\ddot{\rm Si}, 6\dot{\rm H}$
393. EPISTILBITE	1	3	12	5	1	3	1¼ (⅜)	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}\dot{\rm Na}), \dddot{\overline{\rm Al}}, 6\ddot{\rm Si}, 5\dot{\rm H}$
394. HEULANDITE	1	3	12	5	1	3	1¼ (⅜)	$\dot{\rm Ca}, \dddot{\overline{\rm Al}}, 6\ddot{\rm Si}, 5\dot{\rm H}$
395. BREWSTERITE	1	3	12	5	1	3	1¼ (⅜)	$(\frac{2}{3}\dot{\rm Sr}+\frac{1}{3}\dot{\rm Ba}), \dddot{\overline{\rm Al}}, 6\ddot{\rm Si}, 5\dot{\rm H}$
396. MORDENITE	1	3	18	6	1	4½	1½	$(\frac{2}{3}\dot{\rm Ca}+\frac{1}{3}\dot{\rm Na}), \dddot{\overline{\rm Al}}, 9\ddot{\rm Si}. 6\dot{\rm H}$

Appendix.—397. SLOANITE. 398. SASPACHITE.

In the preceding table the constituents of the species are stated without the arrangement of them into formulas. The resemblance to the Feldspar group in oxygen ratio seems, at first thought, to imply resemblance at least in scheme of composition. But it has been observed (p. 394) that instead of unity of crystalline form and physical characters, as in the Feldspar group, there is the utmost diversity. A relation between the proportion of silica and alkali holds through the feldspars; but none exists, or could be rightly looked for, among the varied groups here brought together under the name of zeolites. The water present has produced the wide divergence from the feldspars; and it is therefore probable that this water is in part, at least, basic. This being so, they may pertain to the two divisions of Unisilicates and Bisilicates. In the following table they are arranged under these heads, and formulas added to correspond with this reference of them.

The species of the Mesotype and Levynite groups are made Unisilicates, because they have not silica enough for the bisilicate type. Thomsonite has the O. ratio for the bases and silica $=1+3:4=1:1$, or that of a true Unisilicate; and natrolite, if the water be basic, is also unisilicate. Further, the close isomorphism of the several species of the Mesotype group renders it probable that they are similar chemically, and therefore all unisilicate.

The species of the remaining groups have silica enough for Bisilicates, and are so arranged in the following table. Yet those of the groups 3 to 5 have water enough for Unisilicates, if this water be mainly basic. Thus chabazite and gmelinite have a unisilicate ratio, if two-thirds of the water is basic; and herschelite and phillipsite, if four-fifths. But the facility with which part of the water in these species escapes is evidence that a considerable part of it, at least, is not basic. Chabazite loses over 7 p. c. of water, or more than a third, by simple exposure to dry air. For other similar facts, see under the species beyond. It is, therefore, not at all probable that enough water is basic to make the species unisilicate. In the preceding table, the fraction written after the column of $\dot{\mathrm{H}}$ indicates the proportion of water which is made basic in the formulas which here follow:

1. UNISILICATE.

1.	**Thomsonite**	$(\frac{1}{4}(\frac{2}{3}\dot{\mathrm{Ca}}+\frac{1}{3}\dot{\mathrm{Na}})^3+\frac{3}{4}\ddot{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3+3\frac{3}{4}\dot{\mathrm{H}}$	$\mathrm{Si}\vert\Theta_4\vert(\frac{1}{4}(\frac{2}{3}\Theta\mathrm{a}+\frac{1}{3}\mathrm{Na}_2)+\frac{3}{4}\beta\mathrm{Al})_2+1\frac{1}{4}\mathrm{aq}$
	Natrolite	$(\frac{1}{2}(\frac{2}{3}\dot{\mathrm{H}}+\frac{1}{3}\dot{\mathrm{Na}})^3+\frac{1}{2}\ddot{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3$	$\mathrm{Si}\vert\Theta_4\vert(\frac{1}{2}(\frac{2}{3}\mathrm{H}_2+\frac{1}{3}\mathrm{Na}_2)+\frac{1}{2}\beta\mathrm{Al})_2$
	Scolecite	$(\frac{1}{2}(\frac{2}{3}\dot{\mathrm{H}}+\frac{1}{3}\dot{\mathrm{Ca}})^3+\frac{1}{2}\ddot{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3+\dot{\mathrm{H}}$	$\mathrm{Si}\vert\Theta_4\vert(\frac{1}{2}(\frac{2}{3}\mathrm{H}_2+\frac{1}{3}\Theta\mathrm{a})+\frac{1}{2}\beta\mathrm{Al})_2+\frac{1}{3}\mathrm{aq}$
	Mesolite	$(\frac{1}{2}(\frac{2}{3}\dot{\mathrm{H}}+\frac{2}{9}\dot{\mathrm{Ca}}+\frac{1}{9}\dot{\mathrm{Na}})^3+\frac{1}{2}\ddot{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3+\dot{\mathrm{H}}$	$\mathrm{Si}\vert\Theta_4\vert(\frac{1}{2}(\frac{2}{3}\mathrm{H}_2+\frac{1}{3}(\Theta\mathrm{a},\mathrm{Na}_2))+\frac{1}{2}\beta\mathrm{Al})_2+\frac{1}{3}\mathrm{aq}$
	Ellagite	$(\frac{1}{2}(\frac{2}{3}\dot{\mathrm{H}}+\frac{2}{9}\dot{\mathrm{Ca}}+\frac{1}{9}\dot{\mathrm{Fe}})^3+\frac{1}{2}\ddot{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3+\dot{\mathrm{H}}$	$\mathrm{Si}\vert\Theta_4\vert(\frac{1}{2}(\frac{2}{3}\mathrm{H}_2+\frac{1}{3}\mathrm{R})+\frac{1}{2}\beta\mathrm{Al})_2+\frac{1}{3}\mathrm{aq}$
2.	**Levynite**	$(\frac{1}{2}(\frac{2}{3}\dot{\mathrm{H}}+\frac{1}{3}(\dot{\mathrm{Ca}},\dot{\mathrm{Na}},\dot{\mathrm{K}}))^3+\frac{1}{2}\ddot{\mathrm{Al}})^2\ddot{\mathrm{Si}}^3+2\dot{\mathrm{H}}$	$\mathrm{Si}\vert\Theta_4\vert(\frac{1}{2}(\frac{2}{3}\mathrm{H}_2+\frac{1}{3}(\mathrm{R}_2,\mathrm{R}))+\frac{1}{2}\beta\mathrm{Al})_2+\frac{2}{3}\mathrm{aq}$

2. BISILICATE.

3.	**Analcite**	$(\frac{1}{4}\dot{\mathrm{Na}}^3+\frac{3}{4}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+1\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{4}\mathrm{Na}_2+\frac{3}{4}\beta\mathrm{Al})+\frac{1}{2}\mathrm{aq}$
	Eudnophite	$(\frac{1}{4}\dot{\mathrm{Na}}^3+\frac{3}{4}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+1\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{4}\mathrm{Na}_2+\frac{3}{4}\beta\mathrm{Al})+\frac{1}{2}\mathrm{aq}$
	Faujasite	$(\frac{1}{3}\dot{\mathrm{H}}+\frac{1}{6}(\dot{\mathrm{Ca}},\dot{\mathrm{Na}}))^3+\frac{1}{2}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+n\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{3}\mathrm{H}_2+\frac{1}{6}(\Theta\mathrm{a},\mathrm{Na}_2))+\frac{1}{2}\mathrm{Al})+n\,\mathrm{aq}$
4.	**Chabazite**	$(\frac{1}{4}(\frac{5}{6}\dot{\mathrm{Ca}}+\frac{1}{6}\dot{\mathrm{Na}})^3+\frac{3}{4}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+4\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{4}(\Theta\mathrm{a},\mathrm{Na}_2)+\frac{3}{4}\beta\mathrm{Al})+1\frac{1}{2}\mathrm{aq}$
	Gmelinite	$(\frac{1}{4}(\frac{1}{3}\dot{\mathrm{Ca}}+\frac{2}{3}\dot{\mathrm{Na}})^3+\frac{3}{4}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+4\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{4}(\frac{1}{3}\Theta\mathrm{a}+\frac{2}{3}\mathrm{Na}_2)+\frac{3}{4}\beta\mathrm{Al})+1\frac{1}{2}\mathrm{aq}$
	Herschelite	$(\frac{1}{4}(\frac{3}{4}\dot{\mathrm{Na}}+\frac{1}{4}\dot{\mathrm{K}})^3+\frac{3}{4}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+3\frac{3}{4}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{4}(\frac{3}{4}\mathrm{Na}_2+\frac{1}{4}\mathrm{K}_2)+\frac{3}{4}\beta\mathrm{Al})+1\frac{1}{4}\mathrm{aq}$
5.	**Phillipsite**	$(\frac{1}{4}(\frac{2}{3}\dot{\mathrm{Ca}}+\frac{1}{3}\dot{\mathrm{K}})^3+\frac{3}{4}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+3\frac{3}{4}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{4}(\frac{2}{3}\Theta\mathrm{a}+\frac{1}{3}\mathrm{K}_2)+\frac{3}{4}\ \mathrm{Al})+1\frac{1}{4}\dot{\mathrm{H}}$
6.	**Harmotome**	$(\frac{2}{5}(\frac{1}{2}\dot{\mathrm{H}}+\frac{1}{2}\dot{\mathrm{Ba}})^3+\frac{3}{5}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+2\frac{2}{5}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{2}{5}(\frac{1}{2}\mathrm{H}_2+\frac{1}{2}\mathrm{Ba})+\frac{3}{5}\beta\mathrm{Al})+\frac{4}{5}\mathrm{aq}$
7.	**Hypostilbite**	$(\frac{1}{3}(\frac{1}{3}\dot{\mathrm{H}}+\frac{2}{3}(\dot{\mathrm{Ca}},\dot{\mathrm{Na}}))^3+\frac{2}{3}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+3\frac{2}{3}\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{3}(\frac{1}{3}\mathrm{H}_2+\frac{2}{3}(\Theta\mathrm{a},\mathrm{Na}_2))+\frac{2}{3}\beta\mathrm{Al})+1\frac{2}{9}\mathrm{aq}$
8.	**Stilbite**	$(\frac{1}{2}(\frac{2}{3}\dot{\mathrm{H}}+\frac{1}{3}\dot{\mathrm{Ca}})^3+\frac{1}{2}\ddot{\mathrm{Al}})\ddot{\mathrm{Si}}^3+2\dot{\mathrm{H}}$	$\mathrm{Si}\Theta\vert\Theta_2\vert(\frac{1}{2}(\frac{2}{3}\mathrm{H}_2+\frac{1}{3}\Theta\mathrm{a})+\frac{1}{2}\beta\mathrm{Al})+\frac{2}{3}\mathrm{aq}$

Epistilbite	$(\frac{1}{4}(\frac{1}{3}\dot{H}+\frac{2}{3}(\dot{C}a,\dot{N}a))^3+\frac{3}{4}\dddot{A}l)\ddot{S}i^3+1\frac{1}{4}\dot{H}$	$Si\,\Theta\,\|\,\Theta_2\,\|\,(\frac{1}{4}(\frac{1}{3}H_2+\frac{2}{3}R, R_2)+\frac{3}{4}\beta Al)+\frac{5}{4}aq$
Heulandite	$(\frac{1}{4}(\frac{1}{3}\dot{H}+\frac{2}{3}\dot{C}a)^3+\frac{3}{4}\dddot{A}l)\ddot{S}i^3+1\frac{1}{4}\dot{H}$	$Si\,\Theta\,\|\,\Theta_2\,\|\,(\frac{1}{4}(\frac{1}{3}H_2+\frac{2}{3}\Theta a)+\frac{3}{4}\beta Al)-\frac{5}{4}aq$
Brewsterite	$(\frac{1}{4}(\frac{1}{3}\dot{H}+\frac{2}{3}(\dot{B}a,\dot{S}r))^3+\frac{3}{4}\dddot{A}l)\ddot{S}i^3+1\frac{1}{4}\dot{H}$	$Si\,\Theta\,\|\,\Theta_2\,\|\,(\frac{1}{4}(\frac{1}{3}H_2+\frac{2}{3}(Ba, Sr))+\frac{3}{4}\beta Al)+\frac{5}{4}aq$
9. Mordenite	$(\frac{1}{4}(\frac{5}{6}\dot{H}+\frac{1}{6}(\dot{C}a,\dot{N}a))^3+\frac{3}{4}\dddot{A}l)\ddot{S}i^3+\frac{3}{4}\dot{H}$	$Si\,\Theta\,\|\,\Theta_2\,\|\,(\frac{1}{4}(\frac{5}{6}H_2+\frac{1}{6}(\Theta a, Na_2))+\frac{3}{4}\beta Al)+\frac{3}{4}aq$

The term zeolite was first used by Cronstedt in 1756 (Transactions of the Swedish Academy, vol. xviii.), for certain minerals that fused with much intumescence; the word being derived from ζέω, *to boil*, and λίθος, *stone*. Before the close of the century five subdivisions had been recognized by Werner and the mineralogists of his school: (1) *Mehlzeolith* (mealy zeolite); (2) *Fasriger zeolith* or *Faserzeolith* (fibrous zeolite); these two corresponding to the more modern mesotype (or natrolite, scolecite, mesolite, and thomsonite); (3) *Strahliger zeolith* or *Strahlzeolith* (radiated zeolite), now stilbite; (4) *Blättriger zeolith* or *Blätterzeolith* (foliated zeolite), now heulandite and apophyllite; (5) *Würfelzeolith* (cubic zeolite), now chabazite and analcite. Moreover, *Kreuzstein*, later called harmotome, and *Prehnite* were regarded as distinct species; and so also *Lapis Lazuli*, which had been ranked with the zeolites by Wallerius.

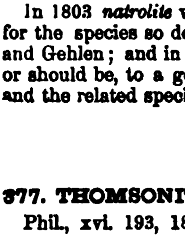
In 1801 Haüy gave the name of *Mesotype*, or *Zeolite* proper, to the varieties included under the first two of the above subdivisions, together with apophyllite; and took a second backward step, which he never retraced, in uniting those of the third and fourth in one species under the name of *Stilbite*. At the same time he rightly removed *Analcime* from the old *Cubic zeolite*.

In 1803 *natrolite* was separated from mesotype by Klaproth, and hence his name should stand for the species so designated. In 1813 *Scolecite*, and in 1816 *Mesolite*, were separated by Fuchs and Gehlen; and in 1820 *Thomsonite* by Brooke. Haüy's name mesotype is at present restricted, or should be, to a generic use to include the group of zeolites, viz., natrolite, scolecite, mesolite, and the related species.

377. THOMSONITE. Mesotype pt. *H.*, Tr., 1801. Thomsonite (fr. Scotland) *Brooke*, Ann. Phil., xvi. 193, 1820. Comptonite (fr. Somma) *Brewster*, Ed. Phil. J., iv. 131, 1821. Mesole *Berz.*, Ed. Phil. J., vii. 6, 1822. Triploklas *Breith.*, Char., 1832. Chalilite *T. Thomson*, Min., i. 324, 1836. Scoulerite *R. D. Thomson*, Phil. Mag., III. xvii. 408, 1840. Ozarkite (fr. Arkansas) *Shep.*, Am. J. Sci., II. ii. 251, 1846. Karphostilbit *v. Walt.*, Vulk. Gest., 272, 1853. Faröelite (=Mesole) *Heddle*, Phil. Mag., IV. xiii. 50, 1857, xv. 28, 1858.

Orthorhombic. $I \wedge I = 90° \, 40'$; $O \wedge 1\text{-}\bar{\imath} = 144° \, 9'$: $a : b : c = 0.7225 : 1 : 1.0117$. Observed planes, as in the annexed figure, with also a very low macrodome, nearly coincident with O, having the summit angle 177° 35, Naumann. $O \wedge 2\text{-}\breve{\imath} = 125°$, $i\text{-}\breve{\imath} \wedge I = 134° \, 40'$. Cleavage: $i\text{-}\breve{\imath}$ easily obtained; $i\text{-}\bar{\imath}$ less so; O in traces. Twins: cruciform, having the vertical axis in common, and $i\text{-}\breve{\imath}$ of one part coincident with $i\text{-}\bar{\imath}$ of the other; one of the pair of prismatic planes in each broader than the other. Also columnar, structure radiated; in radiated spherical concretions; also amorphous and compact.

391



H.=5—5·5. G.=2·3—2·4; 2·35—2·38, fr. Seeberg, Zippe; 2·357, fr. Hauenstein, Ramm. Vitreous, more or less pearly. Snow-white; impure varieties brown. Streak uncolored. Transparent—translucent. Fracture uneven. Brittle. Pyroelectric. Double refraction weak; optic-axial plane parallel to O; bisectrix positive, normal to $i\text{-}\breve{\imath}$; divergence 82°—82½° for red rays, from Dumbarton; Descl.

Var.—1. *Ordinary.* (*a*) In regular crystals, usually more or less rectangular in outline. (*b*) in slender prisms, often vesicular to radiated. (*c*) Radiated fibrous. (*d*) Spherical concretions, consisting of radiated fibres or slender crystals. (*e*) Massive, granular to impalpable, and white to reddish-brown.

2. *Mesole* (*Faröelite* of Heddle), the original from Faröe, occurs in spherical concretions, consisting of lamellar radiated individuals, pearly in cleavage. The component crystals gave Heddle, for a vertical prism, 127° 20′, which is within 8′ of the corresponding angle in thomsonite; and Descloizeaux regards the two as optically identical. It occurs with mesolite and apophyllite, and probably owes its slight excess of silica to mixture with the former of these minerals or else with free silica. Mesole was long since referred to thomsonite by Haidinger.

Scoulerite R. D. Thomson, from Port Rush, Antrim, is mesole in structure. It has, Dr. Thomson observes, "the same composition as thomsonite, with only (according to an analysis by R. D. Thomson) rather less alumina, and 6½ p. c. of soda. The analysis has not been published.

3. *Chalilite* Thomson, is a compact variety, of a reddish-brown color, from the Donegore Mts., Antrim. Thomson described it in his Mineralogy (i. 324) as having G.=2·252, and as containing 9 p. c. of sesquioxyd of iron (most improbable with so low sp. gr.). In the Phil. Mag. for 1840 (xvii. 408), he describes apparently the same brown "uncrystallized" mineral as having G.=2·29, with "the same constitution as the Kilpatrick thomsonite, according to an analysis by R. D. Thomson"—an analysis not published. He gives the locality, Ballimony, Antrim. Von Hauer analyzed the chalilite, and found considerable magnesia with only a trace of iron. Greg & Lettsom observe (Min., 160) that the *scoulerite* graduates into the compact chalilite. In view of the facts, it can hardly be doubted that it is impure thomsonite.

Ozarkite is a massive thomsonite, as shown by Smith and Brush, either granular or compact and of a white color, with G.=2·24.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=1 : 3 : 4 : 2½; corresponding to 2 $\ddot{\mathrm{S}}\mathrm{i}$, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, (⅔ $\dot{\mathrm{C}}\mathrm{a}$+⅓ $\dot{\mathrm{N}}\mathrm{a}$), 2½ $\dot{\mathrm{H}}$= Silica 36·9, alumina 31·6, lime 12·9, soda 4·8, water 13·8=100. 8. Iceland	41·00	31·66	10·73	4·50	12·11=100·00 Kobell. G.=2·17
9. B. of Fundy	41·26	29·60	11·71	5·29	12·73=100·59 How.
10. C. Blomidon	41·64	30·52	9·21	4·95	13·11, $\dot{\mathrm{K}}$ 0·44=99·87 Marsh.

O. ratio, according to Berzelius, 1 : 3 : 5 : $\frac{8}{3}$. 1 : 3 : 4½ : 2½ corresponds better with ana. 3, 5, 6, 8, and this varies but little from the composition of thomsonite.

Dr Thomson found for his *chalilite* (l. c.), $\ddot{\mathrm{S}}\mathrm{i}$ 36·56, $\bar{\mathrm{A}}\mathrm{l}$ 26·20, $\bar{\mathrm{F}}\mathrm{e}$ 9 28, $\dot{\mathrm{C}}\mathrm{a}$ 10·28, $\dot{\mathrm{N}}\mathrm{a}$ 2·72, $\dot{\mathrm{H}}$ 16·66=101·70. Von Hauer obtained (Jahrb. G. Reichs., 1853) $\ddot{\mathrm{S}}\mathrm{i}$ 38·56, $\bar{\mathrm{A}}\mathrm{l}$ 27·71, $\bar{\mathrm{F}}\mathrm{e}$ *tr.*, $\dot{\mathrm{M}}\mathrm{g}$ 6·85, $\dot{\mathrm{C}}\mathrm{a}$ 12·01, $\dot{\mathrm{H}}$ 14·32.

The Hauenstein mineral (formerly called *mesolite* of Hauenstein) occurs mixed with natrolite, and this accounts for the results of Freissmuth's analysis (Schw. J., xxv. 425), which differ widely from Rammelsberg's later results (anal. 8).

Pyr., etc.—The Mittelgebirge mineral changes but slightly in moist or dry air, according to Damour; after two hours at 280° C. it loses 6·1 p. c., and very slowly regains the water lost in the open air, the loss being reduced to 1·5 p. c. after forty hours. At a red heat the loss is 13·3 p. c., and the mineral becomes fused to a white enamel. B.B. fuses with intumescence at 2 to a white enamel. Gelatinizes with muriatic acid.

Obs.—Found in cavities in lava and other igneous rocks; and also in some metamorphic rocks, with elæolite.

Thomsonite occurs near Kilpatrick, and at Kilmalcolm and Port Glasgow, Scotland, in amygdaloid; in the lavas of Somma (*comptonite*); in basalt at the Pflasterkaute in Saxe Weimar; at Seeberg and elsewhere in Bohemia, in the cavities of clinkstone; in the Cyclopean islands, Sicily, with analcite and phillipsite; in Faröe; in phonolite at Hauenstein; in Hungary, near Schemnitz; the Tyrol, at Theiss; at Monzoni, Fassa; in straw-yellow needles (*carphostilbite*) at the Berufiord, Iceland, G.=2·362.

Long, slender, prismatic crystallizations, of a grayish-white color, are obtained at Peter's Point, Nova Scotia, where it is associated with apophyllite, mesotype, laumontite, and other trap minerals; fibrous radiated and amorphous (*ozarkite*) at Magnet Cove, in the Ozark Mts., Arkansas, in cavities in elæolite (from the alteration of which it has apparently resulted), with slender prisms of apatite.

Mesole is from the cave of Nalsöe, island of Faröe; Disco I., Greenland; Annaklef, Sweden; a few miles west of C. Blomidon, Bay of Fundy, near the small village of Ft. George.

On twin crystals, see H. Guthe, 14th Jahresb. Ges. Hannover, Jahrb. Min. 1865, 479.

PICROTHOMSONITE *Meneghini & Bechi* (Am. J. Sci., II. xiv. 63, 1852). Like thomsonite in form, and near it in composition. The soda is replaced by magnesia, and possibly as a result of alteration. Occurs in radiated masses, laminated in structure, and cleaving with equal ease parallel to two sides of a rectangular prism; H.=5; G.=2·278; lustre pearly; white; transparent in small fragments; very fragile.

COMP.—$(\dot{\mathrm{C}}\mathrm{a}, \dot{\mathrm{M}}\mathrm{g})^3 \ddot{\mathrm{S}}\mathrm{i}+2\frac{1}{2}\ \bar{\mathrm{A}}\mathrm{l}\,\ddot{\mathrm{S}}\mathrm{i}+4\frac{1}{2}\ \dot{\mathrm{H}}$, Bechi. Analysis: $\ddot{\mathrm{S}}\mathrm{i}$ 40·36, $\bar{\mathrm{A}}\mathrm{l}$ 31·25, $\dot{\mathrm{M}}\mathrm{g}$ 6·26, $\dot{\mathrm{C}}\mathrm{a}$ 10·99, $\dot{\mathrm{N}}\mathrm{a}$, $\dot{\mathrm{K}}$ 0·29, $\dot{\mathrm{H}}$ 10·79=99·94. B.B. fuses to a white enamel, with intumescence. Dissolves in cold acids and gelatinizes. Occurs with caporcianite in the gabbro rosso of Tuscany. The name, from πικρός, *bitter*, and thomsonite, alludes to the magnesia present.

378. NATROLITE. Zeolit pt., Zeolites crystallisatus, prismaticus, capillaris (fr. Gustafsberg), *Cronst.*, Min., 102, 1758; Z. albus fibrosus, capillaris, etc. (fr. Iceland and Gustafsb.), *v. Min., ii. b 303, 1812. Radiolith *Esmark*, Hunefeld, Schw. J., li. 361, 1828. Brevicit (fr. Brevig) *P. Ström*, Jahresb., xiv. 1834. Lehuntite *Thomson*, Min., i. 338, 1836. Eisen-Natrolith *C. Bergemann*, Pogg., lxxxiv. 491, 1851; Iron-Natrolite. Savite *Meneghini*, Am. J. Sci., II. xiv. 64, 1852. Galaktit *Haid.*, Kenng. Ber. Ak. Wien, xii. 290, 1854, xvi. 157, 1855. Fargite *Heddle*, Phil. Mag., IV. xiii. 50, 1857. Palæo-Natrolith *Scheerer*, Pogg., cviii. 416, 1859.

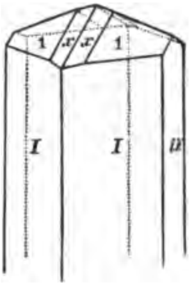
Orthorhombic. $I \wedge I=91°$, $O \wedge 1\text{-}\bar{\imath}=144°\ 23'$; $a : b : c=0{\cdot}35825 : 1 : 1{\cdot}0176$. Observed planes: prismatic, I, $i\text{-}\breve{\imath}$; octahedral, 1, $1\text{-}\frac{\overline{11}}{10}$ (x), $3\text{-}\breve{\imath}$ (between 1 and $i\text{-}\breve{\imath}$). $I \wedge i\text{-}\breve{\imath}=134°\ 30'$, $1 \wedge 1$, ov. x,$=143°\ 20'$, adj.$=142°\ 40'$, $I \wedge 1=116°\ 40'$, $x \wedge x=146°\ 28'$, $1 \wedge 3\text{-}\breve{\imath}=153°\ 30'$. Crystals usually slender, often acicular; frequently interlacing, divergent, or stellate. Also fibrous, radiating, massive, granular, or compact.

392



H.=5—5·5. G.=2·17—2·25; 2·249, Bergen Hill, Brush. Lustre vitreous, sometimes inclining to pearly, especially in fibrous varieties. Color white, or colorless; also grayish, yellowish, reddish to red. Streak uncolored. Transparent—translucent. Double refraction weak; optic-axial plane *i*-ī; bisectrix positive, parallel to edge *I*/*I*; axial divergence 94°—96°, red rays, for Auvergne crystals; 95° 12′ for brevicite; Descl.

Comp.—O. ratio for Ṙ, R̶, S̈i, Ḣ=1 : 3 : 6 : 2; corresponding to 3 S̈i, A̶l, Ṅa, 2 Ḣ=Silica 47·2, alumina 27·0, soda 16·3, water 9·5=100.

Var.—1. *Ordinary.* Commonly either (*a*) in groups of slender colorless prisms, often acicular, with *I* ∧ *I*=91°, Haid., 91° 35′, G. Rose, and 1 ∧ 1=143° 20′, Haid, 144° 40′, G. R., 143° 33′, Phillips; or (*b*) in fibrous divergent or radiated masses, vitreous in lustre, or but slightly pearly (these radiated forms often resemble those of thomsonite and pectolite); often also (*c*) solid amygdules, usually radiated fibrous, and somewhat silky in lustre within; and (*d*) rarely compact massive.

Galactite is ordinary natrolite, occurring in colorless acicular crystallizations in southern Scotland, instituted as a species on an erroneous analysis. *Fargite* is a red natrolite from Glen Farg (anal. 24), containing, like galactite, about 4 p. c. of lime.

Bergmannite (=*spreustein*, *brevicite*, *radiolite*, *palæo-natrolite*) is natrolite from the zircon-syenite of southern Norway, near Brevig, on the Langesundfiord, occurring fibrous, massive, and in long prismatic crystallizations, and from white to red in color. *I* ∧ *I*=91°, G. Rose; 90° 54′, Kenngott; and 1 ∧ 1=142° 55′, G. Rose, 143° 26′, Kenngott; and 1 ∧ 1, side, =142° 49′, Kenng. The reddish varieties are impure from mixture with disseminated diaspore, as shown by Scheerer, and hence the variations from natrolite in composition. The radiolite is in radiated masses, and compact fibrous nodules, of a grayish color, from Eckefiord, having G.=2·275—2·286. These minerals result from the alteration of elæolite, cancrinite, and oligoclase, according to Blum and Sæmann & Pisani. The planes 3-3̆ occur on brevicite (G. Rose). *Crocalite*, from the Ural, is a red zeolite, identical with the bergmannite of Laurvig; occurs in small amygdules, and is fibrous or compact.

Savite, according to Sella's crystallographic and other observations (N. Cimento, 1858), is nothing but natrolite, occurring in slender colorless prisms of the same angles. Sella found *I* ∧ *I*=91°, *I* ∧ ½=116° 35′, ½ ∧ ½, macr., =143° 10′. It comes from a serpentine rock at Mt. Caporciano, Italy, and specimens are ordinarily not pure from serpentine. Meneghini states that H.=3·5 and G.=2·45. See for composition below.

2. *Iron-natrolite* (Eisennatrolith *Bergm.*) is a dark green opaque variety, either crystalline or amorphous, in which a fourth of the alumina is replaced by sesquioxyd of iron (anal. 30); it has H.=5; G.=2·353. Occurs with the Brevig brevicite.

Analyses: 1, Klaproth (Beitr., v. 44); 2, Fuchs (Schw. J., viii. 353, xviii. 8); 3, Riegel (Jhrb. Pharm., xiii.); 4, 5, Fuchs (l. c.); 6, Thomson (Min., i. 317); 7, v. Kobell (J. pr. Ch., xiii. 7); 8, C. G. Gmelin (Pogg., lxxxi. 311); 9, 10, Scheerer (Pogg., lxv. 276); 11, Sieveking, 12, Scheerer (Pogg., cviii. 433); 13, Scheerer (Pogg., lxv. 276); 14, Soudén (Pogg., xxxiii. 112); 15, 16, Körte (G. [a] With a little potash.

Scheerer has shown (Pogg., cviii. 416) that the bergmannite and brevicite, when of a red or reddish color, contain 4 to 7 p. c. of diaspore (a kind containing some iron). The specimen for anal. 12 contained 6¾ p. c.; and, allowing for this, the analysis becomes $\ddot{Si}$ 47·47, $\ddot{\bar{Al}}$ 26·83, $\ddot{\bar{Fe}}$ 0·60, $\dot{Ca}$ 0·88, $\dot{Na}$ 14·42, $\dot{H}$ 9·61=99·81. This fact explains the discrepancies in other analyses.

Savite afforded Bechi (l. c.) $\ddot{Si}$ 49·17, $\ddot{\bar{Al}}$ 19·66, $\dot{Mg}$ 13·50, $\dot{Na}$ 10·52, $\dot{K}$ 1·23, $\dot{H}$ 6·57=100·67. Sella suggests that the magnesia may come from the associated serpentine.

Pyr., etc.—The Auvergue natrolite undergoes, according to Damour, no loss in dried air. At 240° C. it loses nearly all its water and becomes milky and opaque; and if afterward exposed to the free air, it regains all it had lost, excepting its transparency and firm texture; if again heated, it loses its water at about 90° C. In the closed tube whitens and becomes opaque. B.B. fuses quietly at 2 to a colorless glass. Fusible in the flame of an ordinary stearine or wax candle. Gelatinizes with acids.

Obs.—Occurs in cavities in amygdaloidal trap, basalt, and other igneous rocks; and sometimes in seams in granite, gneiss, and syenite. It is found in the *graustein* of Aussig and Teplitz in Bohemia; in fine crystals at Puy de Marman and Puy de la Piquette in Auvergne; at Alpstein, near Sontra in Hesse; Monte Baldo, Tyrol; Fassathal, Tyrol; Kapnik in Hungary; Dellys in Algeria; Högau in Würtemberg (the Faserzeolith *W.*), in yellowish radiated masses; etc. In red amygdules (crocalite) in amygdaloid of Ireland, Scotland, and the Tyrol; the amygdaloid of Bishoptown (galactite), acicular crystals, several inches long; at Glen Farg in Fifeshire; in Dumbartonshire; in Renfrewshire; at Glenarm in the county of Antrim; at Port Rush; and at Magee Island, near Larne, Ireland.

In North America, natrolite occurs in the trap of Nova Scotia, at Gates' mountain, Cape d'Or, Swan's Creek, Cape Blomidon, Two Islands; at Bergen Hill, N. J.; sparingly at Chester, Ct.; at Copper Falls, Lake Superior, in crystals, sometimes on native copper; also on New York Island.

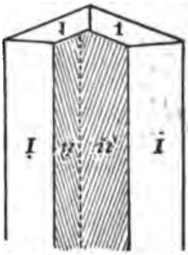
Named *Mesotype* by Haüy, from μέσος, *middle*, and τύπος, *type*, because the form of the crystal—in his view a square prism—was intermediate between the forms of stilbite and analcite. *Natrolite*, of Klaproth, is from *natron*, *soda*; it alludes to the presence of soda, whence also the name *soda-mesotype*, in contrast with scolecite, or *lime-mesotype*. Schumacher's name *bergmannite*, after Bergmann, dates from the same year (1801) with Haüy's *mesotype*.

Alt.—Occurs altered to prehnite. Iron-natrolite is probably an altered variety.

379. SCOLECITE. Skolezit *Gehlen & Fuchs*, Schw. J., viii. 361, 1813. Mesotype pt. Fibrous Zeolite pt. Lime-Mesotype. Poonahlite *Brooke*, Phil. Mag., x. 110, 1831. Punahlit *Germ.*

Monoclinic. *C*=89° 6′, *I* ∧ *I*=91° 36′, *O* ∧ 1-*ì*=161° 16½′; *a* : *b* : *c*= 0·3485 : 1 : 1·0282. Observed planes: *O*; prismatic, *I*, *i-ì*, *i-i* (only as composition-face), *i*-2; hemidome, 1-*i*; hemioctahedral, 1, –1, 3. 1 ∧ 1=144° 40′, –1 ∧ –1=144° 20′, *I* ∧ 1=116° 27′, *I* ∧ –1=143° 28′, *i-ì* ∧ 1=107° 40′, *i-ì* ∧ –1=107° 56′. Crystals long or short prisms, or acicular, rarely well terminated, and always compound. Twins: composition-face *i-i* (orthod.); striæ on *i-ì* meeting along a vertical line in an angle of 24° to 26°, the lines converging downward on the implanted crystals. Cleavage: *I* nearly perfect. Also in nodules or massive; fibrous and radiated.

393



H.=5–5·5. G.=2·16–2·4. Lustre vitreous, or silky when fibrous. Transparent to subtranslucent. Pyroelectric, the free end of the crystals the antilogue pole. Double refraction weak; optic-axial plane normal to *i-ì*; divergence 53° 41′, for the red rays; bisectrix negative, parallel to *i-ì*; plane of the axis of the red rays and their bisectrix inclined about 17° 8′ to *i-i*, and 93° 3′ to 1-*i*.

Var.—*a.* In acicular crystals. *b.* Fibrous, radiated. *c.* Massive. *I* ∧ *I*=91° 22′, Phillips and Descl.; 91° 35′, G. Rose. *I* ∧ 1=116° 34′, Descl.; 117° 10′, Phillips. 1 ∧ 1=144° 40′, Rose and Descl.; 144° 15′, Rose. *Poonahlite* of Brooke, from Poonah, Hindostan, has the angle *I* ∧ *I*=91° 49′, Kenngott.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=1 : 3 : 6 : 3; corresponding to 3 $\ddot{\mathrm{S}}\mathrm{i}$, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$, $\dot{\mathrm{C}}\mathrm{a}$, 3 $\dot{\mathrm{H}}$=Silica 45·8, alumina 26·2, lime 14·3, water 13·7=100. Pyr., etc.—According to Damour, Iceland columnar masses lost nothing in dried air; nothing until the heat applied exceeded 100° C.; at 300° it had lost 5 p. c., which it regained in moist air; at a dull red heat the loss was 12 p. c., and it was no longer hygroscopic; at a bright red it lost 13·9 p. c., and became after intumescence a white enamel. B.B. sometimes curls up like a worm (whence the name from σκώληξ, *a worm*, which gives *scolecite*, and not *scolesite* or *scolezite*); other varieties intumesce but slightly, and all fuse at 2—2·2 to a white blebby enamel. Gelatinizes with acids like natrolite.

Obs.—Occurs in the Berufiord, Iceland, where the crystals often exceed two inches in length, and are occasionally a quarter of an inch thick. It has also been met with in amygdaloid at Staffa; in the Isle of Mull; in Skye, at Talisker; near Eisenach in Saxony; near the Vietsch Glacier, Valais; near Poonah, in the Syhadree mountains, Hindostan; in Greenland; at Pargas, Finland; in Auvergne; the valley of Cachayual, in Chili.

R. Hermann states (J. pr. Ch., lxxii. 26) that he took a white amorphous plastic mass from a crevice in the columnar basalt of Stolpen, Saxony, and put it away in a box; and that after a long time, on opening the box, he found there, not the amorphous mass, but a group of white acicular crystals, which had all the aspect of scolecite.

380. **Ellagite** *A. Nordenskiöld* (Beskrifn., etc., 155, 1855). Regarded by Rammeisberg as a *ferriferous* natrolite. Occurs in yellow, brownish, or reddish-yellow crystalline masses; crystals cleavable in two directions with the intersections near 90°; opaque to subtranslucent; pearly on a cleavage surface. Igelström obtained (Ramm. Min. Ch., 860) S̈i 47·73, Ⱥl 25·20, F̶e 6·57, Ċa 8·72, Ḣ 12·81=101·03, which, taking the iron as protoxyd, as the excess suggests, gives the O ratio 1 : 3·1 : 6·5 : 3, or 1 : 3 : 6 : 3, and the general constitution, therefore, of natrolite. B.B forms a white enamel.

381. MESOLITE.

Fuchs & Gehlen, Schw. J., viii. 353, xviii. 16, 1816. Mesotype pt. Fibrous Zeolite pt. Mehl-Zeolith pt. Lime-and-Soda Mesotype. Antrimolite *Thom.*, Min., i. 326, 1836. Harringtonite *Thom.*, Ed. N. Phil. J., xvii. 186, 1834.

Triclinic? Descl.; but nearly isomorphous with scolecite, and similar in acicular crystallizations. $I \wedge I'$=88° to 88° 15′, and 91° 41′ to 92°; terminal angles of pyramid 142°—143°, and 146°—146° 10′, the latter between faces of the two united halves. Cleavage: I and I' perfect. Crystals always twins; plane of composition one or both vertical diagonal planes. In more or less divergent groups or tufts, often very delicate; lateral planes commonly vertically striated. Also massive; nodules or masses usually silky fibrous or columnar; often bristled with capillary crystals; sometimes consisting of interlaced fibres; rarely stalactitic, radiated fibrous within; occasionally cryptocrystalline, porcelain-like.

H.=5. G.=2·2—2·4; 2·39, Iceland. Lustre of crystals vitreous; of fibrous massive more or less silky. Color white or colorless, grayish, yellowish. Fragile. Transparent—translucent; opaque, when amorphous. Brittle, but tough when cryptocrystalline. Optical characters different from those of scolecite, and compatible only with a triclinic form, Descl.

Var.—Besides (*a*) the ordinary acicular and capillary crystallizations, divergent tufts (less delicate commonly than those of natrolite, but sometimes downy), and fibrous nodules or masses, mesolite occurs (*b*) in fibrous stalactites, with the fibres radiating from the centre—the variety called *Antrimolite* by Thomson, from Antrim, Ireland, having H.=3·5—4, G.=2·096; also (*c*) amorphous, chalk-white, like an almond in lustre, opaque and tough, with H.=5—5·5, and G.=2·21, the variety named *Harringtonite* by Thomson, also from Antrim; G.=2·174, Haughton. According to Kenngott, the prismatic fibres of the antrimolite have $I \wedge I$=92° 13′, and two vertical edges are bevelled by a prism of 150° 30′.

Comp.—O. ratio for Ṙ, R̶, S̈i, Ḣ=1 : 3 : 6 : 3; corresponding to 3 S̈i, Ⱥl, (⅔ Ċa+⅓ Ṅa), 3 Ḣ= Silica 45·6, alumina 26·0, lime 9·5, soda 5·2, water 13·7=100. Pyr., etc.—Yields water in the closed tube. B.B. becomes opaque, swells up into vermicular forms, but not in so marked a manner as scolecite, fusing easily to a blebby enamel. Gelatinizes with muriatic acid (Fuchs).

Obs.—Occurs in amygdaloid and related rocks. The fibrous kinds, especially the coarser, are usually a little less smoothly or neatly fibrous than those of natrolite. On Skye, in delicate interlacing crystals called *cotton-stone*, and in feathery tufts, and in solid masses consisting of radiating crystals; in downy tufts and other forms at Naalsöe on Faröe; also with chabazite in Eigg; near Edinburgh and Kinross, and at Hartfield Moss, in Scotland; in Antrim, at the Giant's Causeway, in acicular crystallizations; also at Ballintoy in Antrim, stalactitic (antrimolite), investing yellow calcite, or chabazite; in Antrim, in veins of amorphous mesolite (harringtonite), at Portrush and at the Skerries; and at Magee Island, and Agnew's Hill, 5 m. W. of Larne; also at other localities, as stated above.

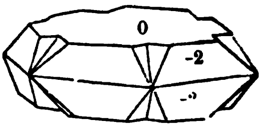
In the North Mountain of King's County, and Gates' Mountain, of Annapolis Co., N. Scotia, with faröelite, in masses, sometimes large (one reported as large as a man's head), usually within fine fibrous, radiated, and somewhat plumose; also at Cape Blomidon.

382. LEVYNITE. Levyne *Brewster*, Ed. J. Sci., ii 332, 1825. Mesolin *Berz.*, Ed. Phil. J., vii. 6, 1822.

Rhombohedral. *R* ∧ *R*=106° 3′; *O* ∧ *R*=136° 1′; *a*=0·83583. Observed planes, as in the annexed figure, with also -3; -2 ∧ -2, term. edge, =79° 29′, -2 ∧ 2-=125° 14′, *O* ∧ 3=109° 3′, *O* ∧ 2=117° 23′. Cleavage: -2, indistinct. Twins: composition-face *O*, as in chabazite. Crystals often striated; often in druses. Double refraction strong; axis negative.

H.=4—4·5. G.=2·09—2·16. Lustre vitreous. Colorless, white, grayish, greenish, reddish, yellowish. Transparent to translucent.

394



Var.—Levynite occurs in crystals, usually tabular, and presenting the plane *O*, a plane not known in crystals of chabazite. It differs from chabazite also in cleavage. The original crystals were from Dalsnypen, Faröe. *Mesolin* is a white granular material from Faröe, which may be chabazite; it fills small cavities in amygdaloid.

Comp.—O. ratio for Ṙ, R̶̈, S̈i, Ḣ=1 : 3 : 6 : 4 from Damour's analyses; corresponding to 3 S̈i, Ä̶l, (Ċa, Ṅa, K̇), 4 Ḣ. Berzelius's analyses, which are suspected to have been made on a mixture of chabazite and levynite (see Greg & Lettsom, 179), give the ratio of chabazite, 1 : 3 : 8 : 5. Analyses: 1, 2, Berzelius (Jahresb., iii. 146, v. 216); 3, Connel (Phil. Mag., v. 50); 4, 5, Damour (Ann. d. M., IV. ix. 333):

	S̈i	Ä̶l	Ċa	Ṅa	K̇	Ḣ
1. Faröe, *Levynite*	48·00	20·00	8·35	2·86	0·41	19·30, Ṁg 0·4=99·32 Berzelius.

3. Skye, *Levynite*	46·30	22·47	9·72	1·55	1·26	19·51, Ḟe, Ṁn 0·96=102·07 Connel.
4. Iceland, "	45·04	24·04	9·72	1·42	1·63	17·49=99·34 Damour.
5. " "	45·76	23·56	10·57	1·36	1·64	17·33=100·22 Damour.

Pyr., etc.—Iceland crystals, according to Damour, lose 4 p. c. in dried air, and regain all again soon in the free air. When heated, begin to lose water at 70° C.; at 225° the loss is 12 to 13 p. c.; remain hygroscopic up to 360°. The loss is completed at a white heat, when the mineral is a white blebby glass. B.B. intumesces and fuses to a white blebby glass, nearly opaque. Gelatinizes with muriatic and nitric acids.

Obs.—Lines cavities in amygdaloid, and is, with a rare exception, the "*sole tenant* of its druses even though these druses be within a quarter of an inch of others containing chabazite associated with half a dozen other zeolites" (Heddle); it shows thus its distinctiveness from chabazite

Found at Glenarm and at Island Magee, Antrim; near Dungiven, Magilligan, and elsewhere in Londonderry; Hartfield Moss, near Glasgow; at Dalsnypen, Faröe, and on the Island Waagöe; at Godhavn, Disco Island, Greenland; at Onundarfiord, Dyrefiord, and elsewhere in Iceland.

Named after the mineralogist and crystallographer, A. Lévy

383. ANALCITE. Zeolite dure (fr. Etna) *Dolomieu*, F. de St Fond Min. des Volcans, 193, 1784. Würfelzeolith pt. [rest Chabazite] *Emmerling*, Min., 205, 1793; Lenz, i. 241, 1794. [Form. f. 9, described.] Zeolite cubique, Z. leucitique, *Delameth.*, T. T., ii. 307, 308, 1797. Analcime *H.*, Tr., iii. 1801. Analcite *Gallitzin*, Dict. Min., 12, 1801. Isometric. In trapezohedrons, f. 10, also f. 9, and another form similar, excepting a very low pyramid, *m*, *m*, in place of each *O*. Cleavage: cubic, in traces. Also massive granular.

H.=5—5·5. G.=2·22—2·29; 2·278, Thomson. Lustre vitreous. Colorless; white; occasionally grayish, greenish, yellowish, or reddish-white. Streak white. Transparent—nearly opaque. Fracture subconchoidal, uneven. Brittle.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 3 : 8 : 2, corresponding to 4$\ddot{\mathrm{Si}}$, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, $\dot{\mathrm{Na}}$, 2$\dot{\mathrm{H}}$=Silica 54·4, alumina 23·3, soda 14·1, water 8·2=100. Analyses: 1, H. Rose (Gilb. Ann., lxxii. 181); 2, Henry (Pogg., xlvi. 264); 3, Leschner (Breith. Min., 1847, 410); 4, Connel (Ed. J. Pyr., etc.—Yields water in the closed tube. B.B. fuses at 2·5 to a colorless glass. Gelatinizes with muriatic acid.

Breithaupt has found (B. H. Ztg., xxiv. 337) the sp. gr. of the opaque analcite from Lake Superior =2·09, and for the nearly transparent =2·1—2·11. But a microscope shows, as Brush has observed, that the crystals are full of air cavities.

Obs.—The Cyclopean Islands, near Catania, Sicily, afford pellucid crystals (f. 9); also the Tyrol; Scotland, in the Kilpatrick Hills; Bowling, pseudomorphs after laumontite; Glen Farg; near Edinburgh; at Kilmalcolm; the Campsie Hills, etc.; at Antrim, etc., in Ireland; the Faröe Islands; Iceland; the Vincentine, with prehnite, chabazite, apophyllite, etc.; Wessela, near Aussig, Bohemia; at Arendal, in Norway, in beds of iron ore; at Andreasberg, in the Harz, in silver mines.

Nova Scotia affords fine specimens at Martial's Cove, Five Islands, Cape d'Or, Swan's Creek, and Cape Blomidon; crystals like f. 9, 10, occur at Bergen Hill, New Jersey: in gneiss, near Yonkers, Westchester Co., N. Y. (f. 10); at Perry, Maine, with apophyllite. in greenstone; abundant in fine crystals, with prehnite, datolite, and calcite, in the Lake Superior region; in the gangue of the copper, at Copper Falls and north-western mines, and at Michipicoton Island (form 2-2), and also at other mines not now worked.

The name *Analcime* is from ἀνάλκις, *weak*, and alludes to its weak electric power when heated or rubbed. The correct derivative is *analcite*, as here adopted for the species.

Alt.—*Picranalcime* of Meneghini and Bechi (Am. J. Sci., II. xiv. 62) is probably analcite altered by the magnesian process. It occurs in geodes in the gabbro rosso of Tuscany, and also in the steatitic paste of a metalliferous dyke; forms f. 9, 10, with distinct cubic cleavage. H.=5. G.=2·257. Color flesh-red to colophonite-red. Lustre vitreous. *Composition*, according to mean of two analyses by E. Bechi (l. c.), S⃛i 59·11, Ä̶l 22·08, Ṁg 10·12, Ṅa 0·45, K̇ 0·02, Ḣ 7·67=99·45. Formula Ṁg^3 S⃛i^3+3 Ä̶l S⃛i^3+6 Ḣ, Bechi. Associated with calcite, caporcianite, and picrothomsonite.

A somewhat similar compound, a pseudomorph after analcite, has been observed by Guthe (Jahrb. Min., 1863, 590) in the clay-iron ore of Duingen. An analysis by Stromeyer (l. c.) afforded S⃛i 56·7, Ä̶l 21·2, F̶̈e 2·8, Ṅa 9·1, Ḣ 9·8=99·6.

The *Cluthalite* of Thomson (Min., i. 339, 1836) occurs in flesh-red vitreous crystals in amygdaloid at the Kilpatrick Hills. H.=3·5. G.=2·166. Opaque or subtranslucent. Fragile. Analysis afforded S⃛i 51·266, Ä̶l 23·560, F̶̈e 7·306, Ṅa 5·130, Ṁg 1·233, Ḣ 10·553=99·048. It may be altered analcite.

Analcite altered to a mixture of calcite and hydrous silicate of alumina has been observed by Tschermak. Also occurs altered to prehnite.

384. EUDNOPHITE. Eunophit *Weibye*, Pogg., lxxix. 303, 1850.

Orthorhombic. *I*∧*I*=120°, *I*∧1-ī=130°, 1-ī∧1-ī, over *O*,=84° 9′. Form a six-sided prism (*I*, *i*-ĭ) with the dome 1-ī. Cleavage: *O* perfect; *i*-ĭ and *i*-ī, less so. Commonly massive, cleavable.

H.=5·5. G.=2·27. Lustre weak, a little pearly on the cleavage-faces. Color white, grayish, brownish. Streak white. Translucent; in thin laminæ transparent. Optically biaxial; double refraction strong; Descl.

Comp.—O. ratio for Ṙ, R̶̈, S⃛i, Ḣ=1 : 3 : 8 : 2, or the same as for analcite. Analyses by von Borck and Berlin (l. c.):

	S⃛i	Ä̶l	Ṅa	Ḣ
1.	54·93	25·59	14·06	8·29=102·87 Borck.
2.	55·06	23·12	14·06	8·16=100·40 Berlin.

Pyr., etc.—Fuses to a colorless glass. Gelatinizes with muriatic acid.

Obs.—Occurs in a coarse syenite on the island Lamöe, near Brevig, Norway, with catapleiite, leucophanite, mosandrite, etc.

Named from εὔδνοφος, *obscurity*, in allusion to the cloudiness of the mineral.

385. FAUJASITE. *Damour*, Ann. d. M., IV. i. 395, 1842.

Isometric. In octahedrons. Twins: composition-face the octahedral.

H.=5. G.=1·923. Lustre vitreous; sometimes adamantine. Colorless—white; brown externally. Fragile; fracture vitreous and uneven. No action on polarized light.

Comp.—O. ratio for Ṙ, R̶̈, S⃛i, Ḣ=1 : 3 : 9 : 9; corresponding to 4½ S⃛i, Ä̶l, (½ Ċa+½ Ṅa), 9 Ḣ= Silica 45·5, alumina 17·4, lime 4·7, soda 5·2, water 27·2=100.

Analyses: 1, Damour (l. c.); 2, id. (ib., xiv. 67):

		S⃛i	Ä̶l	Ċa	Ṅa	Ḣ
1.	Kaiserstuhl	49·36	16·77	5·00	4·34	22·49=97·96.
2	"	46·12	16·81	4·79	5·09	27·02=99·83.

Pyr., etc.—According to Damour, loses 15 p. c. of water when exposed for one month to dry air, but regains almost all of it in ordinary air in 24 hours. Heated at 50°-55° C. for one hour loses 15·2 p. c.; at 60°-65°, 10·4 p. c.; at 70°-75°, 19·5 p. c., which is almost entirely regained by exposure to air for a few weeks. B.B. fuses with intumescence to a white blebby enamel. Decomposed by muriatic acid without gelatinization.

Obs.—Occurs with augite in the amygdaloid of Kaiserstuhl, Baden. The adamantine lustre sometimes existing is attributed to a thin bituminous coating. Named by Damour after Faujas de Saint Fond.

386. CHABAZITE. Zeolithus albus cubicus Islandiæ *v. Born*, Lithoph. i. 46, 1772. Zeolite en cubes *Faujas*, Volc. Viv., 126, 1778; *de Lisle*, Crist., ii. 40, 1783. Chabazie (fr. Y in l=174 5
X in $\frac{1}{4}^3$, ov. $-\frac{1}{2}$,=130 36
Y in $\frac{1}{4}^3$=155 53

Twins: composition-face O, very common, and usually in compound twins, as in f. 397, 398; 2, c.-face R, rare. Cleavage rhombohedral, rather distinct.

H.=4–5. G.=2·08–2·19. Lustre vitreous. Color white, flesh-red; streak uncolored. Transparent—translucent. Fracture uneven. Brittle. Double refraction weak; in polarized light, images rather confused; axis in some crystals (Bohemia) negative, in others (from Andreasberg) positive; Descl.

Var.—1. *Ordinary*. The most common form is the fundamental rhombohedron, in which the angle is so near 90° that the crystals were at first mistaken for cubes. $R \wedge R = 94° 46'$, Phillips, Haid.: 94° 36', fr. Kilmalcolm, Tamnau; 94° 58', fr. Rübendörfel, id.; 95° 2', fr. Fassa, id.; 94° 24', fr Oberstein, Breith. *Acadialite*, from Nova Scotia (*Acadia* of the French of last century), is only a reddish chabazite; sometimes nearly colorless. In some specimens the coloring matter is arranged in a tesselated manner, or in layers, with the angles almost colorless.

2. *Phacolite* is a colorless variety occurring in twins of mostly a hexagonal form (f. 397), and often much modified so as to be lenticular in shape (whence the name, from φακός, *a bean*); the original was from Leipa in Bohemia; $R \wedge R = 94° 24'$, fr Oberstein, Breith.

3. *Haydenite* is a yellowish variety in small crystals of the form in fig. 396, from Jones's Falls, near Baltimore, Md.; the crystals are often twinned parallel to *R*.

Chabazite crystals discovered by Ulrich in the Okerthal, Harz, in cavities in the granite, have G.=2·189, and their edges scratch glass (v. Rath, Pogg., cxxii. 404).

Comp.—For most chabazite O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}} = 1 : 3 : 8 : 6$; corresponding to 4 $\ddot{\mathrm{Si}}$, $\ddot{\bar{\mathrm{Al}}}$, $(\frac{4}{5}\dot{\mathrm{Ca}} + \frac{1}{5}(\dot{\mathrm{Na}}, \dot{\mathrm{K}}))$, 6 $\dot{\mathrm{H}}$; some, 1 : 3 : 9 : 6, the same in constituents except $4\frac{1}{2}$ $\ddot{\mathrm{Si}}$. For the phacolite, according to Rammelsberg, 1 : 3 : 7 : 5.

Analyses: 1–3, Hofmann (Pogg., xxv. 495); 4, Berzelius (Afh., vi. 190); 5, Rammelsberg (Handw., i. 149); 6, Thomson (Min., i. 334); 7, Connell (Edinb. J., 1829, 262); 8, Durocher (Ann. d. M., III. xix. 585); 9, Genth (Ann. Ch. Pharm., lxvi. 274, 1848); 10, Engelhardt (Ann. Ch. Pharm., lxv. 372); 11, Rammelsberg (2d Suppl., p. 34); 12, 13, A. A. Hayes (Am. J. Sci., II. i. 122); 14, Rammelsberg (Pogg., lxii. 149); 15, Anderson (Ed. N. Phil. J., 1843, 23); 16, Schröder (Jahrb. Min., 1860, 795):

16. Oberstein	50·19	17·45	7·13	2·12	0·62	22·09, $\dot{\mathrm{Ba}}$ 0·48, $\dot{\mathrm{Sr}}$ 0·32=100·40 Schröder

The baryta and strontia of the Oberstein crystals were first detected by spectral analysis; and by the same method the absence of these earths from the Iceland was ascertained.

Delesse obtained in an analysis of haydenite, made on too small an amount of material to be correct (Rev. Sci., xxv. 107), $\ddot{\mathrm{Si}}$ 49·5, $\ddot{\bar{\mathrm{Al}}}$, $\ddot{\bar{\mathrm{Fe}}}$ 23·5, $\dot{\mathrm{Ca}}$ 2·70, $\dot{\mathrm{Mg}}$ *tr.*, $\dot{\mathrm{K}}$ 2·50, $\dot{\mathrm{H}}$ 21·0=99·2. Silliman's analysis (This Min., 2d ed.) is wholly erroneous.

Pyr., etc.—According to Damour, crystals from Dyrefiord, Iceland, and Rübendörfel, Bohemia, lost 7·2 p. c. after 5 mos. in dried air; after some months in the free air again had regained this, and also an excess of 0·15 p. c. Heated for 1 h. to 100° C., the loss was 2·75 p. c.; to 180°, 14 p. c.; to 230°, 17 p. c.; to 300°, 19 p. c.; this loss was reduced to zero in 8 days; at a dull red heat, the loss was 21 p. c., and the mineral was no longer hygroscopic; at a bright red, it lost 22·4 p. c., intumesced, and was partially fused.

Phacolite of Scotland [Ireland?] lost 7 p. c. after 7 mos. in dried air; and 4 months after, in an atmosphere saturated with moisture, it had an excess of 12·5 p. c., which it lost very nearly again in ordinary air. Heated to 100° C., the loss was 3·7 p. c.; to 210°, 15·7 p. c.; to 290°–360°, 18 p. c.; and after 48 hours' exposure to the free air, the amount lost was restored. At a dull red heat, the loss was 22·2 p. c.; at a bright red, 22·8 p. c., and the material was fused to a blebby enamel.

B.B intumesces and fuses to a blebby glass, nearly opaque. Decomposed by muriatic acid, with separation of slimy silica.

Obs.—Chabazite occurs mostly in trap, basalt, or amygdaloid, and occasionally in gneiss, syenite, mica schist, hornblendic schist.

Occurs at the Faröe Islands, Greenland, and Iceland, associated with chlorite and stilbite; at Aussig in Bohemia, in a kind of greenstone (the *graustein* of Werner); at Oberstein, with harmotome; at Annerode, near Giessen; at the Giant's Causeway, Kilmalcolm (some an inch across); Renfrewshire, Isle of Skye, etc.; Poonah in Hindostan, etc. In Nova Scotia, wine-yellow or flesh-red (the last the *acadialite*), associated with heulandite, analcite, and calcite, at Five Islands, Swan's Creek, Digby Neck, Mink Cove, William's Brook. *Phacolite* occurs at Leipa in Bohemia; also at Salesel and Wannow, in Bohemia; in Antrim, Ireland, at Giant's Causeway.

Both massive and incrusted at the Paugatuck stone-quarry, Stonington, Conn., with scapolite, sphene, and apatite; also yellowish-red in North Killingworth, on the Essex turnpike; at Hadlyme, Conn., on gneiss; in syenite at Charlestown, Mass.; also at Chester, Mass., in amygdaloid; at Bergen Hill, N. J., in small crystals; in the same rock at Piermont, N. Y.; in fissures in hornblendic gneiss at Jones's Falls, near Baltimore (*haydenite*), with heulandite. Phacolite has been reported from New York Island.

At Husavic, Iceland, fossil clam shells (Venus) occur in a recent deposit, lined within with small rhombohedrons of chabazite. Daubrée states that crystals occur at the warm springs of Luxeuil, Dept. of Haute Saône, France, as well as at those of Plombières, under conditions which indicate that they were formed through the agency of the warm waters; the temperature at Luxeuil is 115° F., and at Plombières 163° F.

The name *Chabasite* is from χαβάζιος, an ancient name of a stone.

Alt.—The haydenite is often covered with chlorite, and sometimes chlorite takes the place of the crystal.

Altered crystals from the Vogelsgebirge, that had lost part of their protoxyd bases, have been analyzed by Suckow (Verwitt., etc., 148):

	$\dddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{C}}$
Interior	48·40	19·13	1·88	1·47	8·13	21·01	——=100·02.
Exterior	47·29	19·16	5·78	1·50	1·47	21·00	8·20=99·40.

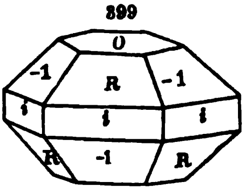
Removing $\dot{\mathrm{C}}\mathrm{a}\,\ddot{\mathrm{C}}$ from the latter, the O. ratios are, for the first, 0·76 : 3 : 8·6 : 6·3; for the second, 0·37 : 3 : 8·4 : 6·2 (Ramm. Min. Ch., 818).

Doranite of Thomson may be altered chabazite, if the analysis is not an incorrect one of the unaltered mineral. It is described as occurring in aggregated crystals, apparently cubic, yellowish-white, and translucent, with G.=2·15; and as consisting of $\dddot{\mathrm{Si}}$ 48·0, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 22·0, $\dot{\mathrm{F}}\mathrm{e}$ 2 75, Mg 13·0, $\dot{\mathrm{C}}\mathrm{a}$ 6·0, $\dot{\mathrm{H}}$ 7·70=99·45. Found in basalt, 2 m. W. of Carrickfergus, Co. Antrim.

387. GMELINITE. Sarcolite *Vauq.*, Ann. d. Mus., ix. 249, 1807, xi. 42. Hydrolithe *Leman*, Cat. Min. de Drée, 18, 1811. Gmelinite *Brooke*, Ed. J. Sci., ii. 262, 1825. Ledererite *C. T. Jackson*, Am. J. Sci., xxv. 78, 1834.

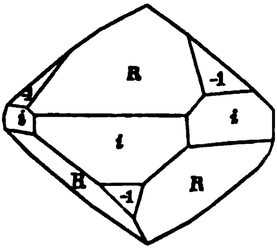
Rhombohedral. *R* ∧ *R*=112° 26′, *O* ∧ *R*=*O* ∧ –1=140° 3′; *a*=0·7254. Observed planes: prismatic, *i*, *i*-2; rhombohedral, *R*, –1; and also the plane 1-2 truncating the edge between *R* and –1. *R* ∧ –1, pyr., = 142° 23′, *R* ∧ –1, bas.,=79° 54′, *R* ∧ 1-2= –1 ∧ 1-2=161° 16′. Crystals usually hexagonal in aspect; sometimes –1 smaller than *R*, and habit rhombohedral; *i* often horizontally striated. Cleavage: *i* perfect. Observed only in crystals, and never as twins.

399



C. Blomidon, etc.

400



C. Blomidon.

H.=4·5. G.=2·04—2·17; 2·099—2·169, fr. C. Blomidon. Lustre vitreous. Colorless, yellowish-white, greenish-white, reddish-white, flesh-red. Transparent to translucent. Brittle. Double refraction weak; axis positive for crystals from Cyprus, negative for those of Andreasberg, the Vicentine, and Glenarm; no evidence of compound structure by polarized light; Descl.

Var.—The angle *R* ∧ –1, ov. *i*, =80° 8′, Brewster, 80° 54′, G. Rose, 80° 6′, Dufren., 79° 44′ Breith., 80° 8′, B. & M., 79° 44′, from Andreasberg, Descl. Plane 1-2 observed only on Andreas berg crystals. The *sarcolite* of Vauquelin is a flesh-red gmelinite from Montecchio-Maggiore in the Vicentin, supposed by Vauquelin, when he used the name, to be identical with the Vesuvian sarcolite.

Ledererite is ordinary gmelinite from Nova Scotia, impure with some free silica. Marsh has shown that it does not differ in the amount of water; and Descloizeaux that it has the same angles, finding *R* ∧ -1, ov. *i*, =80°, and *O* ∧ *R*=140°. Marsh found G.=2·108 (anal. 6), and 2·099 (anal. 7); most of the crystals obtained by him were implanted on quartz.

Comp.—O. ratio for $\dot{R}$, $\ddot{\bar{R}}$, $\ddot{Si}$, $\dot{H}$=1 : 3 : 8 : 6, as in chabazite, G. Rose; corresponding to 4$\ddot{Si}$, $\dddot{\bar{Al}}$, $\frac{1}{2}\dot{Ca}+\frac{1}{2}(\dot{Na}, \dot{K})$, 6$\dot{H}$. Analyses: 1, Connell (Edinb. New Phil. J., 1838); 2, 3, Rammelsberg (Pogg., xlix. 211); 4, Damour (Bull. Soc. G., III. xvi. 675); 5, A. A. Hayes (Am. J. Sci, xxv. 78); 6, 6A, 7, O. C. Marsh (Am. J. Sci., II. xliv. 362):

	$\ddot{Si}$	$\dddot{\bar{Al}}$	$\dot{Ca}$	$\dot{Na}$	$\dot{K}$	$\dot{H}$
1. Glenarm	48·56	18·05	5·13	8·85	0·39	21·66, $\dddot{\bar{Fe}}$ 0·11=98·75 Connell.
2. "	46·40	21·08	3 67	7·29	1·60	20·41=100·45 Rammelsberg.

5. *Ledererite*	49·47	21·48	11·48	3 94	—	8·58, $\dddot{\bar{Fe}}$ 0·14, $\overset{.....}{P}$ 3·48=98·57 Hayes.
6 "	53·71	17·63	6·52	3·10	0·80	17 98=99·74 Marsh.
6A. "	47·19	20·13	7·44	3·54	0·91	20·53=99·74 Marsh.
7. "	51·32	18·45	6·40	[3·48]		20·35=100 Marsh.

Analyses 6, 7, give an excess of silica, and Marsh attributes it to free quartz, visible particles of which were detected by him in the crystals; 6A is the same analysis with 6 after separation of this excess, amounting to about 12 p. c. Both 6 and 7 are of crystals from Cape Blomidon, but from different localities.

Pyr., etc.—According to Damour, the Cyprus gmelinite loses 6 p. c. in dried air; at 100° C. loss 13 p. c., and the amount is regained rapidly in free air; at 230° C. loss 20 p. c.; at a bright red heat 21·5 p. c., and the grains become soldered together. The Irish crystals lose 7·25 p. c. in dried air, which in six months increases to 9·3 p. c.; the loss is reduced to 1·5 p. c. after a few days of exposure. In the closed tube crumbles, giving off much water. B.B. fuses easily (F.=2·5—3) to a white enamel. Decomposed by muriatic acid with gelatinization.

Obs.—Occurs in amygdaloidal rocks at Montecchio Maggiore, and at Castel, in the Vicentine; at Andreasberg, in argillaceous schist, with analcite and heulandite; in Transylvania; at Glenarm and Portrush in Antrim, Ireland; the island of Magee, some crystals ½ in. across; near Larne, flesh-colored; at Talisker in Skye, in large colorless crystals; on the I. of Cyprus, near Pyrgo, of a pale reddish color, and G.=2·07; at Cape Blomidon in Nova Scotia (ledererite), on the north coast, at a point nearly opposite Cape Sharp, in geodes, with analcite and quartz, often implanted on the latter mineral.

Gmelinite is usually considered rhombohedral, and the crystals as twins, secondary to a rhombohedron of 86° 18′. Tamnau makes *R* ∧ *R* as in chabazite, and the pyramidal faces the form $\frac{4}{3}^{2}$. The hexagonal cleavage observed by Rose separates it widely from chabazite.

Named *Gmelinite* after Prof. Ch. Gmelin of Tübingen; *Hydrolite* from the water present; *Ledererite* after Baron Lederer, Austrian Consul at New York. The name hydrolite has the priority, but is objectionable because the mineral is not so eminently hydrous as to make it deserving of the appellation.

388. HERSCHELITE. *Levy*, Ann. Phil., x. 361, 1825. Gmelinite pt. *many authors.* Herschelite *v. Lang*, Phil. Mag., IV. xxviii. 506.

Orthorhombic, v. Lang. *I* ∧ *I*=120°, or nearly, *O* ∧ 1-*ĭ*=139° 23′. Observed planes: *O*, *i-i*, 1-ĭ, 2-ĭ, $\frac{3}{2}$-ĭ, 3-ĭ. *i-ĭ* ∧ 1-*ĭ*=130° 37′, *i-ĭ* ∧ 2-*ĭ*=149° 45′, *i-ĭ* ∧ $\frac{3}{2}$-*ĭ*=155°. Not known in simple forms. Cleavage: basal. Twins: composition-face *I*, the crystals hexagonal tables, with replaced basal edges, but consisting of six sectors from composition. The tables often aggregated, as in prehnite; and also into spherules. Surfaces of planes hardly smooth; *O* often rounded or rough.

H.=5·5. G.=2·06. Lustre weak vitreous. Colorless or white. Translucent; transparent in thin plates. Fracture conchoidal. Optically biaxial, as observed in each sector of the tables, v. Lang; double refraction weak; axial divergence small; bisectrix negative.

Comp.—O. ratio for $\dot{\text{R}}$, $\dddot{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 3 : 8 : 5; corresponding to 4 $\ddot{\text{Si}}$, $\dddot{\text{Al}}$, (½ $\dot{\text{Na}}$+½ $\dot{\text{K}}$), 5 $\dot{\text{H}}$ Near gmelinite in the general form of the crystals and in composition, but the crystals are orthorhombic and not simple, and it contains as its protoxyd bases potash and soda in place of lime and soda. Analyses: 1, 2, Damour (Ann. Ch. Phys., III. xiv. 99); 3, v. Waltershausen (Vulk. Gest., 261):

		$\ddot{\text{Si}}$	$\dddot{\text{Al}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	$\dot{\text{H}}$

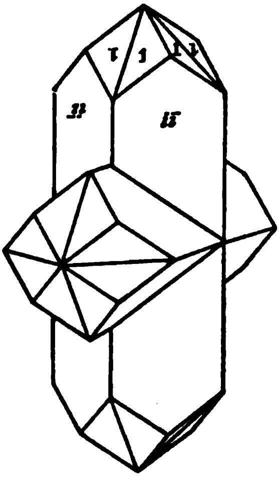
Pyr., etc.—In the closed tube whitens and yields water. B.B. fuses easily to a white enamel. Easily decomposed by acids, yielding semi-gelatinous silica (Damour).

Obs.—Accompanies phillipsite in a lava at Aci Castello, near Aci Reale, Sicily; also at Cyclops, Catania; in basalt near Richmond, in Victoria, Australia, the crystals in mode of twinning and in optical properties like the Sicilian.

389. PHILLIPSITE. *Levy*, Ann. Phil., II. x. 362, 1825. Lime-Harmotome. Kalk-Harmotome *Germ.* Kali-Harmotom, Normalin, *Breith.*, Schw. J., I. 327, 1827, Uib., 32, 1830, Char., 126, 1832. Christianite *Descl.*, Ann. d. M., IV. xii. 373, 1847.

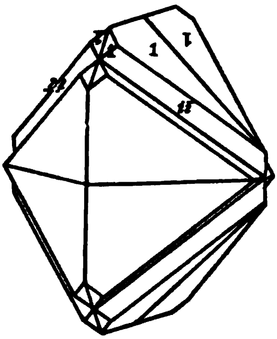
Orthorhombic. $I \wedge I$=91° 12′ and 88° 48′; 1 ∧ 1=121° 20′, 120° 44′ and 88° 40′, Marignac; 120° 42′, 119° 18′, and 90°, Brooke and Miller. Faces 1 and *i-ī* striated parallel to the edge between them. Simple crystals unknown. Twins: (1) composition-face *I*, producing penetration forms like either part of f. 401; (2) cruciform crystals, consisting of two crossing crystals, each a twinned prism (f. 401); (3) cruciform, consisting of three crossing twinned prisms at right angles to one another. The prisms of f. 401 sometimes short, as in f. 402. Crystals either isolated, or grouped in tufts or spheres that are radiated within and bristled with angles at surface.

401



C. di Bove.

402



C. di Bove.

H.=4—4·5. G.=2·2; 2·201, Iceland, Damour, and Sicily, v. Waltershausen. Lustre vitreous. Color white, sometimes reddish. Streak uncolored. Translucent—opaque.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}=1:3:8:5$; corresponding to $4\ddot{\mathrm{Si}}, \dddot{\mathrm{Al}}, (\frac{1}{2}\dot{\mathrm{Ca}}+\frac{1}{2}\dot{\mathrm{K}}), 5\dot{\mathrm{H}}=$ Silica 47·9, alumina 20·5, lime 7·4, potash 6·3, water 17·9=100.

Analyses: 1, 2, Gmelin (Leonh. ZS. Min., 1825); 3, 4, Köhler (Pogg., xxxvii.); 5, Conne (Edinb. Phil. J., xxxv. 1843, 375); 6, 7, Damour (Ann. d. M., IV. ix. 336); 8, Genth (Ann. Ch. Pharm., lxvi. 272); 9, 10, Waltershausen (Vulk. Gest., 263):

[a] Probably as phosphate.

Marignac published as an analysis of the phillipsite of C. di Bove results differing widely from the above. See page 418, under GISMONDITE.

Pyr., etc.—According to Damour, the Kaiserstuhl crystals (mixed with a little faujasite) lose 8 p. c. after a month in dried air, and regain all again in ordinary air in 24 hours. Heated to 50° C. for an hour, the mineral loses 12·3 p. c., and recovers nearly all in 24 hours' exposure to ordinary air, but becomes a powder and opaque (the faujasite remaining transparent). Heated to 150° C., the loss is 16 p. c., and only 0·8 p. c. after exposure again to the air for 4 days. At 250° C., the loss is 18·5 p. c., part of which is due to the faujasite; it is reduced to 9 p. c. in the free air. B.B. crumbles and fuses at 3 to a white enamel. Gelatinizes with muriatic acid.

• **Obs.**—In translucent crystals in amygdaloid, at the Giant's Causeway, Ireland; in small colorless crystals, and in spheroidal groups, in leucitophyr, at Capo di Bove, near Rome; in crystals and radiating masses at Aci Castello and elsewhere in Sicily; among the lavas of Somma; at Stempel, near Marburg; Habichtswalde, near Cassel; Annerode, near Giessen; near Eisenach, in Saxe Weimar; Petersberg, in Siebengebirge; Laubach, in Hesse Darmstadt; in Kaiserstuhl, with faujasite; at Härtlingen, Duchy of Nassau; in Silesia; Bohemia; on the west coast of Iceland, the shores of Dyrefiord. Very small transparent crystals, of recent formation, in the masonry at the hot baths of Plombières, France, observed by Daubrée, are stated by Senarmont to have the angles, and by Descloizeaux the optical characters, of phillipsite.

Named after the English mineralogist, J. Phillips. The name *christianite* was given by Descloizeaux (after Christian VIII. of Denmark) to the Marburg harmotome and crystals from Iceland; and in his Man. Min., 1862, he places all of phillipsite under his name christianite.

On cryst. see Descl., l. c., and Min., i. 399; v. Rath, ZS. G., xviii. 530, from whom the above figures are taken.

390. HARMOTOME.

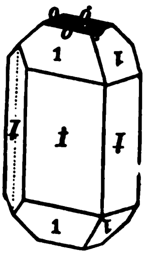
Spatum calcarium cryst. dodecaedrum album, opacum, et lamellis quatuor erectis, etc. (fr. Zellerfeld), *v. Born*, Lithoph., ii. 81, Tab. I., f. 1; Figura hyacinthica, etc.: hæ crystalli non sunt calcareæ, sed siliceæ, *Bergm.*, Opusc., ii. 7, 1780. Hyacinte blanche *Démeste*, Lett. 417, var. 5, 1779. Hyacinte blanche cruciforme *de Lisle*, Crist., ii. 299, pl. iv. f. 119 (good), 1783. Kreuzkristalle *Heyer*, v. Trebra's Erfahrungen, etc., 89; Crell's Ann., i. 212, 1789. Kreutzstein *Wern*, *Karsten*, Lempe's Mag., ii. 58, 59, 1786. Andreasbergolite *Delametherie*, Sciagr., i. 267, 1792. Andreolite *Delameth.*, T. T., ii. 285, 1797. Staurolite *Kirwan*, i. 282, 1794. Ercinite *Napione*, Elem. Min., 239, 1797. Harmotome *Haüy*, Tr., iii. 1801. Pierre cruciforme *Brochant*, i. 311, 1808. Morvenite *Thom.*, Min., i. 351, 1836. Baryt-Harmotome.

Orthorhombic. $I \wedge I=124° 47'$. Observed planes: O, I, 1, 4; 1, 4, and sometimes I, hemihedral.

$O \wedge 1=120° 28'$ $\quad I \wedge 1=149° 32'$ $\quad 1 \wedge I$, adj.,$=121° 6'$
$O \wedge 4=98\ 22$ $\quad 1 \wedge 1$, ov. I,$=119\ 3$ $\quad I \wedge I$, adj.,$=110\ 26$

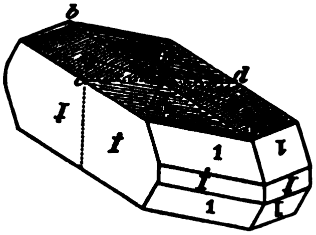
Cleavage: *I*, *O*, easy. Simple crystals unknown. Twins: 1. Composition face *I*, f. 403, 404; f. 403 elongated, and f. 404 shortened in the direction of the vertical axis; both penetration-twins, the two anterior quadrants twinned parallel to *I*, and then these parts prolonged backward in the direction of the shorter diagonal, making a crystal composed of two intersecting crystals, but apparently composed of 4 parts; each part having one narrow plane *I* between two planes 1, and one broad *I*, because the form 1 is hemihedral, the planes occurring only on one of the two basal edges of either half of the prism. 2. Composition the same, but twins double twins, as in f. 405; also in f. 406. which is like f. 405 in a different position, except in the enlargement of planes 1 and the consequent absence of the terminal planes *I*, the large lateral planes corresponding to 4 *O*'s and each reëntering pair to 4 *I*'s. Unknown massive.

403



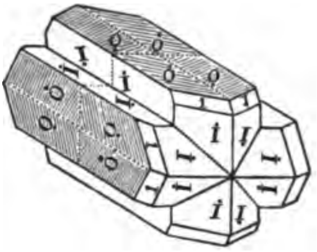
Strontian.

404



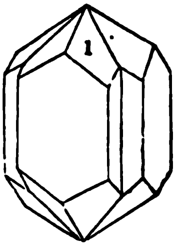
Andreasberg.

405



Andreasberg.

406



H.=4·5. G.=2·44—2·45. Lustre vitreous. Color white; passing into gray, yellow, red, or brown. Streak white. Subtransparent—translucent. Fracture uneven, imperfectly conchoidal. Brittle. Double refraction weak. Optic-axial plane *i-ī* (having the direction of the lines in base in f. 404); acute bisectrix positive. Dispersion inappreciable.

Var.—The variety *morvenite*, from Strontian, Scotland, occurs in transparent and translucent brilliant crystals like fig. 403. G.=2·447, Damour.

Comp.—O. ratio for $\dot{R}$, $\ddot{\bar{R}}$, $\ddot{Si}$, $\dot{H}$=1 : 3 : 10 : 5 (or 4½); corresponding to 5 $\ddot{Si}$, $\ddot{\bar{Al}}$, $\dot{Ba}$, 5 $\dot{H}$= Silica 46·5, alumina 15·9, baryta 28·7, water 13·9=100.

Analyses: 1, Köhler (Pogg., xxxvii. 561); 2, Rammelsberg (Handw., i. 200); 3, id. (Pogg., cx. 624); 4, 5, Köhler (l. c.); 6, Rammelsberg (Pogg., cx. 624); 7, Connel (Ed. N. Phil. J., July, 1832, 33); 8, Damour (Ann. d. M., IV. ix. 336, and C. R., xxii. 745); 9, 10, Damour (Ann. d M., IV. ix. 345):

8. "	47·74	15·68	21·06	——	0·80	0·78	13·19, $\ddot{\bar{Fe}}$ 0·51=99·76 Damour.
9. *Morvenite*	47·60	16·39	20·86	——	0·74	0·81	14·16, $\ddot{\bar{Fe}}$ 0·65=101·21 Damour.
10. "	47·59	16·71	20·45	——	——	——	14·16, $\ddot{\bar{Fe}}$ 0·56=99·47 Damour.

Pyr., etc.—According to Damour, the Scotch harmotome loses 4·8 p. c. by 6 mos.' exposure to dried air. Heated to 100° C. it loses 1·8 p. c. between 100° and 150°, 9·9 p. c.; between 100°

and 190°, 13·5 p. c., and after 24 h. exposure to the ordinary air, what is lost is restored At a dull red heat the loss is 14·65 p. c., and the mineral is disaggregated; the total loss at a bright red heat is 14·70 p. c. B.B. whitens, then crumbles and fuses without intumescence at 3 5 to a white translucent glass. Some varieties phosphoresce when heated. Decomposed by muriatic acid without gelatinizing.

Obs.—Harmotome occurs in amygdaloid, phonolite, trachyte; also on gneiss, and in some metalliferous veins.

Occurs at Strontian, in Scotland, in fine crystals, some an inch through; in a metalliferous vein at Andreasberg in the Harz; at Rudelstadt in Silesia; Schiffenberg, near Giessen; at Schima and Hauenstein in Bohemia; near Eschwege in Hesse; at Oberstein in Birkenfeld, implanted on agate in siliceous geodes; at Kongsberg in Norway; with analcite in the amygdaloid of Dumbartonshire.

Named from ἁρμός, *joint*, and τέμνω, *to cut*, alluding to the fact that the octahedron (made by the planes 1) divides parallel to the plane that passes through the terminal edges.

On cryst. see Levy's Heuland; Descloizeaux, Ann. d. M., IV. ix. 339, and Min., i. 412. The prismatic angle 124° 47′ gives for the prism *i*-2 the angle 87° 26′ and 92° 34′, which is near the angle in phillipsite; so that while phillipsite has the O. ratio for bases and silica of a bisilicate and the angle $I \wedge I$ of pyroxene, harmotome has the O ratio nearly and angle $I \wedge I$ of hornblende. Damour and Descloizeaux show morvenite to be harmotome (Ann. d. M., IV. ix 339).

The name *Andreolite* of Delametherie (derived from the locality at Andreasberg) has the priority, and also *Ercinite* of Napione; but Haüy substituted *harmotoma* of no better signification, and all subsequent mineralogists have followed him.

391. HYPOSTILBITE. *Beudant* (fr. Faröe), Min., ii. 119, 1832. Desmin, Puflerit, *Bukeisen*, Ber. Ak. Wien, xxiv. 286, 1857.

In small concretions, compactly fine fibrous within; also in large radiate-fibrous or columnar masses.

H.=3·5–4. G.=2·1–2·25. Lustre vitreous, strongly so to feebly shining. Color white, sometimes greenish-white. Transparent to translucent.

Comp., Var.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\dddot{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 3 : 9 : 6, corresponding to 4½ $\ddot{\mathrm{Si}}$, $\bar{\dddot{\mathrm{Al}}}$, (⅓ $\dot{\mathrm{Ca}}$+⅔ $\dot{\mathrm{Na}}$), 6 $\dot{\mathrm{H}}$=, if $\dot{\mathrm{R}}=\dot{\mathrm{Ca}}$, Silica 50·3, alumina 19·2, lime 10·4, water 20·1=100. The ordinary hypostilbite contains some soda, with $\dot{\mathrm{Na}}$: $\dot{\mathrm{Ca}}$=2 : 7, nearly; while the variety *puflerite* is without alkalies.

G. of hypostilbite, 2·14 Beudant; 2·18, Haughton; 2·252, Mallet; of puflerite, 2, Bukeisen; 2·21, Damour. In puflerite the fibres have two unequal cleavages, at right angles with one another, with lustre strongly vitreous. Double refraction is strong; axial divergence small; bisectrix parallel to the sides of the fibres and negative; axial plane parallel to the plane of more difficult cleavage; Descl.

Analyses: 1, Beudant (Min., ii. 120); 2, Duménil (ib.); 3, Mallet (Am. J Sci., II. xxii. 179); 4, Haughton (Phil. Mag, IV. xiii. 510): 5, id. (ib., xxxii. 224); 6, Bukeisen (Ber. Ak. Wien, xxiv. 286):

	$\ddot{\mathrm{Si}}$	$\bar{\dddot{\mathrm{Al}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$	
1. Faröe	52·43	18·32	——	8·10	2·41	——	18·70=99·96	Beudant.
2. Dalsnypen	52·25	18·75	——	7·36	2·39	——	18·75=99·50	Duménil.
3. Skye	53·95	20·13	*tr.*	12·86	0·87		12·42=100·23	Mallet.
4. "	52·40	17·98	0·36	9·97	1·40	0·03	17·83=99·97	Haughton.
5. Bombay	52·80	17·12	*tr.*	7·89	2·35	0·07	18·52=98·75	Haughton.
6. *Puflerite*	52·84	16·30	——	11·19	——	——	17·16=98·09	Bukeisen.

Thomson found (Min., i. 345) a "red stilbite" from Dumbarton to contain $\ddot{\mathrm{Si}}$ 52·50, $\bar{\dddot{\mathrm{Al}}}$ 17·32, $\dot{\mathrm{Ca}}$ 11·52, $\dot{\mathrm{H}}$ 18·45=99·79. As he calls the mineral *red stilbite* from Dumbarton, a noted locality of red stilbite familiar to him, and stilbite is easily distinguished by its pearly cleavage, it is far safer to give credit to his mineralogical opinion than to his analysis. Until hypostilbite is announced on good authority from Dumbarton, the analysis may, therefore, be taken only as a coincidence by error.

Pyr., etc.—According to Beudant, intumesces a little, and fuses with difficulty on the edges; attacked by acids without gelatinizing. According to Mallet, gelatinizes readily with acids.

Puflerite, according to Bukeisen, intumesces much, and fuses easily to a snow-white bubbly glass.

Obs.—Hypostilbite occurs on the island of Faröe with stilbite and epistilbite, forming fibrous nodules or concretions in amygdaloid; on the island of Skye, in a similar manner; in the Nerbudda valley, and near Bombay in India, in the same rock, constituting large, fibrous, transparent masses, radiated like natrolite or thomsonite.

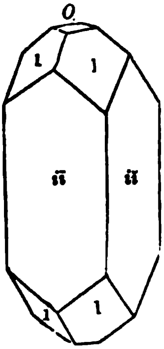
Puflerite occurs at Pufler-loch in the Seiser Alps, Tyrol, in cavities in melaphyre, with analcite and chabazite, and often implanted on these minerals in small concretions.

Named from 'υπο, *below*, and *stilbite*, in allusion to its containing less silica than stilbite. It has been considered altered stilbite.

392. STILBITE. Zeolit pt. *Cronst.*, Ak. H. Stockh., 1756; Zeolites cryst., crystalli ad centrum tendentes (fr. Gustafsberg, etc.), *Cronst.*, 102, 1758. Z. facie Selenitica lamellaris, Blättricher Zeolit pt., *Wall.*, Min., i. 313, 1772. Strahliger Zeolith *Wern.*, Ueb. Cronst., 242, 1780. Strahl-Zeolith (var. of Z.) *Wern.*, 1800, Ludwig., i. 49, 1803. Radiated Zeolite. Zeolite nacrée, Stilbite, *Delameth.*, T.T., ii. 305, 1797. Stilbite (Heulandite incl.) *H.*, J. d M., iii. 66, 1798, Tr., iii. 1801, 1822;=Strahl-Zeolith *Hoffm.*, Min., ii. 237, 1812. Desmine [=Stilbite with Heul. excl.] *Breith.*, Hoffm. Min., iv. b, 40, 1818;=Stilbite *Brooke*, Ed. Phil. J., vi. 112, 1822. Sphærostilbite *Beud.*, Tr., ii. 120, 1832. Syhedrite *Shepard*, Am. J. Sci., II. xl. 110, 1865.

Orthorhombic. $I \wedge I=94°\ 16'$ (whence $i\text{-}2 \wedge i\text{-}2=130°\ 12'$, analogue of $I \wedge I$ in heulandite); $1 \wedge 1$, front, $=119°\ 16'$, side, $114°\ 0'$, $i\text{-}\bar{\imath} \wedge i\text{-}\breve{\imath}=90°$. Brooke and Miller make $O \wedge i\text{-}\bar{\imath}$ or $i\ \breve{\imath}=90°$, $i\text{-}\bar{\imath} \wedge 1=123°$, $i\text{-}\breve{\imath} \wedge 1=120°\ 22'$. Cleavage: $i\text{-}\breve{\imath}$ perfect, $i\text{-}\bar{\imath}$ less so. Forms as in f. 407; more common with the prism flattened parallel to $i\text{-}\breve{\imath}$ or the cleavage-face, and pointed at the extremities; sometimes with the vertical edges replaced by the prism I. Twins: cruciform, composition-face $1\text{-}\bar{\imath}$, rare. Common in sheaf-like aggregations; divergent or radiated; sometimes globular and thin lamellar-columnar.

407



H.=3·5—4. G.=2·094 — 2·205; 2·161, Haidinger. Lustre of $i\text{-}\breve{\imath}$ pearly; of other faces vitreous. Color white; occasionally yellow, brown, or red, to brick-red. Streak uncolored. Transparent—translucent. Fracture uneven. Brittle. Double refraction strong; optic-axial plane $i\text{-}\breve{\imath}$; divergence 50°—55°; bisectrix negative, perpendicular to O: Descl.

Var.—1. *Ordinary.* Either (*a*) in crystals, flattened and pearly parallel to the plane of cleavage, or sheaf-like or divergent groups; or (*b*) in radiated stars or hemispheres, with the radiating individuals showing a pearly cleavage surface. *Sphærostilbite* Beud. is in spheres, radiated within, with a pearly fracture, rather soft externally, but harder at centre, and having G.=2·31. Heddle shows that it is stilbite impure from mixture with mesolite; the original was from Faröe

Comp.—O. ratio 1 : 3 : 12 : 6; corresponding to $6\dddot{\mathrm{Si}}$, $\dddot{\overline{\mathrm{Al}}}$, $\dot{\mathrm{Ca}}$, $6\dot{\overline{\mathrm{H}}}$=Silica 57·4, alumina 16·5, lime 8·9, water 17·2=100. A white silky incrustation on chert, from the hot spring of Olette, eastern Pyrenees, afforded J. Bouis S̈i 57·6, Ä̶l 16·1, Ċa 8·6, Ḣ 17·6=99·9; and Descloizeaux observes that it occurs also in cleavable rectangular prisms like those of stilbite.

Syhedrite of Shepard (l. c.), from trap in the Syhedree Mountains, Bombay, has a greenish color, with G.=2·321; and afforded W. S. Tyler (l. c.) Ä̶l 15·06, Ḟe 2·71, Ṁg 2·46, Ċa 6·45, Ḣ 16·40, the rest, 56·92, undetermined, but supposed to be all silica. Alkalies wanting. It may be an impure stilbite, colored by a chlorite-like mineral.

Pyr., etc.—According to Damour, loses 1·3 p. c. at 100° C.; 13 p. c. between 100° and 150° C.; regaining all lost but 3·1 p. c. after 5 days' exposure to the ordinary air; at 170° C. the loss is 16·2 p. c., which is reduced to 9·2 p. c. after 15 days' exposure. B.B. exfoliates, swells up, curves into fan-like or vermicular forms, and fuses to a white enamel. F.=2—2·5. Decomposed by muriatic acid, without gelatinizing. The *sphærostilbite* gelatinizes, but Heddle says this is owing to a mixture of *mesolite* with the stilbite.

Obs.—Stilbite occurs mostly in cavities in amygdaloid. It is also found in some metalliferous veins, and in granite and gneiss.

Abundant on the Faröe Islands, in Iceland, and on the Isle of Skye, in amygdaloid; also found on the Isle of Arran, Scotland; in Dumbartonshire, at Long Craig, and at Kilpatrick, Scotland, in red crystals; at Kincardine, Kilmalcolm, Campsie, Scotland; at the Giant's Causeway, in the Mourne Mts., etc., Ireland; at Andreasberg in the Harz, and Kongsberg and Arendal in Norway, with iron ore; in the Vendayah Mts., Hindostan, in large translucent crystals having a reddish tinge; also in the Nerbudda valley and in the Bombay Presidency; a brown variety on granite, at the copper mines of Gustafsberg, near Fahlun in Sweden; at Andreasberg, Kongsberg, etc.

Sphærostilbite occurs in minute spheres over faröelite in Skye; at Storr (anal. 13, 14); and at Quiraing, in spheres as large as a pea.

In North America, sparingly in small crystals at Chester and the Charlestown syenite quarries, Mass.; at the gneiss quarry, Thachersville, Conn., in crystals lining cavities in coarse granite; at Hadlyme, in radiated forms on gneiss, associated with epidote, garnet, and apatite; at Phillipstown, N. Y., in crystals or fan-like groups; opposite West Point, in a vein of decomposing bluish feldspar, intersecting gneiss, in honey-yellow crystals; in the greenstone of Piermont, in minute crystals; in scopiform crystals of a dull yellow color, near Peekskill, N. Y.; and at Bergen Hill, New Jersey, in small but bright crystals; also at the Michipicoton Islands, Lake Superior; at Partridge Island, Nova Scotia, forming a perpendicular vein from 3 to 4 inches thick, and from 30 to 50 feet long, intersecting amygdaloid, its colors white and flesh-red; also at Isle Haute, Digby Neck, Gulliver's Hole, Black Rock, Cape Blomidon, Hall's Harbor, Long Point.

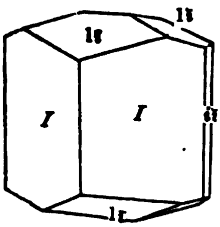
The name *stilbite* is from στίλβη, *lustre*; and *desmine* from δέσμη, *a bundle*. The species stilbite, as adopted by Haüy, included Strahlzeolith *Wern.* (radiated zeolite, or the above), and Blätterzeolith *Wern.* (foliated zeolite, or the species heulandite beyond). The former was the typical part of the species, and is the first mentioned in the description; and the latter (made the variety *stilbite anamorphique*) he added to the species, as he observes, with much hesitation. In 1817, Breithaupt separated the two zeolites, and called the former *desmine* and the latter *euzeolite*, thus throwing aside entirely, contrary to rule and propriety, Haüy's name *stilbite*, which should have been accepted by him in place of desmine, it being the typical part of his species. In 1822 Brooke (apparently unaware of what Breithaupt had done) used *stilbite* for the first, and named the other *heulandite*. In this he has been followed by the French and English mineralogists; while the Germans have unfortunately followed Breithaupt.

Alt.—Stilbite has been observed changed to quartz.

393. EPISTILBITE. Epistilbit *G. Rose*, Pogg., vi. 183, 1826. Monophan *Breith.*, Char., 279, 1823.

Orthorhombic. $I \wedge I=135^\circ\ 10'$, $O \wedge 1\text{-}\bar{i}=144^\circ\ 53'$; $a:b:c=1{\cdot}422:1:2{\cdot}4242$. Observed planes, as in f. 408, with $2\text{-}\breve{i}$ replacing edge $I \wedge 1\text{-}\breve{i}$.

408



1-*ī* ∧ 1-*ī*, top, =109° 46′, 1-*ĭ* ∧ 1-*ĭ*, top, =147° 40′, *I* ∧ 1-*ĭ* =122° 9′, 1-*ī* ∧ 1-*ĭ*=141° 47′. Cleavage: *i*-*ĭ*, very perfect; indistinct in other directions. Face *I* mostly uneven. Generally in twins; composition-face *I*. Also granular.

H.=4—4·5. G.=2·249—2·363. Lustre of cleavage-face pearly; of *I* vitreous. Color white, bluish- or yellowish-white, reddish. Transparent—translucent. Fracture uneven. Double refraction weak; plane of optical axes parallel to *i*-*ĭ*, and bisectrix normal to *i*-*ī*.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 3 : 12 : 5; corresponding to 6 $\ddot{\mathrm{Si}}$, $\dddot{\mathrm{Al}}$, ($\frac{3}{4}$ $\dot{\mathrm{Ca}}$+$\frac{1}{4}$ $\dot{\mathrm{Na}}$), 5 $\dot{\mathrm{H}}$= Silica 59·0, alumina 16·9, lime 7·3, soda 2·0, water 14·8=100. Pyr., etc.—B.B. intumesces and forms a vesicular enamel. Soluble in concentrated muriatic acid without gelatinizing.

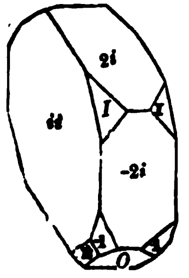
Obs.—Occurs with scolecite at the Berufiord in Iceland; in Faröe; at Poonah in India; in small flesh-colored crystals at Skye; in small reddish crystals, nearly or quite opaque, with stilbite, at Margaretville, N. Scotia, 7 m. E. of Port George (anal. 7; loc. for anal. 8 not precisely known). Reported as occurring with stilbite, apophyllite, etc., at Bergen Hill, N. J.

Parastilbite. Von Waltershausen thus names (l. c., p. 251) a specimen from Borgarfiord, which afforded on analysis $\ddot{\mathrm{Si}}$ 61·87, $\dddot{\mathrm{Al}}$ 17·83, $\dot{\mathrm{Ca}}$ 7·32, $\dot{\mathrm{Na}}$ 2·00, $\dot{\mathrm{K}}$ 1·78 $\dot{\mathrm{H}}$ 9·20=100, for which he deduces the O. ratio 1 : 3 : 12 : 3, and writes the formula $\dot{\mathrm{R}}\ddot{\mathrm{Si}}+\dddot{\mathrm{Al}}\ddot{\mathrm{Si}}^3+3\dot{\mathrm{H}}$. It resembles epistilbite, but gives (Pogg., xcix. 170) 136° 39′ for the angle *I* ∧ *I*.

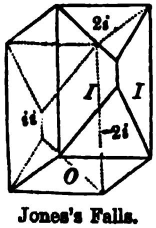
344. HEULANDITE. Blättriger Zeolith *Meyer*, Beschaft. Ges. N. Fr. Berlin, iv. 1779; *Hoffm.*, Bergm. J., 430, 1789. Blätter-Zeolith (var. of Z.) *Wern.*, 1800, Ludw. Min., 49, 1803. Stilbite pt., Stilbite anamorphique, *H.*, Tr., iii. 1801. Euzeolith *Breith.*, Hoffm. Min., iv., b, 40, 1818. Heulandite *Brooke*, Ed. Phil. J., vi. 112, 1822. Lincolnite *Hitchcock*, Rep. G. Mass., 1833, 437, 1835, 662, 1841. Beaumontite *Levy*, C. R., 1839.

Monoclinic. *C*=88° 35′, *I* ∧ *I*=136° 4′, *O* ∧ 1-*ì*=156° 45′; *a* : *b* : *c*= 1·065 : 1 : 2·4785. Observed planes as in the annexed figures.

409



410



Jones's Falls.

O ∧ 2-*i*=116° 20′ *i*-*ì* ∧ -1=106° 32′
O ∧ -2-*i*=114 *i*-*ì* ∧ *I*=111 58
2-*i* ∧ -2-*i*=129 40 -1 ∧ -1=146 56

Cleavage: clinodiagonal (*i*-*ì*) eminent. Also in globular forms; also granular.

H.=3·5—4. G.=2·2, Haidinger; 2·195, Faröe Islands, Thomson; 2·175, Iceland. Lustre of *i*-*ì* strong pearly; of other faces vitreous. Color various shades of white, passing into red, gray, and brown. Streak white. Transparent—subtranslucent. Fracture subconchoidal, uneven. Brittle. Double refraction weak; optic-axial plane normal to *i-ì*; bisectrix positive, parallel to the horizontal diagonal of the base; Descl.

Comp.—O. ratio 1 : 3 : 12 : 5, corresponding to 6 $\ddot{\mathrm{Si}}$, $\bar{\bar{\mathrm{Al}}}$, $\dot{\mathrm{Ca}}$, 5 $\dot{\mathrm{H}}$=Silica 59·1, alumina 16·9, lime 9·2, water 14·8=100. The red color of the Fassa crystals is due, according to Kenngott, to minute crystalline grains of another mineral.

Pyr., etc.—According to Damour, the Faröe mineral loses part of its water in dry air, which it retakes in ordinary air; the loss of the mineral is 2·1 p. c. at 100° C., and 8·7 p. c. between 100° and 150° C.; and this is restored again after 24 hours in the air. At 190° the loss is 12·3 p. c.; and by the end of two months all is regained but 2·1 p. c. B.B. same as with stilbite.

Obs.—Heulandite occurs principally in amygdaloidal rocks. Also in gneiss, and occasionally in metalliferous veins.

The finest specimens of this species come from Berufiord, and elsewhere, Iceland; the Faröe Islands; the Vendayah Mountains, Hindostan. It also occurs in the Kilpatrick Hills, near Glasgow; on the I. of Skye; in the Fassa Valley, Tyrol; Andreasberg, Harz; near Semil and Rodisfort, Bohemia; Poremba, Poland; Marschendorf, Moravia; Neudörfel, near Zwickau, Saxony; Siberia, at Nertschinsk, etc.; in the amygdaloid of Abyssinia. Red varieties occur at Campsie in Sterlingshire, with red stilbite; also in Fassa Valley, Tyrol; and brown in ore beds at Arendal.

At Peter's Point, Nova Scotia, it occurs in amygdaloid, presenting white and flesh-red colors, and associated with laumontite, apophyllite, thomsonite, etc.; also at Cape Blomidon, in crystals an inch and a half in length; at Martial's Cove, Isle Haute, Partridge Island, Swan's Creek, Two Islands, Hall's Harbor, Long Point.

In the United States, with stilbite and chabazite on gneiss, at Hadlyme, Ct., and Chester, Mass.; with these minerals and datolite, apophyllite, etc., in amygdaloid at Bergen Hill, New Jersey; sparingly at Kipp's Bay, New York Island, on gneiss, along with stilbite; at McKinney's quarry, Rittenhouse Lane, near Philadelphia, sparingly; on north shore of Lake Superior, between Pigeon Bay and Fond du Lac; in minute crystals, seldom over half a line long, with haydenite, at Jones's Falls, near Baltimore, on a syenitic schist (Levy's *beaumontite*, which is crystallographically and optically identical with heulandite).

Named after the English mineralogist, H. Heuland.

CERINITE *How* (Ed. N. Phil. J., II. x. 84, 1859) is near heulandite in composition, but is massive, with a subresinous or waxy lustre, H.=3·5, white or yellowish-white color, and it fuses B.B. without intumescence. How obtained, as a mean of two analyses, $\ddot{\mathrm{Si}}$ 57·57, $\bar{\bar{\mathrm{Al}}}$ 12·66, $\bar{\mathrm{Fe}}$ 1·14, $\dot{\mathrm{Mg}}$ 1·87, $\dot{\mathrm{Ca}}$ 9·82, $\dot{\mathrm{K}}$ 0·37, $\dot{\mathrm{H}}$ 15·69=99·12. Forms the thin outer crust of amygdules in trap of the Bay of Fundy, near Black Rock. A pure species could hardly be expected from a massive material in such a condition.

395. BREWSTERITE. *Brooke*, Ed. Phil. J., vi. 112, 1822. Diagonit *Breith.*, Char., 118, 1832.

Monoclinic. *C*=86° 56′, *I* ∧ *I*=136°, *O* ∧ 1-*ì*=157° 14′; *a* : *b* : *c*= 1·0387 : 1 : 2·4715. *O* ∧ *i-i*=93° 4′, *O* ∧ *i-ì*=90°, *O* ∧ *I*=93° 24′, *O* ∧ ⅙-*ì* =176°, ⅙-*i* ∧ ⅙-*ì*=172°, Brooke. From measurements by Mallet, *I* ∧ *I*= 136° 13′, *I* ∧ *i-i*=157° 17′–23′, *I* ∧ *i-ì*=112° 12′–17′, *O* ∧ ⅙-*ì*=175° 49′–55′, ⅙-*ì* ∧ ⅙-*ì*=171° 40′–43′. Cleavage: *i-ì* highly perfect.

Pyr., etc.—According to Damour, brewsterite loses water in unheated dried air, experiencing a loss of weight of 1·65 p. c. in the course of a month. At 100° C., after 2 hours, the loss is 0·2 p. c., but at 130° C. 7·7 p. c., when the mineral while still hot is electric, the crystals mutually attracting; they have become opaque and pearly; by 48 hours' exposure to ordinary air, the loss is reduced to 2·7 p. c. At 190° C., the loss is 8·2 p. c.; this is reduced to zero after 48 hours' exposure; and at 270°, the loss is 10·1 p. c., which is reduced to 1·2 p. c. after 8 days' exposure. At a dull red heat the loss is 12·8 p. c., and at a bright red, 13·3 p. c. B.B. swells up and fuses at 3 to a white enamel. Decomposed by acids without gelatinizing.

Obs.—First observed at Strontian in Argyleshire, with calcite. Occurs also at the Giant's Causeway, coating the cavities of amygdaloid; in the lead mines of St. Turpet; near Freiburg in the Brisgau; at the Col du Bonhomme, S. W. of Mont Blanc, on a quartz rock; near Barèges, in the Pyrenees, in a calcareous schist; and it has been reported from the department of the Isère in France.

Named after Sir David Brewster.

396. MORDENITE. *How*, J. Ch. Soc., II. ii. 100.

In small hemispherical, reniform, or cylindrical concretions. Structure fibrous.

H.=5. G.=2·08. Lustre highly silky. Color white, yellowish, or pinkish. Translucent on the edges. Rather brittle.

Comp.—O. ratio, $\dot{\mathrm{R}}$, $\dddot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}=1:3:18:6$; corresponding to 9 $\ddot{\mathrm{Si}}$, $\dddot{\mathrm{Al}}$, ($\frac{2}{3}$ $\dot{\mathrm{Ca}}+\frac{1}{3}$ $\dot{\mathrm{Na}}$), 6 $\dot{\mathrm{H}}$=$\ddot{\mathrm{Si}}$ 66·92, $\dddot{\mathrm{Al}}$ 12·66, $\dot{\mathrm{Ca}}$ 4·59, $\dot{\mathrm{Na}}$ 2·54, $\dot{\mathrm{H}}$ 13·29=100. Analysis: How (l. c.):

$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
(⅔) 68·40	12·77	3·46	2·35	13·02=100.

The soda includes 0·09 to 0·23 of potash. The silica varied from 67·38 to 69·27.

Pyr., etc.—Yields water. B.B. fuses without intumescence. Not perfectly decomposed by acids.

Obs.—Occurs near Morden, King's Co., Nova Scotia, in trap, with apophyllite, barite, and a prehnite-like mineral; also at Peter's Point, eight miles west, with gyrolite.

APPENDIX TO ZEOLITE SECTION.

397. SLOANITE *Meneghini & Bechi*, Am. J. Sci., II. xiv. 64.

Orthorhombic. $I \wedge I=105°$. Cleavage: *I* very distinct. In radiated masses, with often a fracture transverse to the radiation.

H.=4·5. G.=2·441. Lustre pearly. White. Opaque.

COMP.—O. ratio for $\dot{R}$, $\ddot{\bar{R}}$, $\ddot{\mathrm{Si}}$, $\dot{H}$, from analysis=1 : 5 : 7 : 1=Silica 42·7, alumi-a 34·9, lime 11·4, water 11·0=100. Analysis: Bechi (Am. J. Sci., II. xiv. 64):

$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
42·19	35·00	8·12	2·67	0·25	0·30	12·50=100·76.

PYR., ETC.—Yields water. B.B. fuses without intumescence to a white enamel. Dissolves in the acids even in the cold, and gelatinizes.

From the gabbro rosso of Tuscany.

398. SASPACHITE *Descloizeaux* (Min., i. 420). A *zeolitic* mineral from Saspach in Kaiserstuhl, afforded J. Schill (Jahrb. Min. 1846, 452) $\ddot{\mathrm{Si}}$ 51·50, $\ddot{\bar{\mathrm{Al}}}$ 16·51, $\dot{\mathrm{Ca}}$ 6·20, $\dot{\mathrm{K}}$ 6·82, $\dot{\mathrm{Mg}}$ 1·93, $\dot{\mathrm{H}}$ 17·00 =99·96. Occurs in tufts of fibres and concretions; G.=1·465; H.=4–5; white or colorless; lustre silky to vitreous. Easily soluble in muriatic acid. Occurs in doleryte in cavities, and is often overlaid by faujasite and apophyllite.

III. MARGAROPHYLLITE SECTION.

The Margarophyllites, whose general characteristics are mentioned on page 393, have the crystallization of the micas, and the name alludes to the pearly folia. Massive varieties are, however, much the most common with a large part of the species, and they often have the compactness of clay or wax. Talc, pyrophyllite, serpentine, are examples of species presenting both extremes of structure; while pinite occurs, as thus far known, only in the compact condition.

The proportion of silica varies widely, the oxygen ratio between it and the bases having the limits 3 : 1 and ½ : 1, corresponding to tersilicates at one extreme and the lower of subsilicates at the other. But, reckoning the water, or part of it, among the bases, the species may all be arranged under the heads of Bisilicates, Unisilicates, and Subsilicates; and, although there must be much that is hypothetical in such an arrangement, the method is adopted beyond.

This method of arrangement is in fact no more arbitrary than the common one of making no account of the water. Talc has the oxygen ratio for the silica, bases, 2½ : 1; but, at the same time, it contains water, and holds it even when highly heated, thereby indicating that part, at least, of the water is basic; and with basic water the ratio may be 2 : 1, or that of a true Bisilicate. The arrangement of talc at the head of the Bisilicates appears, therefore, not to be altogether arbitrary. Pyrophyllite is a true alumina talc, it having the same oxygen ratio as talc, and like structure, lustre, greasy feel, and even range of color; and it has its place, therefore, next to talc, among the Bisilicates. Serpentine has not silica enough for a Bisilicate; but, with half of its water basic, it is a Unisilicate. Kaolinite is identical with serpentine in oxygen ratio, as pyrophyllite is with talc, and is similarly a Unisilicate. Pinite has the same ratio, excepting half less of water, and is strictly an alumina-alkali serpentine; and palagonite is another of like ratio and characters. These species, moreover, are all related to the margarodites or hydrous micas.

In the following table the species are distributed under the three heads above mentioned. The catalogue of the species and their formulas in the first two of these subdivisions is followed by a table containing the oxygen ratio for the protoxyds, sesquioxyds, silica, and water, and also, in another column, those for the bases, silica, and water; and under $\dot{H}$ in the latter, a fraction is added in parentheses, which indicates what proportion of the water (when any) is made basic in the formulas.

ARRANGEMENT OF THE SPECIES.

I. BISILICATES.

I. TALC GROUP. Foliated when crystallized.

399. TALC A	$(\frac{1}{5}\dot{H}+\frac{4}{5}\dot{M}g)\dddot{S}i$	$Si\,\Theta\|\Theta_2\|(\frac{1}{5}H_2+\frac{4}{5}Mg)$
B	$(\frac{1}{5}\dot{H}+\frac{4}{5}\dot{M}g)\dddot{S}i+\frac{1}{5}\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{5}H_2+\frac{4}{5}Mg)+\frac{1}{5}aq$
400. PYROPHYLLITE	$(\frac{1}{5}\dot{H}^3+\frac{4}{5}\bar{A}l)\dddot{S}i^3+\frac{1}{15}\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{5}H_2+\frac{4}{5}\beta Al)-\frac{1}{15}aq$
401. PIHLITE	$(\ddot{R}^3,\bar{H}^3,\bar{A}l)\dddot{S}i^3+\frac{3}{10}\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{5}(H_2,K_2,R)+\frac{4}{5}\beta Al)+\frac{1}{5}\bar{H}$

II. SEPIOLITE GROUP. Contain magnesium or aluminum. Known only massive.

402. SEPIOLITE	$(\frac{1}{3}\dot{H}+\frac{2}{3}\dot{M}g)\dddot{S}i+\frac{1}{3}\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{3}H_2+\frac{2}{3}Mg)+\frac{1}{3}aq$
403. APHRODITE	$\dot{M}g\dddot{S}i+\frac{3}{4}\dot{H}$	$Si\,\Theta\|\Theta_2\|Mg+\frac{3}{4}aq$
404. CIMOLITE	$(\frac{1}{3}\dot{H}^3+\frac{2}{3}\bar{A}l)\dddot{S}i^3+\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{3}H_2+\frac{2}{3}\beta Al)+\frac{1}{3}aq$
405. SMECTITE	$(\frac{1}{2}\dot{H}^3+\frac{1}{2}\bar{A}l)\dddot{S}i^3+4\frac{1}{2}\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{2}H_2+\frac{1}{2}\beta Al)+1\frac{1}{2}aq$
406. MONTMORILLONITE	$(\frac{1}{5}\dot{H}^3+\frac{4}{5}\bar{A}l)\dddot{S}i^3+5\dot{H}$	$Si\,\Theta\|\Theta_2\|(\frac{1}{5}H_2+\frac{4}{5}\beta Al)+1\frac{2}{3}aq$

III. CHLOROPAL GROUP. Contain iron in the sesquioxyd state.

407. STILPNOMELANE	$(\ddot{R}^3,(\bar{F}e,\bar{A}l))\dddot{S}i^3+2\dot{H}$	$Si\,\Theta\|\Theta_2\|(R,\beta(Fe,Al))+\frac{2}{3}aq$
408. CHLOROPAL	$(\dot{F}e^3,\bar{F}e)\dddot{S}i+4\frac{1}{2}\dot{H}$	$Si\,\Theta\|\Theta_2\|(Fe,\beta Fe)+1\frac{1}{2}aq$
409. GLAUCONITE		
410. CELADONITE		

	$\ddot{R}$	$\bar{\bar{R}}$	$\dddot{S}i$	$\dot{H}$	$\ddot{R}\bar{\bar{R}}$	$\dddot{S}i$	$\dot{H}$
Talc A	1		$2\frac{1}{2}$	$\frac{1}{4}$	1	$2\frac{1}{2}$	$\frac{1}{4}$
B	1		$2\frac{1}{2}$	$\frac{1}{2}$	1	$2\frac{1}{2}$	$\frac{1}{2}$ ($\frac{1}{4}$)
Pyrophyllite		1	$2\frac{1}{2}$	$\frac{1}{2}$	1	$2\frac{1}{2}$	$\frac{1}{2}$ ($\frac{1}{4}$)
Pihlite	1	8	20	2	1	$2\frac{2}{9}$	$\frac{2}{9}$ ($\frac{1}{9}$)
Sepiolite	1		3	1	1	3	1 ($\frac{1}{2}$)
Aphrodite	1		2	$\frac{3}{4}$	1	2	$\frac{3}{4}$

	$\ddot{R}$	$\bar{\bar{R}}$	$\dddot{S}i$	$\dot{H}$	$\ddot{R}\bar{\bar{R}}$	$\dddot{S}i$	$\dot{H}$
Cimolite		1	3	1	1	3	1 ($\frac{1}{2}$)
Smectite		1	4	4?	1	4	4 ($\frac{1}{4}$)
Montmorillonite		1	$2\frac{1}{2}$	$2\frac{1}{3}$	1	$2\frac{1}{2}$	$2\frac{1}{3}$
Stilpnomelane					1	2	$\frac{2}{3}$
Chloropal		1	2	$\frac{1}{2}$	1	2	$\frac{1}{2}$
Glauconite	1	3	9	3?	1	$2\frac{1}{4}$	$\frac{3}{4}$?

II. UNISILICATES.

IV. SERPENTINE GROUP. Contain magnesium.

411. SERPENTINE	$(\frac{1}{4}\dot{H}+\frac{3}{4}\dot{M}g)^2\dddot{S}i+\frac{1}{2}\dot{H}$	$Si\|\Theta_4\|(\frac{1}{4}H_2+\frac{3}{4}Mg)_2+\frac{1}{2}aq$
412. BASTITE		
413. DEWEYLITE	$(\frac{1}{3}\dot{H}+\frac{2}{3}\dot{M}g)^2\dddot{S}i+\frac{2}{3}\dot{H}$	$Si\|\Theta_4\|(H_2+\frac{2}{3}Mg)_2+\frac{2}{3}aq$
414. CEROLITE	$(\frac{1}{2}\dot{H}+\frac{1}{2}\dot{M}g)\dddot{S}i+\frac{1}{2}\dot{H}$	$Si\|\Theta_4\|(\frac{1}{2}H_2+\frac{1}{2}Mg)_2+\frac{1}{2}aq$
415. HYDROPHITE	$(\frac{1}{4}\dot{H}+\frac{3}{4}(\dot{M}g,\dot{F}e))^2\dddot{S}i+\frac{3}{4}\dot{H}$	$Si\|\Theta_4\|(\frac{1}{4}H_2+\frac{3}{4}(Mg,Fe))^2+\frac{3}{4}aq$
416. GENTHITE	$(\frac{1}{4}\dot{H}+\frac{3}{4}(\dot{N}i,\dot{M}g))^2\dddot{S}i+\frac{3}{4}\dot{H}$	$Si\|\Theta_4\|(\frac{1}{4}H_2+\frac{3}{4}(Ni,Mg))_2+\frac{3}{4}aq$
417. SAPONITE		

V. KAOLINITE GROUP. Contain aluminum.

418. PHOLERITE	$\dddot{\text{Al}}^2\ddot{\text{Si}}^3+4\dot{\text{H}}$	$\text{Si}\|\Theta_4\|\beta\text{Al}_2+\frac{4}{3}\text{aq}$
419. KAOLINITE	$(\frac{1}{4}\dot{\text{H}}^3+\frac{3}{4}\dddot{\text{Al}})^2\ddot{\text{Si}}^3+\frac{3}{2}\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{4}\text{H}_2+\frac{3}{4}\beta\text{Al})_2+\frac{1}{2}\text{aq}$
420. HALLOYSITE	$(\frac{1}{4}\dot{\text{H}}^3+\frac{3}{4}\dddot{\text{Al}})^2\ddot{\text{Si}}^3+3\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{4}\text{H}_2+\frac{3}{4}\beta\text{Al})_2+\text{aq}$
421. SAMOITE		

VI. PINITE GROUP. Contain aluminum, and generally alkali metals.

422. PINITE	$(\frac{1}{4}\dot{\text{H}}^3+\frac{3}{4}(\dot{\text{K}}^3,\dddot{\text{Al}}))^2\ddot{\text{Si}}^3$	$\text{Si}\|\Theta_4\|(\frac{1}{4}\text{H}_2+\frac{3}{4}(\text{K}_2,\beta\text{Al}))_2$
423. CATASPILITE	$(\frac{3}{8}\dot{\text{R}}^3+\frac{5}{8}\dddot{\text{Al}})^2\ddot{\text{Si}}^3+\frac{3}{4}\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{3}{8}(\text{K}_2,\text{Ca},\text{Mg})+\frac{5}{8}\beta\text{Al})_2+\frac{1}{4}\text{aq}$
424. BIHARITE	$(\frac{2}{3}\dot{\text{R}}^3+\frac{1}{3}\dddot{\text{Al}})^2\ddot{\text{Si}}^3+\frac{3}{2}\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{2}{3}(\text{Mg},\text{Ca})+\frac{1}{3}\beta\text{Al})_2+\frac{1}{2}\text{aq}$
425. PALAGONITE	$(\frac{1}{4}\dot{\text{H}}^3+\frac{3}{4}(\dot{\text{R}}^3,\dddot{\text{Al}}))^2\ddot{\text{Si}}^3+n\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{4}\text{H}_2+\frac{3}{4}(\text{R},\beta(\text{Al},\text{Fe}))_2+\text{aq}$

VII. MARGARODITE GROUP. Structure micaceous. Contain aluminum, and generally alkali metals.

426. FAHLUNITE, A	$(\frac{2}{5}(\frac{1}{2}\dot{\text{H}}+\frac{1}{2}\dot{\text{R}})^3+\frac{3}{5}(\dddot{\text{Al}},\dddot{\text{Fe}}))^2\ddot{\text{Si}}^3$	$\text{Si}\|\Theta_4\|(\frac{2}{5}(\text{H}_2,\text{R})+\frac{3}{5}\beta(\text{Al},\text{Fe}))_2$
B	$(\frac{2}{5}(\frac{1}{2}\dot{\text{H}}+\frac{1}{2}\dot{\text{R}})^3+\frac{3}{5}(\dddot{\text{Al}},\dddot{\text{Fe}}))^2\ddot{\text{Si}}^3+\frac{6}{5}\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{2}{5}(\text{H}_2,\text{R})+\frac{3}{5}\beta(\text{Al},\text{Fe}))_2+\frac{2}{5}\text{aq}$
427. GROPPITE	$(\frac{1}{2}(\frac{1}{3}\dot{\text{H}}+\frac{2}{3}\dot{\text{R}})^3+\frac{1}{2}\dddot{\text{Al}})^2\ddot{\text{Si}}^3+\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{2}(\text{H}_2,\text{R})+\frac{1}{2}\beta\text{Al})_2+\frac{1}{3}\text{aq}$
428. VOIGTITE	$(\frac{1}{2}\dot{\text{R}}^3+\frac{1}{2}(\dddot{\text{Al}},\dddot{\text{Fe}}))^2\ddot{\text{Si}}^3+3\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{2}\text{R}+\frac{1}{2}\beta(\text{Al},\text{Fe}))_2+\text{aq}$
429. MARGARODITE	$(\frac{1}{3}(\frac{2}{3}\dot{\text{H}}+\frac{1}{3}\dot{\text{K}})^3+\frac{2}{3}(\dddot{\text{Al}},\dddot{\text{Fe}}))^2\ddot{\text{Si}}^3$	$\text{Si}\|\Theta_4\|(\frac{1}{3}(\text{H}_2,\text{K}_2)+\frac{2}{3}\beta(\text{Al},\text{Fe}))_2$
430. DAMOURITE	$(\frac{1}{4}(\frac{2}{3}\dot{\text{H}}+\frac{1}{3}\dot{\text{K}})^3+\frac{3}{4}(\dddot{\text{Al}},\dddot{\text{Fe}})^2\ddot{\text{Si}}^3$	$\text{Si}\|\Theta_4\|(\frac{1}{4}(\text{H}_2,\text{K}_2)+\frac{3}{4}\beta(\text{Al},\text{Fe}))_2$
431. PARAGONITE	$(\frac{1}{4}(\frac{1}{3}\dot{\text{H}}+\frac{2}{3}\dot{\text{Na}})^3+\frac{3}{4}\dddot{\text{Al}})^2\ddot{\text{Si}}^3$	$\text{Si}\|\Theta_4\|(\frac{1}{4}(\text{H}_2,\text{Na}_2)+\frac{3}{4}\beta\text{Al})_2$
432. EUPHYLLITE	$(\frac{1}{5}\dot{\text{R}}^3+\frac{4}{5}\dddot{\text{Al}})^2\ddot{\text{Si}}^3+\frac{3}{5}\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{5}(\text{K}_2,\text{Na}_2)+\frac{4}{5}\beta\text{Al})_2+\frac{1}{5}\text{aq}$
433. ŒLLACHERITE	$(\frac{1}{3}(\frac{1}{3}\dot{\text{H}}+\frac{2}{3}\dot{\text{R}})^3+\frac{2}{3}\dddot{\text{Al}})^2\ddot{\text{Si}}^3$	$\text{Si}\|\Theta_4\|(\frac{1}{3}(\text{H}_2,\text{K}_2,\text{R})+\frac{2}{3}\beta\text{Al})_2$
434. COOKEITE		

VIII. HISINGERITE GROUP. Consist largely of iron, or iron and manganese.

435. HISINGERITE	$(\frac{1}{3}\dot{\text{H}}^3+\frac{2}{3}\dddot{\text{Fe}})^2\ddot{\text{Si}}^3+4\dot{\text{H}}$	$\text{Si}\|\Theta_4\|(\frac{1}{3}(\text{H}_2,\text{R})+\frac{2}{3}\beta\text{Fe})_2+\frac{4}{3}\text{aq}$

III. SUBSILICATES.

The species here arranged as Subsilicates seem to blend indefinitely with the Unisilicates The common chlorites have atomically three-fourths, two-thirds, or less, of silica than bases, and are manifestly subsilicate in ratio. But they graduate into the pyrosclerites, which are true Unisilicates, if the water is not partly basic, and thus pass into the margarodites above. Yet the pyrosclerites have so much resemblance to the chlorites that they seem to belong to the same natural group.

Under the uncertainty with regard to the amount of basic water, the species are enumerated in the following table with their oxygen ratios, and with the constituents unarranged into formulas.

It is, however, interesting to observe that the species of pyrosclerites and chlorites may all have the formula of a two-thirds silicate if all or part of the water be made basic; and if the ratio 3 : 2 be the right one for this first section of the Subsilicates, the Subsilicates will then have the ratio 3 : 2 for the first or Chlorite group, 2 : 1 for the second or Chloritoid, and 3 : 1 for the Seybertite group. In a second table below, the formulas are written on this scheme.

I. CHLORITE GROUP. O. ratio for bases and silica, water excluded, 1 : 1 to 3 : 2.

	$\dot{R}$	$\bar{R}$	$\ddot{Si}$	$\dot{H}$	$\dot{R}\bar{R}$	$\ddot{Si}$	$\dot{H}$	
445. PYROSCLERITE	4	2	6	3	1	1	½ (¼)	$2(\frac{2}{3}\dot{M}g^3+\frac{1}{3}\bar{A}l), 3\ddot{S}i, 3\dot{H}$

I. BISILICATES.

399. TALC. Μαγνῆτις λιθος *Theophr.* Magnetis, *Germ.* Talck, Glimmer, *Agric.*, Foss., 254, Interpr., 466, 1546. Talk, Creta Brianzonia, C. Hispanica, C. Sartoria, Telgsten=Lapis Ollaris, *Wall.*, Min., 133, 134, 1747. Talcum, Tälgsten, Speckstein, Steatites, *Cronst.*, Min., 89, 75, 1758. Talc, Soapstone, Steatite, Potstone. Craie de Briançon, etc. *Fr.* Pyrallolite pt. *Nordensk.*, Schw. J., xxxi. 389, 1820. Rensselaerite *Emmons*, Rep. G. of N. Y., 1837, 152.

Orthorhombic. $I \wedge I = 120°$. Occurs rarely in hexagonal prisms and plates. Cleavage: basal, eminent. Foliated massive; sometimes in globular and stellated groups; also granular massive, coarse or fine; also compact or cryptocrystalline.

H.=1—1·5. G.=2·565—2·8. Lustre pearly. Color apple-green to white, or silvery-white; also greenish-gray and dark green; sometimes bright green perpendicular to cleavage surface, and brown and less translucent at right angles to this direction; brownish to blackish-green and reddish when impure. Streak usually white; of dark green varieties, lighter than the color. Subtransparent—subtranslucent. Sectile in a high degree. Thin laminæ flexible, but not elastic. Feel greasy. Optic-axial plane *i-ī*; bisectrix negative, normal to the base; Descl.

Var.—1. *Foliated, Talc.* Consists of folia, usually easily separated, having a greasy feel, and presenting ordinarily light green, greenish-white, and white colors. G.=2·55—2·78.

2. *Massive, Steatite* or *Soapstone* (Speckstein *Germ.*). (*a*) Coarse granular, gray, grayish-green, and brownish-gray in colors; H.=1—2·5. *Pot-stone* or *Lapis ollaris* (Topfstein) is ordinary soapstone, more or less impure. (*b*) Fine granular or cryptocrystalline, and soft enough to be used as chalk; as the *French chalk* (*Craie de Briançon*), which is milk-white, with a pearly lustre. (*c*) *Rensselaerite*, cryptocrystalline, or wax-like in composition, but often having the form and cleavage of sahlite or pyroxene, and evidently pseudomorphous; colors whitish, yellowish, grayish, greenish-white to very dark, and sometimes pearl-white; H.=3—4; G.=2·874, Beck; 2·757, fr. Grenville, 2·644, fr. Charleston Lake, in Canada, Hunt; usually translucent in pieces a fourth of an inch thick. Some agalmatolite is here included. (*d*) *Indurated talc.* An impure slaty talc, harder than ordinary talc. Talcose slate is a dark, slaty, argillaceous rock, having a somewhat greasy feel, which it owes to the presence of more or less talc.

Pyrallolite is partly pseudomorphous steatite, after pyroxene, like rensselaerite. It varies exceedingly in composition, as shown by Arppe and others, and as recognized by A. E. Nordenskiöld in his Finland Mineralogy, the silica ranging from 49 to 76 p. c. It includes pyroxene, therefore, in various stages of steatitic alteration. Three analyses are given beyond (Nos. 37–39), and others on p. 221, under pyroxene. Anal. 40 is of the same material from Finland, referred by Scheerer to his *pitkarandite.* The true pitkarandite is similar, but afforded 12·71 p. c. of $\dot{\mathrm{F}}\mathrm{e}$, and 9·17 $\dot{\mathrm{C}}\mathrm{a}$ (see anal., p. 221).

Comp.—O. ratio for $\dot{\mathrm{M}}\mathrm{g}$, $\ddot{\mathrm{Si}}$=1 : 2½, with a varying amount of water in both talc and steatite, from a fraction of a per cent. to 7 p. c. In some, the ratio for $\dot{\mathrm{M}}\mathrm{g}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 2½ : ¼, corresponding to the formula, the water being basic, $(\frac{4}{5}\dot{\mathrm{M}}\mathrm{g}+\frac{1}{5}\dot{\mathrm{H}})\ddot{\mathrm{Si}}$=Silica 62·8, magnesia 33·5, water 3·7 =100. In the larger part about 1 : 2½ : ⅓=$(\frac{4}{5}\dot{\mathrm{M}}\mathrm{g}+\frac{1}{5}\dot{\mathrm{H}})\ddot{\mathrm{Si}}+\frac{1}{15}\dot{\mathrm{H}}$=Silica 62·0, magnesia 33·1, water 4·9=100. The formula is commonly written $\dot{\mathrm{M}}\mathrm{g}^5\ddot{\mathrm{Si}}^6+2\dot{\mathrm{H}}$. The water is driven off only at a high temperature, and in some analyses that have been made it has, on this account, not been detected.

Anal. 33–36, by Lychnell, Kersten, Genth, and Senft, afford nearly the formula $\dot{\mathrm{M}}\mathrm{g}^3\ddot{\mathrm{Si}}^4$. It may be that free silica (quartz) is sometimes present, and that thence comes an occasional excess of this ingredient.

Analyses: 1, Marignac (Bibl. Univ., 1844); 2, Klaproth (Beitr., v. 60); 3, J. Schneider (J. pr. Ch., xliii. 316); 4, Hermann (J. pr. Ch., xlvi. 231); 5, 6, v. Kobell (Kastn. Arch. Nat., xii. 29); 7, Beck (Min. N. Y., 297); 8, Delesse (Rev. Scientif., etc.); 9, Wackenroder (J. pr. Ch., xxii. 8); 10, Delesse (l. c.); 11, T. S. Hunt (Rep. G. [a] After separating about 2·5 p. c. of carbonates of lime and magnesia.

In anal. 3, G.=2 763; 9, G.=2·747; 12, G.=2·69; 13, G.=2·78; 18, G.=2·79; 22, G.=2·78, 33, G.=2·795; 36, G.=2·682. For other analyses see Scheerer, Pogg., lxxxiv. 340–360.

Stromeyer found 0·4 Ṅi in the talc of Röraas, and 0·43 Ṅi in that of Sell.

The steatite from Göpfersgrün, in which Klaproth found but 59·5 per cent. of silica, along with Ṁg 30·5, Ḟe 2·3, Ḣ 5·5 (Beitr., ii. 177), is what has been called *hydrosteatite*. An impure, leek-green indurated talc, from Bristol, Ct., afforded H. H. Lummis (Am. J. Sci., II. xxxi. 368) S̈i 64·00, Ḟe 4·75, Ṁg 27·47, Ḣ 4·80=98·52. The Fenestrellos (Piedmont) pseudomorph had the cleavage of hornblende; of those of Wunsiedel (from Göpfersgrün), No. 15 was a pseudomorph after quartz, and 14 after dolomite.

Pyr., etc.—In the closed tube B.B., when intensely ignited, most varieties yield water. In the platinum forceps whitens, exfoliates, and fuses with difficulty on the thin edges to a white enamel. Moistened with cobalt solution, assumes on ignition a pale red color. Not decomposed by acids. Rensselaerite is decomposed by concentrated sulphuric acid.

Obs.—Talc or steatite is a very common mineral, and in the latter form constitutes extensive beds in some regions. It is often associated with serpentine, talcose or chloritic schist, and dolomite, and frequently contains crystals of dolomite, breunnerite, asbestus, actinolite, tourmaline, magnetite.

Steatite is the material of many pseudomorphs, among which the most common are those after pyroxene, hornblende, mica, scapolite, and spinel. The magnesian minerals are those which commonly afford steatite by alteration; while those like scapolite and nephelite, which contain soda and no magnesia, most frequently change to pinite-like pseudomorphs. There are also steatitic pseudomorphs after quartz, dolomite, topaz, chiastolite, staurolite, cyanite, garnet, idocrase, chrysolite, gehlenite.

Hunt has shown that talc (or steatite) is a rare mineral in Azoic or presilurian crystalline rocks The occurrence of rensellaerite in these rocks in northern New York is no exception, any more than pyrallolite in those of Finland, these being products of subsequent alteration or metamorphism.

Apple-green talc occurs in the Greiner mountain in Saltsburg; in the Valais, and other places above mentioned; also in Cornwall, near Lizard Point, with serpentine; in Scotland, with sea pentine, at Portsoy and elsewhere; on Unst, one of the Shetland islands; at Croky Head, Dunglow, Ireland; etc.

In N. America, foliated talc occurs in *Maine*, at Dexter. In *Vermont*, at Bridgewater, handsome green talc, with dolomite; at Athens or Grafton, Westfield, Marlboro, Newfane. In *New Hampshire*, at Francestown, Pelham, Orford, Keene, and Richmond. In *Mass.*, at Middlefield, Windsor, Blanford, Andover, and Chester. In *R. Island*, at Smithfield, delicate green, and white in a crystalline limestone. In *N. York*, near Amity; on Staten Island, near the quarantine, common and indurated; four miles distant, in detached masses made up of folia, snow-white. In *N. Jersey*, at Lockwood, Newton, and Sparta. In *Penn.*, at Texas, Nottingham, Unionville; in South Mountain, ten miles south of Carlisle; at Chestnut Hill, on the Schuylkill, talc and also soapstone, the latter quarried extensively. In *Maryland*, at Cooptown, of green, blue, and rose colors. In *N. Car.*, at Webster, Jackson Co., a variety supposed by Genth to be altered chrysolite. In *Canada*, at Potton, with steatite, in metamorphic Silurian; in the township of Elzivir, an impure grayish var. in Azoic rocks.

The so-called *rensselaerite* occurs in northern New York, in the towns of Antwerp (with the form of pyroxene), Fowler, Dekalb, Edwards (at the iron mine, a white variety, from which inkstands have been made), Russel, Gouverneur, Canton (in small crystals), Hermon (in large masses, crystalline massive); and in Canada, at Grenville, Charleston Lake, near Brockville, Rawdon, and Ramsay. It is often associated with crystalline limestone, and graduates at times imperceptibly into serpentine; its rock-masses are irregular, and are seldom continuous for more than three or four hundred yards.

Slabs of steatite are extensively employed as fire stones in furnaces and stoves. It may be turned in a lathe, or formed into tubes by boring. The fine-grained varieties (including the rensselaerite) are sometimes carved into ornaments, etc. When ground, it is used for diminishing friction. It is also employed in the manufacture of some kinds of porcelain. Venetian talc is used for removing oil stains from woollen cloth, etc.

A white steatite of a silvery-pearly lustre was the *Magnetis* of Theophrastus—a stone, according to this author, of silvery lustre, occurring in large masses, and easily cut or wrought. The word is the origin of the modern *magnesia*. Agricola, in his "Interpretatio Rerum Metallicarum" appended to his works (1546), gives as a German synonym of Magnetis, *Talck;* and he adds, as other synonyms, *Silberweiss* and *Katzensilber*, and also *Glimmer*, the German now for *mica*, evidently confounding the two minerals. He mentions its resistance to fire, and speaks of it as *lapis scissilis*.

Other later writers derive the word *talc* from the Arabic *talk;* and Aldrovandus (1648) states that it is of Moorish introduction, adding, "Hoc nomen apud Mauritanos *stellam* significare dicitur," *Stella Terræ*—Star of the Earth—being one old name of the mineral, given it because "like a star and with silvery lustre it shines." Cæsius ("De Mineralibus," 1636) writes the word in Latin, *Talchus*, but most other writers of that century, *Talcum*.

The word *steatitis* occurs in Pliny as the name of a stone resembling fat; but no further description is given that can with certainty identify it.

Rensselaerite was named after Stephen Van Rensselaer, of Albany, N. Y.

400A. TALCOID *Naumann* (Min., 5th edit., 255, 1859) is a snow-white, broadly-foliated talc of Pressnitz, described by Scheerer as *neutraler kieselsaurer Hydro-talc* (Pogg., lxxxiv. 385); G.=2·48. Analyses by Scheerer and Richter:

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{H}}$
1. Pressnitz	67·81	—	26·27	1·17	4·13=99·38 Scheerer.
2. "	67·95	0·24	25·54	1·59	4·14=99·46 Richter.

The oxygen ratio nearly 3 : 10 : 1. It may be only common talc with disseminated quartz. For another analysis of Pressnitz talc, see No. 29, above. The Kittelsthal (Thuringia) steatite (Speckstein, anal. 36, p. 453) is similar, except in the less water.

400. PYROPHYLLITE. Pyrophyllit *Herm.*, Pogg., xv. 592, 1829. Pyrauxit *Breith.*, Handb., 897, 1841. Agalmatolite or Pagodite pt.

Orthorhombic. Not observed in distinct crystals. Cleavage: basal eminent. Foliated, radiated lamellar; also granular, to compact or cryptocrystalline; the latter sometimes slaty.

H.=1–2 G.=2·75–2·92. Lustre of folia pearly, like that of talc; of massive kinds dull or glistening. Color white, apple-green, grayish and brownish-green, yellowish to ochre-yellow, grayish-white. Substransparent to opaque. Laminæ flexible, not elastic. Feel greasy. Optic-axial angle large (about 108°); bisectrix negative, normal to the cleavage-plane.

Var.—(1) Foliated, and often radiated, closely resembling talc in color, feel, lustre, and structure; G.=2·785, Berlin. (2) Compact massive, white, grayish, and greenish, somewhat resembling compact steatite, or French chalk; G.=2·81—2·92, Brush; H.=1·5—3. This compact variety, as Brush has shown, includes part of what has gone under the name of agalmatolite, from China; it is used for slate-pencils, and is sometimes called *pencil-stone*.

Comp.—O. ratio for $\ddot{\text{Al}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$, mostly, 1 : 2½ : ⅓, as for much talc, if three-fourths of the water be basic, giving the formula $(\frac{1}{5}\,\dot{\text{H}}^3+\frac{4}{5}\,\ddot{\text{Al}})\,\ddot{\text{Si}}^3+\frac{1}{5}\,\dot{\text{H}}$=Silica 65·0, alumina 29·8, water 5·2=100. The formula usually written $\ddot{\text{Al}}^2\,\ddot{\text{Si}}^5+2\,\dot{\text{H}}=\ddot{\text{Al}}^4\,\ddot{\text{Si}}^{15}+4\,\dot{\text{H}}$.

Anal. 1 and 2 give nearly the formula $\ddot{\text{Al}}\,\ddot{\text{Si}}^3+\dot{\text{H}}$=Silica 59·9, alumina 34·2, water 5·9=100; and if the specimens were not impure, they indicate that two species are here combined. The species *pyrophyllite* was established on the first of these two analyses.

Analyses: 1, Hermann (Pogg., xv. 592); 2, Igelström (B. H. Ztg., xxv. 308); 3, Rammelsberg (Pogg., lxviii. 513); 4, 5, Sjögren (Œfv. Ak. Stockh., 1848, 110); 6–8, Walmstedt (Œfv. Ak. Stockh., 1848, 111); 9, Brush (Am. J. Sci., II. xxvi. 68); 10, S. T. Tyson, 11, O. D. Allen (Am. J. Sci., II. xxxiv. 219); 12, 13, Genth (Am. J. Sci., II. xviii. 410); 14, J. L. Smith (Am. J. Sci., II. xliii. 68):

Pyr., etc.—Yields water. B.B. whitens, and fuses with difficulty on the edges. The radiated varieties exfoliate in fan-like forms, swelling up to many times the original volume of the assay. Heated with cobalt solution gives a deep blue color (alumina). Partially decomposed by sulphuric acid, and completely on fusion with alkaline carbonates.

Obs.—Compact pyrophyllite is the material or base of some schistose rocks. The foliated variety is often the gangue of cyanite.

Pyrophyllite occurs in the Urals, between Pyschminsk and Beresof; at Westana, Sweden; the Horrsjöberg in Elfdalen, with cyanite; near Ottrez in Luxembourg; in Brazil. Also in white stellate aggregations in Cottonstone Mtn., Mecklenburg Co., N. C.; in Chesterfield Dist., S. C., with lazulite and cyanite; in Lincoln Co., Ga., on Graves Mtn.; in Arkansas, at the Kellogg lead mine, near Little Rock. The compact kind, resembling a slaty soapstone in aspect and feel, is found in large beds at Deep River, N. C., greenish to yellowish-white in color, with G.=2·91; similar at Carbonton, Moore Co., N. C., having G.=2·82.

The compact pyrophyllite of Deep River, N. C., is extensively used for making slate pencils.

Thomson, in an analysis of his *nacrite* (Rec. Gen. Sci., iii. 332) from "Brunswick" (should have been *Unity*), Maine, obtained the composition of a pyrophyllite. But the mineral is actually a green mica; the high silica, *as he says*, was due to mixed quartz.

401. PIHLITE. Pihlit *Sefström*, Svanberg, Ak. H. Stockh., 1839, 155. Cumatolite *C. U. Shepard*, private publication, May 24, 1867. Cymatolite *id.*, Correspondence, Dec. 24, 1867.

Micaceous. Sometimes constituting long prisms, but only as a pseudomorph. Surface of plates sometimes wavy.

H.=1·5. G.=2·72, pihlite, Svanberg; 2·74, cymatolite, Shepard. Lustre pearly, or satin-like. Color white, almost silvery; also yellowish. Laminæ brittle, but separating into thin scales, which are flexible, somewhat elastic and transparent. Feel soft.

Comp.—$(\dot{\mathrm{R}}^3, \dddot{\bar{\mathrm{A}}}\mathrm{l})\dddot{\mathrm{Si}}^3$, from Svanberg's analysis, if the water be basic; from Burton's, if half of the water be basic, $(\frac{1}{3}(\frac{1}{2}\dot{\mathrm{H}}+\frac{1}{2}\dot{\mathrm{K}})+\frac{2}{3}\dddot{\bar{\mathrm{A}}}\mathrm{l})\dddot{\mathrm{Si}}^3$. It is closely related to pyrophyllite, but is unlike that species in its appearance and its alkalies. **Analyses:** 1, Svanberg (l. c.); 2, 3, B. S. Burton (priv. contrib.):

	$\dddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{L}}\mathrm{i}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1. Brattstad	63·68	25·12	3·01	1·52	——	——	——	3·76	2·39, F 0·84, Mg 0·58=100·89 Sv.
2. Goshen	61·21	28·01	——	——	0·43	0·53	0·57	4·54	3·83=99·12 Burton.
3. "	61·20	27·27	——	——	*undetermined*				3·78 Burton.

Prof. Shepard, in an imperfect examination (priv. contrib.), obtained $\dddot{\mathrm{Si}}$ 59·4, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 33·91, $\dot{\mathrm{F}}\mathrm{e}$ with $\dot{\mathrm{M}}\mathrm{n}$ 2·50, $\dot{\mathrm{H}}$ 1·40=97·21.

Pyr., etc.—In a closed tube yields water at a high temperature (Brush). B.B. fuses at 6, or only on the thinnest edges; infusible (Svanberg). Scarcely attacked by acids.

Obs.—From Brattstad, near Sala, Sweden, in granite. Also (cymatolite) from the indicolite locality, Goshen, Mass., and from Norwich; at both places covering crystals of spodumene, sometimes at the latter to a depth of three-fourths of an inch; and also as continuations of spodumene crystals, the foliation, according to Shepard, at right angles to the spodumene; appears to be a result of the alteration of the spodumene.

Named after the Swedish mining director, Pihl. *Cymatolite* is from κῦμα, *wave*.

402. SEPIOLITE. Meerschaum *Germ.*, Wern. Bergm. J., 377, 1788. L'Ecume de Mer *Fr.* Keffekill *Kirw.*, i. 144, 1794. Magnesite pt. *Brongn.*, Min., 1807; Magnesite *id.*, 1824. Sepiolith *Glock.*, Syn., 190, 1847.

Compact, with a smooth feel, and fine earthy texture, or clay-like.

H.=2—2·5. Impressible by the nail. In dry masses floats on water. Color grayish-white, white, or with a faint yellowish or reddish tinge. Opaque.

Comp.—O ratio for $\dot{\mathrm{R}}, \dddot{\mathrm{Si}}, \dot{\mathrm{H}}=1:3:1$, corresponding to $\dot{\mathrm{M}}\mathrm{g}^2\dddot{\mathrm{Si}}^3+2\dot{\mathrm{H}}$; or, if half the water is basic, $1:2:\frac{1}{3}=(\frac{2}{3}\dot{\mathrm{M}}\mathrm{g}+\frac{1}{3}\dot{\mathrm{H}})\dddot{\mathrm{Si}}+\frac{1}{3}\dot{\mathrm{H}}$=Silica 60·8, magnesia 27·1, water 12·1=100. **Analyses:** 1, Lychnell (Ak. H. Stockholm, 1826, 175); 3, Schultz (Ramm. Min. Ch., 1000); 2, 4–8, Scheerer & Richter (Pogg., lxxxiv. 361); 9, Damour (Ann. Ch. Phys., III. vii. 316):

	$\dddot{\mathrm{Si}}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{H}}$
1. Asia Minor	60·87	27·80	11·29, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ and $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 0·09=100·05 Lychnell.

9. Morocco	55·00	28·00	10·35, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 1·40, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 1·20, $\dot{\mathrm{C}}\mathrm{a}$ 1·01, $\dot{\mathrm{K}}$ 0·52, sand 1·50=98·98 Dam.

19 to 20 per cent. of water were found by Berthier in meerschaum from Madrid and Coulommiers (Ann. d. M., vii. 313); and by von Kobell in that of Greece (J. pr. Ch., xxviii. 482); as follows:

	$\dddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{H}}$
1. Spain	53·8	1·2	23·8	20·0=98·8 Berthier.
2. Coulommiers	54·0	1·4	24·0	20·0=99·4 "
3. Greece	48·0	*tr.*	20·06	19·6, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 12·40=100·06 Kobell.

Döbereiner also found two atoms of water (instead of 1) in the meerschaum of Asia Minor. Klaproth (Beitr., ii. 172) found in the same 5 per cent. of carbonic acid, which proceeded from intermixed carbonate of magnesia.

A related mineral, found in the serpentine of Zöblitz, a little translucent, white or yellowish, with H.=2·335, afforded Delesse $\dddot{\mathrm{Si}}$ 53·5, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 0·9, with $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ *tr.*, $\dot{\mathrm{M}}\mathrm{g}$ 28·6, $\dot{\mathrm{H}}$ 16·4=99·4.

Pyr., etc.—In the closed tube yields first hygroscopic moisture, and at a higher temperature gives much water and a burnt smell. B.B. some varieties blacken, then burn white, and fuse with difficulty on the thin edges. With cobalt solution a pink color on ignition. Decomposed by muriatic acid with gelatinization.

Obs.—Occurs in Asia Minor, in masses in stratified earthy or alluvial deposits at the plains of Eskihi-sher, where, according to Dr. J. Lawrence Smith, it has proceeded from the decomposition of carbonate of magnesia, which is imbedded in serpentine in the surrounding mountains. He observes that more or less carbonate of magnesia is often found in the meerschaum (Am. J. Sci., II. vii. 286); also found in Greece; at Hrubschitz in Moravia; in Morocco; at Vallecas in Spain, in extensive beds, affording a light but valuable building stone. The mineral from Morocco, called in French *Pierre de savon de Maroc*, is used in place of soap at the Moorish baths in different places in Algeria.

The word *meerschaum* is German for *sea-froth*, and alludes to its lightness and color. *Sepiolite* Glocker, is from *σηπια*, *cuttle-fish*, the bone of which is light and porous; and being also a production of the sea, "deinde *spumam marinam* significabat," says Glocker.

Brongniart, in the first edition of his Mineralogy (1807), included under *Magnesite* (1) the carbonate, which he calls *Mitchell's magnesite* (see under MAGNESITE); (2) the hydrous silicate or meerschaum; and (3) the siliceous carbonate from Baudissero in Piedmont; he putting "Mitchell's magnesite," the carbonate, *first*. Karsten, in his "Tabellen," published the next year, separated from meerschaum the carbonate, and adopted for it the name *magnesite*, and in this he has been followed by all German and most other mineralogists. The application of the name *magnesite* to the hydrous silicate, done in the later writings of Brongniart and by subsequent French mineralogists, is hence in violation of the law of priority.

403. APHRODITE. Aphrodit *Berlin*, Ak. H. Stockh., 172, 1840.

Soft and earthy like sepiolite.
G.=2·21. Color milk-white. Opaque.

Comp.—O. ratio for $\dot{\text{R}}$, $\dddot{\text{Si}}$, $\dot{\bar{\text{H}}}=1:2:\frac{3}{4}$; $\dot{\text{Mg}}\dddot{\text{Si}}+\frac{3}{4}\dot{\bar{\text{H}}}$. Berlin obtained (l. c.) Silica 51·55 magnesia 33·72, protoxyd of manganese 1·62, protoxyd of iron 0·59, alumina 0·20, water 13·82.

Obs.—From Longban, Sweden.

Named from *ἀφρός*, *foam*.

Delesse has analyzed another species, containing Silica 53·5, magnesia 28·6, alumina with trace of sesquioxyd of iron 0·9, water 16·4=nearly $\dot{\text{Mg}}\dddot{\text{Si}}+\dot{\bar{\text{H}}}$. Occurs in serpentine, of a white or yellowish color, with a waxy lustre, and somewhat translucent. G.=2·385.

Hampshirite is a name applied by Hermann to the steatite of certain steatitic pseudomorphs described and analyzed by Dewey (Am. J. Sci., iv. 274, v. 249, vi. 334, 1822, 1823), who obtained $\dddot{\text{Si}}$ 50·60, $\dddot{\bar{\text{Al}}}$ 0·15, $\dot{\text{Mg}}$ 28·83, $\dot{\text{Fe}}$ 2·59, $\dot{\text{Mn}}$ 1·10, $\dot{\bar{\text{H}}}$ 15·00. It gives the oxygen ratio for $\dot{\text{R}}$, $\dddot{\text{Si}}$, $\dot{\bar{\text{H}}}$, 1 : 2 : 1. But the constituents of pseudomorphs are seldom pure species, and without thorough investigation afford no sufficient ground for instituting a new species. They have mostly the form of quartz.

404. CIMOLITE. Κιμωλία *Theophr.* Cimolia *Plin.*, xxxv. 57. Cimolit *Klapr.*, Beitr., i 291, 1795. Pelikanit *Ouchakoff*, Bull. St. Pet., xvi. p. 129, J. pr. Ch., lxxiv. 254. Hunterite *Haughton*, Phil. Mag., IV. xvii. 18, 1859, xxiii. 50.

Terra Lemnia *Dioscor*, *Plin.*, etc. Sphragid *Karst.*, Tab., 28, 88, 1808. Ehrenbergit *Nöggerath*, Verh. nat. Ver. Bonn, ix. 378, 1852.

Amorphous, clay-like, or chalky.

Very soft. G.=2·18—2·30. Lustre of streak greasy. Color white, grayish-white, reddish. Opaque. Harsh. Adheres to the tongue.

Comp.—O. ratio for $\dddot{\bar{\text{Al}}}$, $\dddot{\text{Si}}$, $\dot{\bar{\text{H}}}=1:3:1$; corresponding to $\dddot{\bar{\text{Al}}}^{2}\dddot{\text{Si}}^{9}+3\dot{\bar{\text{H}}}$; or, if half of the water is basic, $(\frac{1}{3}\dddot{\bar{\text{Al}}}+\frac{1}{3}\dot{\bar{\text{H}}}^{3})\dddot{\text{Si}}^{3}+\dot{\bar{\text{H}}}$. Analyses: 1, Klaproth (l. c.); 2, Ilimoff (Ann. J. M. Russ., 1841, 336); 3, v. Hauer (Jahrb. geol. Reichs., 1854, 67); 4, Ouchakoff (l. c.); 5, Haughton (l. c.):

	$\dddot{\text{Si}}$	$\dddot{\bar{\text{Al}}}$	$\dddot{\bar{\text{Fe}}}$	$\dot{\bar{\text{H}}}$
1. Argentiera	63·00	23·00	1·25	12·00=99·25 Klaproth.
2. Ekaterinovska	63·52	23·55	—	12·00=99·07 Ilimoff.
3. Near Bilin	62·30	24·28	—	12·34, $\dot{\text{Ca}}$ 0·83=99·70 Hauer. G.=2·376.
4. Kiew, *Pelicanite*	65·66	22·84	0·44	9·31, $\dot{\text{Mg}}$ 0·56, $\dot{\text{K}}$ 0·30, $\dot{\text{P}}$ 0·17=99·28 Ouchakoff
5. *Hunterite*	65·93	20·97	—	11·61, $\dot{\text{Mg}}$ 0·45, $\dot{\text{Ca}}$ 0·30=99·26 Haughton.

Klaproth, in a later analysis (Beitr., vi. 2-8), obtained $\dddot{\mathrm{Si}}$ 54·0, $\dddot{\bar{\mathrm{Al}}}$ 26·5, $\bar{\mathrm{Fe}}$ 1·5, $\dot{\mathrm{K}}$ 5·5, $\dot{\mathrm{H}}$ 12. The huntorite, according to the analysis, contains a little excess of silica, probably due to free quartz, as the material was gritty under the pestle.

Pyr., etc.—Yields water. B.B. becomes gray and finally burns white; infusible. With cobalt solution a blue color.

Obs.—From the island of Argentiera (Κιμωλή of the Greeks); Berg Hradischt, near Bilin, Bohemia; also from Ekaterinovska, district of Alexandrovsk, Russia; Government of Kiev, Russia; Nagpur, Central India, with orthoclase in granite.

404A. SPHRAGIDITE. (Λημνία γῆ *Dioscor.* Σφραγὶς λήμνια. Terra Lemnia *Plin.*, xxxvi. Sphragid *Karst.*, Tab., 28, 88, 1808.) Related in composition to cimolite, but contains some alkali. Color yellowish-gray, brownish, or yellowish-white. Sometimes mottled with rust-like spots; harsh to the touch, adheres feebly to the tongue, and forms a paste with water.

Klaproth obtained for its composition (Beitr., iv. 333):

$\dddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
66·00	14·50	6·00	0·25	0·25	3·50	8·50

From Stalimene, the ancient *Lemnos.* It was also called *Terra sigillata.* It was dug for medicinal purposes once a year, cut into spindle-shaped pieces, and *stamped with a seal*, and hence the name *sigillata* in Latin, and *sphragis* in Greek. There was also a *Rubrica Lemnia*, or *Lemnian Reddle*, used by painters, which is confounded by Pliny with the true terra lemnia.

404B. EHRENBERGITE *Nöggerath* (Verh. nat. Ver. Bonn, ix. 378, 1857). Near the preceding in composition, and, like that, containing alkali. It is almost gelatinous in the fresh state, and becomes fragile, pulverulent, and opaque on drying; color rose-red. Analyses: 1, Schnabel (l. c.); 2, G. Bischof (l. c.):

	$\dddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$, $\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$	
1.	56·77	15·77	1·65	0·86	1·30	2·76	3·78	17·11=100	Schnabel.
2.	64·54	6·04	4·56	4·61	0·41	3·96	8·11	7·77=100	Bischof.

Ehrenbergite occurs in clefts in trachyte at the quarries of Steinchen and Wolkenburg, Siebengebirge.

400C. ANAUXITE *Breith.* (J. pr. Ch., xv. 325, 1838). Greenish-white, pearly, granular; with cleavage in one direction. Translucent. H.=2—2·5. G.=2·26. Plattner obtained (l. c.) $\dddot{\mathrm{Si}}$ 55·7, $\dot{\mathrm{H}}$ 11·5, with much $\dddot{\bar{\mathrm{Al}}}$, a little $\dot{\mathrm{Mg}}$ and $\dot{\mathrm{Fe}}$.

From Bilin, Bohemia.

404D. PORTITE *Meneghini & Bechi* (Am. J. Sci., II. xiv. 63). Orthorhombic. In radiated masses; cleavage very distinct parallel to a rhombic prism of 120°. H.=5. G.=2·4. Lustre vitreous. Color white. Opaque.

Comp.—If the protoxyds are not an essential part of the compound, the mineral corresponds to the formula $\dddot{\bar{\mathrm{Al}}}\,\dddot{\mathrm{Si}}^3+2\,\dot{\mathrm{H}}$. Analysis by Bechi (Am. J. Sci., II. xiv. 63):

$\dddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
58·12	27·50	4·87	1·76	0·16	0·10	7·92=100·43.

Yields water. B.B. intumesces much and affords a milk-white enamel. Dissolves in acids, even in the cold, and gelatinizes. From the gabbro rosso in Tuscany. Named after Mr. Porte of Tuscany.

405. SMECTITE. Fuller's Earth pt.; Terra *or* Creta Fullonum pt.; Walkthon, Walkerde pt., *Germ.*; Terre à Foulon pt. *Fr.* Smectit *Breith.*, Handb., 344, 1841. Malthacit *Breith.*, J. pr. Ch., x. 510, 1837.

Massive. Clay-like.

Very soft. G.=1·9—2·1. Lustre dull; of streak shining. Color white, gray, and various shades of green to mountain-green and olive-green, or brownish. Streak colorless. Unctuous. Does not adhere to the tongue. Softens in water.

Var.—*Fuller's Earth* includes many kinds of unctuous clays, gray to dark-green in color, and is only in part Breithaupt's smectite. Much of it is kaolinite. *Malthacite* is described as occurring in thin laminæ or scales, and sometimes massive, with the color white or slightly yellowish, and thin plates translucent; the original is from basalt, at Steindörfel, in Lausitz; and Beraun in Bohemia is given as another locality. *Smectite* is a mountain-green, oil-green, and grayish-green clay, from Cilley in Lower Styria.

Comp.—O. ratio for $\dddot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$ = 1 : 4 : 4 in anal. 1; whence, if a fourth of the water is basic, $(\frac{1}{2}\dddot{\mathrm{Al}}+\frac{1}{2}\dot{\mathrm{H}}^3)\ddot{\mathrm{Si}}^3+4\frac{1}{2}\dot{\mathrm{H}}$.

The chemical species characteristic of these minerals is probably the same—a silicate of alumina related to cimolite, but containing three or four times as much water.

Analyses: 1, Jordan (Pogg., lxxvii. 591); 2, Klaproth (Beitr., iv. 338); 3, O. Meissner (l. c):

	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dddot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
1. Cilley, *Smectite*	51·21	12·25	2·07	4·89	2·13	27·89=100·44 Jordan.
2. Reigate, *Fuller's E.*	53·00	10·00	9·75	1·25	0·50	24·00, $\dot{\mathrm{K}}$ *tr.*, Na Cl 0·10=98·60 Klapr.
3. Steindörfel, *Malth.*	50·17	10·66	3·15	——	0·25	35·83=100·06 Meissner.

Pyr., etc.—B.B. the malthacite is infusible; but the smectite and the Reigate fuller's earth, owing to the impurities present, fuse rather easily. Decomposed by muriatic acid.

Obs.—All the kinds have a soapy feel.

RHODALITE *Thomson* (Min., i. 354, 1836) is a rose-red mineral, "seeming to consist of a congeries of small rectangular prisms with square bases." Earthy; feel soapy; H.=2·0; G.=2·0. Easily scratched and polished with the nail. B.B. not altered.

Composition, according to Richardson (l. c.), $\ddot{\mathrm{Si}}$ 55·9, $\dddot{\mathrm{Al}}$ 8·3, $\dddot{\mathrm{Fe}}$ 11·4, $\dddot{\mathrm{Mn}}$ *tr.*, $\dot{\mathrm{Mg}}$ 0·6, $\dot{\mathrm{Ca}}$ 1·1, $\dot{\mathrm{H}}$ 22·0 =99·3. From nodules in amygdaloid, in Antrim, northern Ireland. "It appeared to have been partially acted upon by the rain and weather." Portlock states that the mineral contains less iron than Thomson's analysis gives, and also that it readily fuses.

406. MONTMORILLONITE. *Salvetat*, Ann. Ch. Phys., III. xxi. 376, 1847. Confolensite *Dufr.*, Min., iii. 583, 1856. Delanovit *Kenng.*, Jahrb. G. Reichs., iv. 633, 1853. Delanouite *Dufr.*, Min., iii. 583, 1856. Stolpenit (=Bole of Stolpen) *Kenng.*, Min., 41, 1853. Saponite *Nicklès*, Ann. Ch. Phys, III. lvi. 46, 1859=Pierre a savon (*Germ.* Bergseife) de Plombières. Steargillite *Meillet*, Descl. Min., i 205, 1862. Erinite *Thomson*, Min., i. 341, 1836.

Massive, clay-like.

Very soft and tender. Lustre feeble. Color white or grayish to rose-red, and bluish; also pistachio-green. Softens in water, and for the most part does not adhere to the tongue. Unctuous.

Var.—(1) *Montmorillonite* is rose-red; from Montmorillon, France. *Confolensite* is paler rose-red; fr. Confolens, Dept. of Charente, at St. Jean-de-Côle, near Thiviers. *Delanouite* is similar in color, and is fr. Millac, near Nontron, France; stated by Kenngott to adhere to the tongue.

(2) *Stolpenite* is a clay from the basalt of Stolpen. *Steargillite* is white, yellow, and pistachio-green, subtranslucent, insoluble in acids; and is easily cut into cakes looking like soap or wax; fr. near Virolet on the Rochelle railroad, and at the tunnel of Poitiers. *Saponite* of Nicklès is a soap-like clay from the granite from which issues one of the hot springs of Plombières, France, called *Soap Spring*.

Erinite is a yellowish-red clayey mineral from the Giant's Causeway; G.=2·04; opaque; a little resinous in lustre; unctuous; B.B. infusible but whitens. Named from Erin (Ireland).

Comp.—Like smectite, but containing more alumina. O. ratio for $\dddot{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : $2\frac{1}{2}$: $2\frac{1}{3}$; whence $(\frac{4}{5}\dddot{\mathrm{Al}}+\frac{1}{5}\dot{\mathrm{H}}^3)\ddot{\mathrm{Si}}^3+5\dot{\mathrm{H}}$. Analyses: 1, 2, Salvetat and Damour (l. c.); 3, Berthier (Tr. d. Ess. v. sèche, i. 58); 4. v. Hauer (Jahrb. G. Reichs., iv. 683) 5, 6, Salvetat (Ann. Ch. Phys., III. xxxi. 120); 7, Rammelsberg (Pogg., xlvii. 180); 8, Meillet (l. c.); 9, Nicklès (l. c.); 10, Berthier; 11, Thomson (l. c.):

		$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dddot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$,K	$\dot{\mathrm{H}}$

11. *Erinite*	47·04	18·46	6·36	——	$\dot{Ca}$ 1·00	——	25·28, Na Cl 0·9=99·04 T

Salvetat observes that carbonate of soda separates a little gelatinous silica, and sulphuric acid some quartz-silica—a fact of great interest in connection with the earthy hydrous aluminous silicates generally.

Pyr., etc.—B.B. infusible, excepting the stolpenite, which affords a yellowish enamel, probably owing to the 4 p. c. of lime in the state of silicate present as impurity. Montmorillonite loses 6 p. c. of water at 100° C., and delanouite 14 p. c. The *saponite* lost, according to Nicklès, 22 p. c. of water in dry air at 15° C.; 34·5 p. c. at 100° C.; and 37 p. c. at redness. The loss over sulphuric acid was 29 p. c.

Severite, according to the analysis of Pelletier (p. 477), would be identical nearly with the mineral from Confolens.

406A. *Razoumoffskin* of John, a greenish-white clay-like mineral from Kosemütz, in Silesia, is near montmorillonite, except in the less amount of water. Zellner obtained:

$\ddot{Si}$ 54·50 $\bar{Al}$ 27·25 $\dot{Fe}$ 0·25 $\dot{Mg}$ 0·37 $\dot{Ca}$ 2·00 $\dot{H}$ 14·25=98·62.

A *lithomarge* (Steinmark) from Strimbuly, Transylvania, afforded Hingenau (Jahrb. Min., 1856 690):

$\ddot{Si}$ 52·40 $\bar{Al}$ 21·80 $\dot{Mg}$ 4·28 $\dot{Ca}$ 2·50 $\dot{K}$, $\dot{Na}$ 1·34 $\dot{H}$ [17·68]=100.

It is, probably, judging from the magnesia and alkalies present, only a mixture.

407. STILPNOMELANE. *Glocker*, ZS. f. Min., Jan., 1828, Handb., 572, 1831. Chalcodite *Shep.*, Rep. Am. Assoc., vi. 232, 1851.

Foliated plates, sometimes hexagonal, sometimes radiated. Also fibrous, or as a velvety coating even or tufted. Cleavage easy in one direction.

H.=3—4, when in solid plates. G.=3—3·4, Glocker; 2·769, Breith.; 2·76, chalcodite, Brush. Lustre of cleavage surface between pearly and vitreous, sometimes submetallic or brass-like. Color black, greenish-black, yellowish-bronze, and greenish-bronze.

Var.—(1) *Ordinary*, in plates or massive.

(2) *Chalcodite*, in velvety coatings of brass-like or submetallic lustre, consisting of minute scales, which are flexible.

Comp.—O. ratio for $\dot{R}+\bar{R}$, $\ddot{Si}$, $\dot{H}$=3 : 6 : 2 nearly, from anal. 1 to 3; whence $(\dot{R}^3, \bar{R})\ddot{Si}^2+2\dot{H}$. Brush's analysis, in which the state of oxydation of the iron was determined, gives 13·39 : 24·15 : 8·18, or nearly the same.

Analyses: 1, Rammelsberg (Pogg., xliii. 127); 2, Siegert (Ramm., 5th Suppl., 280, Min. Ch., 880); 3, L. J. Igelström (J. pr. Ch., lxxxi. 396); 4, G. J. Brush (Am. J. Sci., II. xxv. 198):

		$\ddot{Si}$	$\bar{Al}$	$\bar{Fe}$	$\dot{Fe}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{K}$	$\dot{H}$
1. Obergrund	(4/4)	45·96	5·84	——	35·60	1·78	0·19	0·75	8·63=98·75 Ramm.
2. Weilburg		45·07	4·92	41·98	——	0·94	1·67	——	8·47=98·85 Siegert.
3. Nordmark		45·61	5·00	37·70		3·00	——	——	9·14=100·45 Igelström
4. *Chalcodite*	(2/3)	45·29	3·62	20·47	16·47	4·56	0·28	*tr.*	9·22=99·91 Brush.

Brush ascertained the identity of chalcodite with stilpnomelane; Mallet analyzed it (Am. J. Sci., II. xxiv. 118), but, as he states, he had too little of the mineral for reliable results.

Pyr., etc.—Yields much water. B.B. fuses easily to a black, shining, magnetic globule. With the fluxes gives the reactions for iron. Chalcodite is completely decomposed by muriatic acid.

Obs.—Stilpnomelane occurs at Obergrund and elsewhere in Silesia, with calcite and quartz, sometimes intermixed with pyrite and magnetite. Also in Moravia, near Brokersdorf; near Sternberg, in a bed of limonite, in a clay slate, probably of the Devonian age, and often associated with chlorite, magnetite, and calcite; at Frederic mine near Weilburg, Nassau, in a bed of iron ore; at

Pen Mine, Nordmark, Sweden, radiated foliated with actinolite, in veins sometimes 4 inches thick Chalcodite occurs at the Sterling Iron mine, in Antwerp, Jefferson Co., N. Y., coating hematite and calcite, and sometimes constituting pseudomorphs, having the form of hollow rectangular tables the yellow variety resembles in color mosaic gold.

Named *Stilpnomelane* from στιλπνός, *shining*, and μέλας, *black*; and *Chalcodite*, from χαλκός, *brass* or *bronze*.

408. CHLOROPAL. *Bernhardi & Brandes*, Schw. J., xxxv., 29, 1822. Unghwarit *Glocker* Grundr., 1839, 537. Nontronite *Berthier*, Ann. Ch. Phys., xxxvi. 22, 1827. Pinguite *Breith.*, Schw. J., lv 303, 1829. Fettbol *Freiesleben*, Mag. Orykt. Sachsen, v. 136. Graminite *Krantz*, Ges. Nat. Heil-kunde, Bonn, March, 1857, C. Bergemann, Jahrb. Min., 1857, 395.

Compact massive, with an opal-like appearance; earthy.

H.=2·5–4·5. G.=1·727, 1·870, earthy varieties, the second a conchoidal specimen; 2·105, Thomson, a Ceylon chloropal. Color greenish-yellow and pistachio-green. Opaque—subtranslucent. Fragile. Fracture conchoidal and splintery to earthy. Feebly adhering to the tongue, and meagre to the touch.

Var.—*Chloropal* has the above-mentioned characters, and was named from the Hungarian mineral occurring at Unghwar, whence Glocker's name Unghwarite. It is described as breaking into parallelopipeds, having opposite magnetic polarity at opposite angles.

Nontronite is pale straw-yellow or canary-yellow, and greenish, with an unctuous feel; flattens and grows lumpy under the pestle, and is polished by friction; from Nontron, Dept. of Dordogne, France.

Pinguite is siskin and oil-green, extremely soft, like new-made soap, with a slightly resinous lustre, not adhering to the tongue; the original from Wolkenstein in Saxony.

Fettbol has a liver-brown color, a slightly greasy lustre, shining streak, conchoidal fracture, and G.=2·249, Breith., and is from Halsbrücke near Freiberg.

Graminite has a grass-green color (whence the name), and occurs at Menzenberg, in the Siebengebirge, in thin fibrous seams, or as a feather of delicate lamellæ; H.=1; G.=1·87, after drying at 212° F.; lustre and feel somewhat greasy, as in pinguite.

Comp.—A hydrated silicate of iron, with probably the general formula $\bar{\text{Fe}}\,\ddot{\text{Si}}^3+4\tfrac{1}{2}\,\dot{\text{H}}$=Silica 42·7, sesquioxyd of iron 38·0, water 19·3=100; or $(\dot{\text{Fe}}^3, \bar{\text{Fe}})\,\ddot{\text{Si}}^3+4\tfrac{1}{2}\,\dot{\text{H}}$. The water and silica both vary much. The Hungarian chloropal occurs mixed with opal, and graduates into it, and this accounts for the high silica of some of its analyses.

Analyses: 1, 2, Bernhardi & Brandes (l. c.); 3, 4, Hiller (Jahresb., 1857, 671); 5, Thomson (Min., i. 464); 6, v. Hauer (Ber. Ak. Wien, xii. 161, 1854); 7, Berthier (Ann. Ch. Phys., xxxv. 92); 8, Dufrénoy (Ann. d. M., III. iii. 393); 9, Jacquelin (Ann. Ch. Phys., xlvi. 101); 10, Biewend (J. pr. Ch., xi. 162); 11, 12, Mehner (J. pr. Ch., xlix. 382); 13, H. Müller, 14, E. Uricoechea (this Min., 1854, 337); 15, Kersten (Schw. J., lxvi. 9); 16, Bergemann (l. c.); 17, Kersten (Schw. J., lxvi. 31):

[a] With some potash.

Kobell found, after expelling the water (J. pr. Chem., xliv. 95):

1. Haar	$\ddot{\rm Si}$ 52·10	$\dddot{\rm Fe}$ 40·60	$\dddot{\rm Al}$ 8·00	$\dot{\rm Ca}$ 1·60	$\dot{\rm Mg}$ 1·08=98·38.
2. Hungary	52·33	43·34	2·32	0·93	0·73=99·65.

This chemist regards the chloropal as a mixture of $\dddot{\rm Fe}\ \ddot{\rm Si}^3+2\ \dot{\rm H}$ and *opal;* and he writes the same formula for nontronite and pinguite.

Pyr., etc.—Yields water. B.B. infusible, but turns black and becomes magnetic. With the fluxes gives reactions for iron. Chloropal is partially decomposed by muriatic acid; pinguite is completely decomposed, with separation of pulverulent silica, while nontronite gelatinizes with muriatic acid.

Obs.—Localities are mentioned above. The locality of *chloropal* at Meenser Steinberg (anal. 3 is near Göttingen; *pinguite* occurs also at Sternberg in Moravia.

Named from χλωρός, *green*, and *opal*.

Chloropal also occurs (Church, Chem. News, 1866, ii. 71) in a china-stone quarry, near the old tin mine known as Carclase, not far from St. Austell, in Cornwall, associated with fluor; it is the variety which has been named *graminite.*

409. GLAUCONITE. Glaukonit *Keferstein*, Deutsch. geol. dargest., v. 510, 1828, *Glocker*, Handb., 832, 1831. Grünerde pt. *Germ.* Green Earth pt. Terre verte pt. *Fr.* Chlorophänerit *Jenzsch*, Jahrb. Min., 798, 1855.

Amorphous, and resembling earthy chlorite. Either in cavities in rocks, or loosely granular massive.

H.=2. G.=2·2—2·4. Lustre dull, or glistening. Color olive-green, blackish-green, yellowish-green, grayish-green. Opaque.

Comp., Var.—Essentially a hydrous silicate of iron and potash; but the material is mostly, if not always, a mixture, and consequently varies much in composition. In most of the analyses the state of oxydation of the iron was not determined. Haushofer, who examined this point, gives as the most common oxygen ratio for $\dot{\rm R}$, $\dddot{\rm R}$, $\ddot{\rm Si}$, $\dot{\rm H}$, 1 : 3 : 9 : 3, and writes the formula $\dot{\rm R}\ \ddot{\rm Si}+\dddot{\rm R}\ \ddot{\rm Si}^2+3\ \dot{\rm H}$=(if $\dot{\rm R}=\frac{1}{2}\dot{\rm Fe}+\frac{1}{2}\dot{\rm K}$, and $\dddot{\rm R}=\frac{4}{5}\dddot{\rm Fe}+\frac{1}{5}\dddot{\rm Al}$) Silica 49·3, alumina 3·6, sesquioxyd of iron 22·7, protoxyd of iron 6·3, potash 8·3, water 9·6. The ratio is that of a hornblende, and especially acmite, excepting the water and the presence of potash in place of soda, this ratio between the bases and silica being 1 : 2½. Differs from celadonite in being decomposed by muriatic acid.

The kinds of glauconite are:

1. Green earth of cavities in eruptive rocks: to which the *chlorophanerite* of G. Jensch may perhaps be added.

2. Green grains of sand beds or rocks, as of the green sand of the chalk formation, rarely found in limestones; called *glauconite* (in allusion to the green color). H.=2; G.=2·29—2·35; color olive-green to yellowish-green.

Analyses: 1, Delesse (Bib. Univ. Gen. 1848, June, 106); 2, 3, Waltershausen (Vulk. Gest., 301); 4, G Jenzsch (l. c.); 5, S. L. Dana (Hitchcock's G. R. Mass., 98, 1841); 6–8, Rogers (G. Rep N. J., 201–204); 9, Fisher (Am. J. Sci., II. ix. 83); 10, Berthier (Ann. d. M., xiii.); 11, D. H. von Dechen (Verh. nat. Ver. Bonn, 1855, 176); 12, W. van der Marck (ib., 1855, 263); 13–15 Mallet (Am. J. Sci., II. xxiii. 181); 16–18, T. S. Hunt (Rep. G. Can., 1863, 486–488); 19, 20 Berthier; 21–27, Haushofer (J. pr. Ch., xcvii. 353); 28, id. (ib., cii. 38); 29, H. Wurtz (Am. J Sci., II. x. 326):

[a] 11·85 p. c. of Si O² insol. in carb. soda. [b] 28·89 p. c. of Si O² insol. in carb. soda.

Anal. 3, G.=2·166; 13, G.=2·297; 15, G.=2·349; 16, 17, fr. Lower Silurian rocks of the Quebec Group; 18, fr. Lower Magnesian Limestone, Lower Silurian; 21–25, 28, 29, Cretaceous; 26, Jurassic; 27, Triassic (Muschelkalk). In 29, 4·81 out of the 11·50 Ḣ called hygroscopic.

Pyr., etc.—Yields water. Fuses easily to a dark magnetic glass. Some varieties are entirely decomposed by muriatic acid, while others are not appreciably attacked.

A green calcite from Central India contains a skeleton of glauconite—separable by acids—constituting about 14 p. c. of the whole, which afforded S. Haughton, on analysis (Phil Mag., IV. xvii. 6), S̈i 54·59, A̶l 4·74, Ḟe 22·84, Ṁg 4·90, Ċa 0·94, Ḣ and loss 11·99. He names the rock, which is a mixture of calcite and glauconite, *Hislopite.* An analysis by Haushofer of a glauconitic limestone (muschelkalk) from Würzburg is given in J. pr. Ch., xcix. 237.

The glauconite grains are most abundant in the "green sand" of the chalk formation, sometimes constituting 75 to 90 p. c. of the whole. They are often casts of the shells of Rhizopods. The material has also been found in Silurian rocks, and beds of other geological periods, and even in the shells of recent Rhizopods, and in fragments of coral obtained in deep sea soundings (Am. J. Sci., II. xxii. 281). The glauconite of the Silurian, analyzed by Hunt, contains less iron and more alumina than that of the chalk formation.

The following are analyses of material usually called "green earth." It occurs often in the form of pseudomorphs; that of Fassa having the form of pyroxene; of Framont, lining pyroxene crystals and filling cavities among them, as if a result of their alteration. 1, 2, Rammelsberg (Min. Ch., 489); 3, Delesse (Ann. d. M., IV. iv. 351):

		S̈i	A̶l	F̶e	Ḟe	Ṁg	Ċa	Ṅa	K̇	Ḣ

410. CELADONITE. Terre verte de Verone *de Lisle*, Crist., ii. 502, 1783. Grünerde *Hoffm.*, Bergm. J., 519, 1788. Green Earth pt.; Green Earth of Verona. Seladonit *Glock.*, Syn., 198, 1847. Celadonite *Fr.*

Earthy or in minute scales, forming nodules or filling cavities in eruptive rocks. Very soft. Color deep olive-green, celandine-green, apple-green. Feel more or less greasy.

Comp.—Analysis by Klaproth (Beitr., iv. 239):

Mt. Baldo $\ddot{\mathrm{S}}\mathrm{i}$ 53 $\bar{\mathrm{F}}\mathrm{e}$ 28 $\dot{\mathrm{M}}\mathrm{g}$ 2 $\dot{\mathrm{K}}$ 10 $\dot{\mathrm{H}}$ 6=99.

Pyr., etc.—According to Klaproth, and also later, von Kobell, *not* acted on by muriatic acid.

Obs.—From cavities in amygdaloid at Mt. Baldo near Verona.

Named in allusion to the ordinary color of the mineral, *celadon-green*, equivalent in French to sea-green (written *Seladon* in German), for which term the English substituted *celandine-green.*[*] Celadon is the name of one of the characters in a French romance by d'Urfé, entitled Astrée, published in 1610. He was a weak verdant lover of insipid tenderness, and thence the application to the above variety of green. D'Urfé borrowed the name from Ovid; it comes originally from κελάδων, *burning*.

II. UNISILICATES.

411. SERPENTINE. 'Οφίτης pt. *Dioscor.*, v. 161. Ophites pt. *Vitruv.*, *Plin.* Ophitæ, Serpentaria, *Agric.*, Foss., 304, 309, 1546. Marmor Serpentinum, M. Zeblicium, Serpenstein Germanice, Lapis Serpentinus, *B. de Boot*, 1636, pp. 502, 504. Telgsten pt., Ollaris pt., Marmor Serpentinum, M. Zöblizense, Lapis Colubrinus, *Wall.*, 135, 1747. Serpentine *Fr. Tri.* Wall. 1753. Serpentin, Zöblitzer S., *Cronst.*, 76, 1758.

Orthorhombic? In distinct crystals, but only as pseudomorphs. Sometimes foliated, folia rarely separable; also delicately fibrous, the fibres often easily separable, and either flexible or brittle. Usually massive, fine granular to impalpable or cryptocrystalline; also slaty.

H.=2·5—4, rarely 5·5. G.=2·5—2·65; some fibrous varieties 2·2—2·3; retinalite, 2·36—2·55. Lustre subresinous to greasy, pearly, earthy; resin-like,[*] or wax-like; usually feeble. Color leek-green, blackish-green; oil and siskin-green; brownish-red, brownish-yellow; none bright; sometimes nearly white. On exposure, often becoming yellowish-gray. Streak white, slightly shining. Translucent—opaque. Feel smooth, sometimes greasy. Fracture conchoidal or splintery. Polarization in crystals, none, or only irregular colors, as in amorphous or cryptocrystalline substances; usually apparent in laminated and fibrous varieties, with the bisectrix negative and normal to the plane of lamination or to that of the fibrous structure.

Var.—Many unsustained species have been made out of serpentine, differing in structure (massive, slaty, foliated, fibrous), or, as supposed, in chemical composition; and these now, in part, stand as varieties, along with some others based on variations in texture, hardness, etc.

A. MASSIVE. (1) *Ordinary massive.* (*a*) *Precious* or *Noble Serpentine* (Edler Serpentin *Germ.*) is of a rich oil-green color, of pale or dark shades, and translucent even when in thick pieces; and (*b*) *Common Serpentine*, when of dark shades of color, and subtranslucent. The former has a hardness of 2·5—3; the latter often of 4 or beyond, owing to impurities.

2. *Resinous.* *Retinalite* Thomson (Min., i. 201, 1836) is massive serpentine, having honey-yellow to light oil-green colors, and waxy or resin-like lustre and aspect. H.=3·5; G.=2·47—2·52, Grenville, Hunt, 2·36—2·38, Calumet Id., Hunt. It much resembles deweylite. It affords, on analysis, 3 p. c. more of water than ordinary serpentine; and it is probable that the mineral is a mixture of serpentine and deweylite. Named from ῥετινή, *resin*, and from specimens obtained at Grenville, C. W. *Vorhauserite* Kenngott (Min. Forsch., 1856–57, 71) is the same, though brown to greenish-black in color. H.=3·5; G.=2·45. From the Fleims valley, Tyrol.

3. *Porcellanous; Porcellophite.* The "meerschaum" of Taberg & Sala is a soft earthy serpen-

---

[*] Jameson has *seladon-green* (from Werner) in his Treatise on the External Characters of Minerals 1805; and *celandine-green* in his System of Mineralogy i. 466, 1816.

tine, resembling meerschaum in external appearance (Berlin, Ak. H. Stockh., 1840). This variety is sometimes very soft when first taken out. A variety resembling compact lithomarge occurs at Middletown, Delaware Co., Pa. (anal. 37). It has a smooth, porcelain-like fracture; H.=3·5, G.=2·48.

4. *Bowenite* Dana (Min., 265, 1850, Nephrite *Bowen*, Am. J. Sci., v. 346, 1822) is massive, of very fine granular texture, and much resembles nephrite, and was long so called. It is apple-green or greenish-white in color; G.=2·594—2·787, Bowen; and it has the unusual hardness 5·5—6, which is some evidence that this variety may be a good species, although proved by Smith & Brush to be identical with serpentine in composition. From Smithfield, R. I.

B. LAMELLAR.

5. *Antigorite* Schweizer (Pogg., xlix. 595, 1840) is thin lamellar in structure, easily separating into translucent or subtransparent folia; H.=2·5; G.=2·622; color brownish-green by reflected light, and leek-green by transmitted; feel smooth, but not greasy. Polarizes light, according to Haidinger. Named from the locality, Antigorio valley, Piedmont.

6. *Williamsite* Shepard (Am. J. Sci., II. vi. 249, 1848) is a lamellar impure serpentine, of apple-green color, with H.=4·5 and G.=2·59—2·64, from Texas, Pa. Does not doubly refract, Desel. Graduates into a massive granular variety.

C. THIN FOLIATED.

7. *Marmolite* Nuttall (Am. J. Sci., iv. 19, 1822, but shown to be a variety of serpentine by Vanuxem, J. Acad. Sci. Philad., iii. 133, 1823) is thin foliated; the laminæ brittle but easily separable, yet graduating into a variety in which they are not separable (which variety has sometimes been called in the United States *kerolite*). G.=2·41; lustre pearly; colors greenish-white, bluishwhite, to pale asparagus-green. From Hoboken, N. J. Folia from Hoboken without polarization, according to Websky; feebly polarizing, according to Descloizeaux.

8. *Thermophyllite* A. Nordenskiöld (Beskrifn. Fin. Min., 160, 1855, Hermann, J. pr. Ch., lxxiii. 213). Occurs in small scaly crystals aggregated into masses, with an amorphous steatite-like base. B.B. crystals exfoliate like vermiculite or pyrophyllite. H.=2·5; G.=2·61, Nord.; 2·56, Herm. Lustre of cleavage surface pearly; color light brown to silver-white and yellowish-brown. Optically biaxial; the axial angle 22° 20′; bisectrix negative, normal to plane of cleavage, Miller. From Hopansuo, Finland.

D. FIBROUS.

9. *Chrysotile* v. Kobell (J. pr. Ch., ii. 297, 1834, xxx. 467, 1843; Schillernder Asbest; Amianthus pt.) is delicately fibrous, the fibres usually flexible and easily separating; lustre silky, or silky metallic; color greenish-white, green, olive-green, yellow, and brownish; G.=2·219. Often constitutes seams in serpentine. It includes most of the silky *amianthus* of serpentine rocks. The original chrysotile was from Reichenstein.

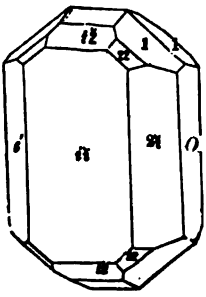
10. *Picrolite* Hausmann (Moll's Efem., iv. 401, 1808) is columnar, but fibres or columns not easily flexible, and often not easily separable, or affording only a long splintery fracture; color dark green to mountain-green, greenish, gray, and brown. The original was from Taberg, Sweden.

Metaxite Breithaupt (Char., 113, 326, 1832) is picrolite, consisting of separable but brittle columns, of a greenish-white color, and weak pearly lustre; H.=2—2·5; G.=2·52. From Schwarzenberg. Passes into a laminated variety.

Baltimorite Thomson (Phil. Mag., xxii. 191, 1843) is picrolite from Bare Hills, Md., of a grayish-green color; silky lustre, opaque, or subtranslucent, with H.=2·5—3.

E. CRYSTALLIZED SERPENTINE. The observed crystals are all pseudomorphs. The most common have the form of chrysolite, and the annexed figure represents one of this kind. Rose has observed some crystals which were still partly chrysolite. Delesse states that the serpentine of Odern graduates into feldspar, and appears to have been derived from the alteration of that mineral. Other kinds are pseudomorphs after pyroxene, amphibole, spinel, chondrodite, garnet, phlogopite, sphene, and chromic iron. Even the foliated and fibrous kinds may be partly pseudomorphous. If *marmolite* or *thermophyllite* is truly crystallized serpentine, as seems probable, the crystallization of the species is actually *micaceous*, like that of chlorite and talc.

412



F. SERPENTINE ROCKS. Serpentine often constitutes rock-masses. It frequently occurs mixed with more or less of dolomite, magnesite, or calcite, making a rock of clouded green, sometimes veined with white or pale green, called *verd-antique*, or *ophiolite*. Ophiolite is styled by Hunt (1) *dolomitic*, (2) *magnesitic*, or (3) *calcitic*, according as the serpentine is mixed with dolomite, magnesite, or calcite. Serpentine rock is sometimes mottled with red, or has something of the aspect of a red porphyry; the reddish portions containing an unusual amount of oxyd of iron. Any serpentine rock cut into slabs and polished, is called *serpentine marble*.

Comp.—O. ratio for $\dot{\mathrm{Mg}}$, $\ddot{\mathrm{Si}}$, $\dot{\bar{\mathrm{H}}}$=3 : 4 : 2, corresponding to 2 $\ddot{\mathrm{Si}}$, 3 $\dot{\mathrm{Mg}}$, 2 $\dot{\bar{\mathrm{H}}}$=Silica 44·14, magnesia 42·97, water 12·89. Formula, as commonly written, 2 $\dot{\mathrm{Mg}}\ddot{\mathrm{Si}}+\dot{\mathrm{Mg}}\dot{\bar{\mathrm{H}}}^2$. But as chrysolite is especially liable to the change to serpentine, and chrysolite is a *unisilicate*, and the change consists in a loss of some $\dot{\mathrm{Mg}}$, and the addition of water, it is probable that part of the water takes the place of the lost $\dot{\mathrm{Mg}}$, so that the mineral is essentially a hydrated chrysolite of the formula $(\frac{3}{4}\dot{\mathrm{Mg}}+\frac{1}{4}\dot{\bar{\mathrm{H}}})^2\ddot{\mathrm{Si}}+\frac{1}{2}\dot{\bar{\mathrm{H}}}$. The relation in O. ratio to kaolinite and pinite corresponds with this view of the formula.

Analyses: A. *Massive Serpentine.* 1, Hartwall (Jahresb., ix. 204); 2, Scheerer (Pogg., lxviii. 328); 3, Hermann (J. pr. Ch., xxxii. 499); 4, Genth (Am. J. Sci., II. xxxiii. 201); 5, Kersten (J. pr. In anal. 3, G.=2·57; 12, G.=2·546–2·553; 13, G.=2·547; 24, G=2·597; 26, G.=2·546; 40, G.=2·593; 41, G.=2·55; 44, H.=3·5; 48, G.=2·644; 64, G.=2·49; 76, G.=2·607. No. 84 accompanies the chrysotile of No. 65.

On composition of *serpentine rocks*, and of the carbonate mixed with serpentine in verd antique marble, see *Jackson* in Proc. N. H. S. Bost., 1856, and Am. J. Sci., II. xxiii. 123; *T. S. Hunt*, Am. J. Sci., II. xxvi. 234, and Logan's Rep., 1863, p. 609; also *Haughton*, Phil. Mag., IV. x 253, where he gives the composition of the red base of a "serpentine porphyry," so called because of its aspect; *C. Schmidt*, Ann. Ch. Pharm., cii. 190, on the rock near the Tuscan boric acid fumaroles.

An impure *serpentine* from Aker, Sudermannland, transparent and yellowish, afforded Lychnell (Ak. H. Stockh., 1826) S̈i 35·28, Äl 13·73, Ḟe 1·79, Ṁg 35·35, Ḣ 7·33, C̈ and bitumen 6·28=99·76. Berzelius referred it to pyrosclerite.

Von Hauer analyzed a mineral from near Baltimore, which he calls *baltimorite*, that afforded him (Jahrb. G. Reichs., 1853) S̈i 27·15, Äl 18·54, Ċa 15·08, Ṁg 26·00, Ḣ 13·23=100. G. J. Brush found in the *metaxite* of Schwarzenberg (priv. contrib.) only 0·78 p. c. of Äl, with 45·03 S̈i, and 2·98 Ḟe.

Nuttall gave the following incorrect analysis of the marmolite of Hoboken in connection with his first description of the mineral (Am. J. Sci., iv. 21, 1822): S̈i 36·0, Ṁg 46·0, Ċa 2·0, Ḟe and C̈r 0·5, Ḣ 15·0.

Stromeyer found of oxyd of nickel 0·32 to 0·45 p. c. in the serpentine of Roraas; 0·30 in that of Sundal; and 0·22 in that of Saxony. Lynchnell obtained 2·24 p. c. from one serpentine. Hunt has detected it in the serpentine of the Green Mountains generally, that of Roxbury, Vt., of New Haven, Ct., of Hoboken, N. J., of Cornwall, Eng., of Banffshire, Scotl., of the Vosges, Fr.; but none in the ophiolites of the Azoic (Laurentian) rocks of Canada, or the serpentine of Easton, Pa., or of the wax-yellow variety of Montville, N. J., or an olive-green from Phillipstown, N. Y., or a yellowish-green from Newburyport, Mass., having G.=2·551. See also anal. 4, 45–47, 62.

Pyr., etc.—In the closed tube yields water. B.B. fuses on the edges with difficulty. F.=6. Gives usually an iron reaction. Decomposed by muriatic and sulphuric acids. Chrysotile leaves the silica in fine fibres.

Obs.—Serpentine often constitutes mountain masses. It is a metamorphic rock, it resulting from the alteration of other rocks, and mostly of those of sedimentary origin; and is of various periods in origin, from the Azoic age upward.

Crystals of serpentine (pseudomorphous) occur in the Fassa valley, Tyrol; near Miask at Lake Auschkul, Barsovka, Katharinenburg, and elsewhere; in Norway, at Snarum; etc. Fine precious serpentines come from Fahlun and Gulsjö in Sweden, the Isle of Man, the neighborhood of Portsoy in Aberdeenshine, in Cornwall, Corsica, Siberia, Saxony, etc. The names of many localities are given above.

In N. America, in *Maine*, at Deer Isle, precious serpentine of a light green color. In *Vermont*, at New Fane, Cavendish, Jay, Roxbury, Troy, Westfield. In *Mass.*, fine at Newburyport; at Blanford with schiller spar, and the marmolite variety; also at Westfield, Middlefield, Lynnfield, Newburyport, and elsewhere. In *R. Island*, at Newport: the bowenite at Smithfield. In *Conn.*, near New Haven and Milford, at the verd-antique quarries. In *N. York*, at Phillipstown in the Highlands; at Port Henry, Essex Co.; at Antwerp, Jefferson Co., in crystals; at Syracuse, east of Major Burnet's, interesting varieties; in Gouverneur, St. Lawrence Co., in crystals, and also in Rossie, two miles north of Somerville; at Johnsburg in Warren Co; Davenport's Neck, Westchester Co., affording fine cabinet specimens; in Cornwall, Monroe, and Warwick, Orange Co., sometimes in large crystals at Warwick; and from Richmond to New Brighton, Richmond Co. In *N. Jersey*, at Hoboken, with brucite, magnesite, etc., and the marmolite variety; also at Frankfort and Bryan; at Montville, Morris Co., silky fibrous (chrysotile) and retinalite, with common serpentine. In *Penn.*, massive, fibrous, and foliated, of various colors, purple, brown, green, and gray, at Texas, Lancaster Co.; also at Nottingham and West Goshen, Chester Co.; at Westchester, Chester Co., the *williamsite;* at Mineral Hill, Newtown, Marple, and Middletown, Delaware Co., a variety looking like meerschaum or lithomarge at Middletown; at Easton, pseudomorphous after pyroxene and amphibole. In *Maryland*, at Bare Hills; at Cooptown, Harford Co., with diallage; also in the north part of Cecil Co. In *Canada*, at Orford, Ham, Bolton, etc. In *N. Brunswick*, at Crow's Nest in Portland.

Serpentine admits of a high polish, and may be turned in a lathe, and is sometimes employed as a material for ornaments, vases, boxes, etc. At Zöblitz in Saxony, Bayreuth, and in Franconia, several hundred persons are employed in this manufacture. Verd-antique marble is clouded with green of various shades, and is a beautiful material for table and ornamental indoor work. Exposed to the weather it wears uneven, owing to its unequal hardness, and soon loses its polished surface.

The names *Serpentine*, *Ophite*, *Lapis colubrinus*, allude to the green serpent-like cloudings of the serpentine marble. *Retinalite* is from ῥητίνη, *resin; Picrolite*, from πικρός, *bitter*, in allusion to the magnesia (or Bittererde) present; *Thermophyllite*, from θέρμη, *heat*, and φύλλον, *leaf*, on account of the exfoliation when heated; *Chrysotile*, from χρυσός, *golden*, and τίλος, *fibrous; Metaxite*, from μέταξα, *silk; Marmolite*, from μαρμαίρω, *I shine*, "in allusion to its pearly and somewhat metallic lustre" (Nuttall).

Artif.—Formed by A. Gages in a transparent amorphous mass, by placing a solution of gelatinous silicate of magnesia in a dilute solution of potash. It is deposited after some months' standing. (Rep. Brit. Assoc., 1863, 203.)

412 **BASTITE**, or **SCHILLER SPAR**. (Talkart *v. Trebra*, Erfahr. Inn. Gebirge, 97, 1785. Schillerspath (fr. Baste) *Heyer*, Crell's Ann., 1786, i. 335, ii. 147. Schillerstein *Wern.*, 1800, Ludw., 50, 1803. Diallage pt. *H.*, Tr., 1801. Metalloidal diallage pt. Bastit *Haid.*, Handb., 523, 1845.) Bastite is an impure foliated serpentine, occurring imbedded in serpentine rock, and is supposed to be a result of the alteration of a foliated mineral of the Pyroxene group, as long since announced by G. Rose. That of Baste, the original locality, was derived, according to Streng, from the enstatite (protobastite) of the region (see ENSTATITE, p. 208). It has H.=3·5–4; G.=2·5–2·76; lustre metallic pearly, bronze-like (to which the German name *schiller* alludes), to vitreous, and color leek-green to olive- and pistachio-green, and pinchbeck-brown. Besides the direction of perfect cleavage, there are two inclined to one another about 87° (Naumann), which is the cleavage of enstatite and hypersthene. According to Descloizeaux, it is probably orthorhombic, and has a negative bisectrix, which is normal to the plane of cleavage, and gives for the axial divergence 60° to 70°. A kind from Todtmoos in the Schwarzwald is thin foliated cleavable, and has a dark green color, but is metallic pearly on the cleavage-face; H.=3·4; G.=2·55; and shows under the microscope in polarized light that it is not homogeneous.

Analyses: 1, 2, Köhler (Pogg., xi. 192); 3, W. Hetzer (C. E. Weiss, Pogg., cxix. 446):

3. Todtmoos (?)	43·77	6·10	—	7·14	—	30·92	1·17	2·79[b]	8·51=100·40.

[a] With some Cr^2O^3.

[b] 1·67 CO^2 plus 1·12 org. subst.

In the closed tube it affords ammoniacal water. B.B. becomes brown and is slightly rounded on the thin edges. With borax reactions of iron. Imperfectly decomposed by muriatic acid, completely so by sulphuric. A mineral resembling schiller spar occurs in serpentine in Middletown, Delaware Co., Pa.

Phæstine (Phästin *Breith.*, Char., 29, 180, 1823, 115, 1832) resembles somewhat schiller spar, and, according to Breithaupt, is altered bronzite. It is foliated, but the cleavage is not very easy; H.=1–1½; G.=2·825; lustre pearly; color yellowish-gray; feel greasy, talc-like. It is from Kupferberg in the Fichtelgebirge, and occurs distributed through serpentine. It has not been analyzed.

413. DEWEYLITE. *Emmons*, Man. Min. and Geol., 1826. Gymnite *Thomson*, Phil. Mag., xxii. 191, 1843.

Amorphous, and having some resemblance to gum arabic, or a brownish or yellow resin.

H.=2–3·5. G.=2·246, Middlefield, Shepard; 2·19–2·31, Bare Hills, Tyson; 2·216, ib., Thomson; 1·936–2·155, Tyrol, Œllacher. Lustre greasy. Color whitish, yellowish, wine-yellow, greenish, reddish. Translucent. Brittle, and often much cracked.

Comp.—O. ratio for $\dot{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=2 : 3 : 3. Formula $(\frac{2}{3}\dot{\text{Mg}}+\frac{1}{3}\dot{\text{H}})\ddot{\text{Si}}+\frac{4}{3}\dot{\text{H}}$=Silica 40·2, magnesia 35·7, water 24·1=100.

Analyses: 1, Shepard (Am. J. Sci., xviii. 31, 1830, analysis imperfect); 2, Brush (this Min., 296, 1854); 3, Thomson (Phil. Mag., 1843, 191); 4, Œllacher (ZS. G., iii. 222); 5, v. Kobell (Münch. gel. [a] After separation of 4·78 $Cu\,O\,C\,O^2$, 0·85 $Fe^2\,O^3$.

G. of anal. 6=2·186; of anal. 7, 2·107.

Pyr., etc.—In the closed tube gives off much water. B.B. becomes opaque, and fuses on the edges. Decomposed by hydrochloric acid.

Obs.—Occurs with serpentine at the localities above mentioned.

Named after Prof. Chester Dewey. The gymnite of Thomson, named from γυμνός, *naked*, in allusion to the locality at Bare Hills, Md., is the same species.

Thomson found in another mineral from the United States, labelled Deweylite (G.=2·0964), $\ddot{Si}$ 50·70, $\dot{Mg}$ 23·65, $\dot{H}$ 20·60, $\ddot{\bar{Al}}$ 3·55, $\dot{Fe}$ 1·70 (Am. J. Sci., xxxi. 173); and in another allied mineral, $\ddot{Si}$ 41·42, $\dot{Mg}$ 23·53, $\dot{Na}$ 6·25, $\dot{H}$ 19·86, $\ddot{\bar{Al}}$ 4·47, $\ddot{\bar{Ce}}$ 3·57, $\dot{Fe}$ *tr.*

Artif.—Formed by A. Gages by the method mentioned under SERPENTINE (p. 465).

414. CEROLITE. Kerolith *Breithaupt*, Char., 145, 254, 1823. Cerolith *Glock.*, 1831. Kerolite.

Massive, reniform, compact or lamellar.

H.=2–2·5. G.=2·3–2·4. Lustre vitreous or resinous. Color greenish or yellowish-white, yellow, reddish. Streak uncolored. Transparent—translucent. Feel greasy. Fracture conchoidal. Does not adhere to the tongue.

Comp.—O. ratio for $\dot{R}$, $\ddot{Si}$, $\dot{H}$=1 : 2 : 1½; formula, if two-thirds of the water is basic, $(\frac{1}{2}\dot{H}+\frac{1}{2}\dot{Mg})\ddot{Si}+\frac{1}{2}aq$; making it thus a unisilicate like deweylite, which species cerolite closely resembles in physical characters. It differs in composition from aphrodite, however, only in containing half more water. Analyses: 1, 2, Kühn (Ann. Ch. Pharm., lix. 368):

	$\ddot{Si}$	$\dot{Mg}$	$\dot{H}$
1. Silesia	47·34	29·84	21 04=98·22 Kühn.
2. "	46·96	31·26	21·22=99·44 Kühn.

Maak obtained (Schw. J., lv. 1829) for the same mineral $\ddot{Si}$ 37·95, $\ddot{\bar{Al}}$ 12·18, $\dot{Mg}$ 18·02, $\dot{H}$ 31·00 =99·15. But Kühn states that he and his laboratory pupils found no alumina, and that Maak's analysis must be incorrect. Kühn dried his mineral at 100° C. before the analysis, and hence the less water.

Pyr., etc.—B.B. blackens, but does not fuse.

Obs.—From Frankenstein in Silesia, associated with serpentine, and also, according to Kühn, brucite. Breithaupt unites deweylite to cerolite.

Melling obtained for a mineral from Zöblitz, similar to the above, $\ddot{Si}$ 47·13, $\dot{Mg}$ 36·13, $\dot{H}$ 11·50, $\ddot{\bar{Al}}$ 2·57, $\dot{Fe}$ 2·92=100·25 (Ramm., 1st Suppl., 79). Hermann obtained for an apple-green variety from Lake Itkul (Bull. Soc. Nat. Mosc., xxxviii. 481), $\ddot{Si}$ 47·06, $\dot{Ni}$ 2·80, $\dot{Mg}$ 31·81, $\dot{H}$ 18·33=100. G.=2·27.

The name Cerolite is from κηρός, *wax*, and λιθος.

415. HYDROPHITE. *Svanberg*, Ak. H. Stockh., 1839, Pogg., li. 525. Jenkinsite *Shepard*, Am. J. Sci., II. xiii. 392, 1852. Eisengymnit.

Massive; sometimes in fibrous crusts.

H.=2·5–3·5. G.=2·65, hydrophite; 2·4–2·6, jenkinsite. Lustre feeble, subvitreous. Color mountain-green to blackish-green. Streak paler. Translucent to opaque.

Comp.—Same as for deweylite, except a replacement of part of the magnesia by protoxyd of iron. Analyses: 1, L. Svanberg (l. c.); 2, 3, Smith & Brush (Am. J. Sci., II. xvi. 369):

	$\ddot{S}i$	$\dddot{\bar{A}}l$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{H}$
1. *Hydrophite*	36·19	2·90	22·73	1·66	21·08	16·08, $\dddot{V}$ 0·115=100·755 Svanberg.
2. *Jenkinsite*	38·97	0·53	19·30	4·36	22·87	13·36=99·39 S. & B.
3. "	37·42	0·98	20·60	4·05	22·75	13·48=99·28 S. & B.

Smith & Brush find in jenkinsite the oxygen ratio for the protoxyds, silica, and water, 3 : 4 : 2½, and they mention the nearness to both hydrophite and serpentine. Websky regards hydrophite as impure *metaxite* (ZS. G. Ges., x. 284).

Pyr., etc.—In the closed tube gives off water. B.B. blackens, and fuses at about 3 to a black magnetic globule. With the fluxes gives reactions for iron and manganese. Decomposed by acids.

Obs.—Hydrophite occurs at Taberg in Smaland; and jenkinsite at O'Neil's mine in Orange Co., N. Y., as a fibrous incrustation on magnetite.

Named *Hydrophite* in allusion to the water present; and *Jenkinsite* after J. Jenkins of Monroe.

415A. **Dermatin** *Breithaupt*, Char., 104, 1832. Massive, reniform, or in crusts on serpentine, of a resinous lustre and green color. Feel greasy; odor, when moistened, argillaceous.

Composition, according to Ficinus (Min. Ges. zu Dresden, ii. 215):

	$\ddot{S}i$	$\dddot{\bar{A}}l$	$\dot{F}e$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{H}$, $\ddot{C}$
1.	35·80	0·42	11·33	2·25	23·70	0·83	0·50	25·20=100·08.
2.	40·17	0·83	14·00	1·17	19·33	0·83	1·33	22·00, $\dddot{S}$ 0·43=100·09.

Formula $(\dot{M}g, \dot{F}e)^3 \ddot{S}i^2+6\dot{H}$?, but probably a mixture. B.B. blackens and cracks.

From Waldheim in Saxony. The name is from δέρμα, *skin*, alluding to its occurrence as an incrustation.

416. GENTHITE. Nickel-Gymnite *Genth*, Kell. & Tiedm. Monatsb., iii. 487, 1851. Genthite *Dana*, Am. J. Sci., II. xliv. 256, 1867.

Amorphous, with a delicately hemispherical or stalactitic surface, incrusting.

H.=3—4; sometimes (as at Michipicoten) so soft as to be polished under the nail, and fall to pieces in water. G.=2·409. Lustre resinous. Color pale apple-green, or yellowish. Streak greenish-white. Opaque to translucent.

Comp.—O. ratio for $\dot{R}$, $\ddot{S}i$, $\dot{H}$=2 : 3 : 3, or the same as for deweylite; formula $(\frac{2}{3}(\dot{N}i, \dot{M}g)+\frac{1}{3}\dot{H})^2 \ddot{S}i+\frac{2}{3}\dot{H}$, being a nickel-gymnite. Analyses: 1, Genth (l. c.); 2, T. S. Hunt (Rep. G. Can., 1863, 507):

	$\ddot{S}i$	$\dot{N}i$	$\dot{F}e$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$
1. Texas, Pa.	35·36	30·64	0·24	14·60	0·26	19·09=100·19 Genth.
2. Michipicoten Id.	33·60	30·40	2·25	3·55	4·09	17·10, $\dddot{\bar{A}}l$ 8·40=99·39 Hunt.

After drying at a temperature above 100° C., Hunt obtained (l. c.) $\ddot{S}i$ 35·80, $\dot{N}i$ 32·20, $\dot{H}$ 12·20.

Pyr., etc.—In the closed tube blackens and gives off water. B.B. infusible. With borax in O.F. gives a violet bead, becoming gray in R.F. (nickel). Decomposed by muriatic acid without gelatinizing.

Obs.—From Texas, Lancaster Co., Pa., in thin crusts on chromic iron; and from Webster, Jackson Co., N. C., with chromic iron in serpentine, as an amorphous, reniform, apple-green incrustation; on Michipicoten Id., Lake Superior, of a greenish-yellow to apple-green color. Also reported from near Malaga, Spain, with chromite and talcose schist; and by Wiser, from Saasthal in the Upper Valais.

Röttisite Breith. (B. H. Ztg., xviii. 1, 1859) may be essentially the above. It occurs with phosphate of nickel at Röttis in Voigtland, in amorphous masses and reniform incrustations, apple-green or emerald-green, of little lustre, translucent to subtranslucent, but opaque when earthy, with H.=2—2·25, and G.=2·358—2·370. Winkler deduces the formula $\dot{N}i\ \ddot{S}i+\frac{1}{3}\dot{H}$; and publishes as the result of his analysis (l. c.) $\ddot{S}i$ 39·15, $\dddot{\bar{A}}l$ 4·68, $\dddot{\bar{F}}e$ 0·81, $\dot{N}i$ 35·87, $\dot{H}$ 11·17, with $\dot{C}o$ 0·67, $\dot{C}u$ 0·40, $\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{P}}$ 2·70, $\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{A}}s$ 0·80. But his summation of these numbers is 100·79, or 4·54 more than they foot up; and there is here an unexplained error. The mineral, as Brush has observed, is probably nickel-gymnite.

417. SAPONITE. Terra porcellanea particulis impalpabilibus mollis, pt., Brianzoner Krita pt Smectis, *Engelsk* Walklera, a hwit (Landsend i Cornwall), *Cronst.*, 75, 1758. Seifenstein (fr Cornwall) *Klapr.*, Schrift. nat. Ges. Berlin, vii. 168, 1787, Beitr., ii. 180, v. 22. Steatite of Cornwall *Kirw.*, Min., i. 152, 1794. Soapstone pt. Pierre à Savon *H.* Saponit *Svanberg*, Ak H. Stockh., 1840, 153. Piotine *Svanberg*, Pogg., liv. 267, 1841, lvii. 165. Thalite *Owen*, J. Ac Philad., II. ii. 179, 1852.

Massive. In nodules, or filling cavities.

Soft, like butter or cheese, but brittle on drying. G.=2·266. Lustre greasy. Color white, yellowish, grayish-green, bluish, reddish. Does not adhere to the tongue.

Comp.—A hydrous silicate of magnesia and alumina; but analyses give, naturally, no uniform results for such an amorphous material. Supposing the alumina present as *kaolinite*, the rest, according to most of the analyses, is a silicate allied to *aphrodite*, as if the mineral were a mixture of the two. Analyses: 1, Klaproth (l. c.); 2, Svanberg (l. c.); 3, Haughton (Phil. Mag., IV. x. 253); 4, Svanberg (l. c.); 5, 6, Smith & Brush (Am. J. Sci., II. xvi. 368); 7, 8, Reakirt and Keyser (Am. J. Sci., II. xvii. 180):

		$\dddot{\mathrm{Si}}$	$\bar{\bar{\mathrm{Al}}}$	$\bar{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	Cornwall	45·00	9·25	1·00	24·75	—	—	0·75	18·00=98·75 Klaproth.
2.	"	46·8	8·0	0·4	33·3	0·7	—	—	11·0=100·2 Svanberg.
3.	"	(⅔) 42·28	7·21	—	29·70	—	—	—	18·92 Haughton.

6.	"	48·89	7·23	2·46	24·17	—	0·81		15·66=99·22 Smith & Brush.
7.	"	44·07	4·72	1·70	21·49	3·75	*undet.*		19·96 Reakirt.
8.	"	44·66	7·79		26·60[a]	—	0·16	0·12	*undet.* Keyser.

[a] Contains some lime.

The oxygen ratio for $\dot{\mathrm{R}}$, $\bar{\bar{\mathrm{R}}}$, $\dddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, in 1, is about 2 : 1 : 5 : 3½; in 2, 3⅓ : 1 : 6⅓ : 2½; in 3, 3⅔ : 1 : 7 : 5⅓; in 4, 2 : 1 : 5⅓ : 2; in 5, 3½ : 1 : 8⅓ : 6⅓; in 6, 2½ : 1 : 6⅓ : 3⅓; in 7, 5 : 1 : 11⅔ : 9.

Pyr., etc.—B.B. gives out water and blackens; thin splinters fuse with difficulty on the edges. Decomposed by sulphuric acid.

Obs.—Occurs at Lizard's Point, Cornwall, in veins in serpentine: in the geodes of datolite at Roaring Brook, near New Haven, Ct.; in the trap of the north shore of Lake Superior, between Pigeon Point and Fond du Lac, in amygdaloid (*thalite* of Owen); at Svärdsjö in Dalarne (*piotine* and *saponite*).

Saponite is from *sapo*, *soap*; and piotine from πιότης, *fat*.

Another similar mineral, associated with chalilite of Thomson in amygdaloid at Antrim, Ireland, afforded von Hauer (Kenngott's Min. Not., No. 11) $\dddot{\mathrm{Si}}$ 44·11, $\bar{\bar{\mathrm{Al}}}$ 10·90, $\dot{\mathrm{Fe}}$ 1·05, $\dot{\mathrm{Mg}}$ 18·01, $\dot{\mathrm{Ca}}$ 6·74, $\dot{\mathrm{Mn}}$ and $\dot{\mathrm{K}}$ *tr.*, ign. 24·07=99·88; oxygen ratio nearly 4½ : 3 : 13½ : 12; or for $\dot{\mathrm{R}}+\bar{\bar{\mathrm{R}}}$ and $\dddot{\mathrm{Si}}$, 1 : 1·8. It has H.=2, and is fragile; lustre waxy; color isabella-yellow, or brownish. Softens or slacks in water. Soluble in muriatic acid, affording pulverulent silica.

418. PHOLERITE. Pholerite *Guillemin*, Ann. d. M., xi. 489, 1825. Pholerite pt. *of many authors.* Pholerite, Pelitische Felsittuffe von Chemnitz, *A. Knop.*, Jahrb. Min., 1859, 540.

Orthorhombic. In rhombic and hexagonal scales, like those of kaolinite. Occurs clay-like and compact massive, consisting of an aggregation of scales.

H.=1–2·5. G.=2·35—2·57. Lustre of scales pearly. Color white, grayish-white, greenish-white, yellowish, reddish-brown, violet. Doubly refracting, Knop.

Comp.—O. ratio for $\bar{\bar{\mathrm{R}}}$, $\dddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=3 : 3 : 2; $\bar{\bar{\mathrm{Al}}}^2\dddot{\mathrm{Si}}^3+4\dot{\mathrm{H}}$=Silica 39·3, alumina 45·0, water 15·7=100. Analyses: 1, 2, Guillemin (l. c.); 3, A. Knop (Jahrb. Min., 1859, 540); 4, J. L. Smith (Am J. Sci., II. xi. 58); 5, Mallet (Shep. Min., 1857, Suppl. to Append., p. iv.):

	S̈i	A̶l	F̶e	Ṁg	Ċa	K̇	Ḣ
1. Fins	42·93	42·07	——	——	——	——	15·00=100 Guillemin.
2. "	41·65	43·35	——	——	——	——	15·00=100 Guillemin.
3. Chemnitz	39·34	45·90		——	——	——	14·76=100 Knop.
4. Schemnitz	42·45	42·81	——	tr.		——	12·92=98·18 Smith.
5. Jacksonville, Ala.	42·19	41·30	0·82	——	1·09		14·20=99·60 Mallet.

Pyr., etc.—Yields water. B.B. infusible. Gives a blue color with cobalt solution. Insoluble in acids

Obs.—The pholerite of Guillemin was from nodules of iron ore in the coal mines of Fins, Dept of Allier, France. The Chemnitz mineral is from Niederrabenstein (and also at Zeisigwald, etc.), where it constitutes a rock called by Naumann *pelitische felsittuffe* in the Lower Coal formation; it is various in color, but is shown to consist of crystalline, colorless, doubly refracting scales. The Schemnitz is the gangue of diaspore, and it may be kaolinite impure with diaspore. The Jacksonville is a kaolin, and may be kaolinite; the analysis afforded 4·86 of free silica, and 0·90 of undecomposed material which above is excluded.

The analyses of *kaolinite* have been referred to pholerite under the idea that Guillemin's analysis was incorrect. But the analysis by Knop appears to show that there is a species with the pholerite composition, but not differing from kaolinite in its physical or crystallographic characters.

Named from φολίς, *a scale.*

418A. *Teratolite* Glocker (Grundr., 544, 1839; Terra miraculosa Saxoniæ *C. Richter*, 1732; Saxonische Wundererde *of old Germ. authors;* Eisensteinmark *Breith.*, Char., 147, 1823, 301, 1832). A. Knop holds (Jahrb. Min., 1859, 546) that the teratolite is an impure lithomarge-like pholerite, closely related to the mineral from Chemnitz. It is described as having H.=2—2½, and G.=2·49—2·5; color varied with lavender and other shades of blue, and spots of red, and rarely pearl-gray. It is from an amygdaloidal rock overlaid by coal strata at Planitz near Zwickau in Saxony, It contains much oxyd of iron; but, according to Knop, probably is a mixture of pholerite with some free quartz, pulverized feldspar, hydrate of iron, carbonate of lime, and magnesia. The following is the analysis of Schuler (Freiesleb. Orykt. Sachs., Heft 5):

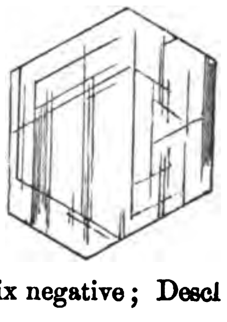
	S̈i	A̶l	F̶e	M̶n	Ṁg	Ċa	K̇	Ḣ
1. Planitz	41·66	22·85	12·98	1·68	2·55	3·04	0·93	14·20 Schuler.

419. KAOLINITE. Talkerde von schuppigen Theilen (fr. Sonne Adit, Halsbrucke, near Freiberg) *Wern.*, Ueb, 218, 1780. Erdiger Talk *Hofmann*, Bergm. J., 160, 1789; *Karst.*, Tab., 32, 1800. ? Talc granuleux *H.*, Tr., iii. 1801. Nacrite pt. *Brongn.*, Min., i. 505, 1807. Schuppiger Thon *Karst.*, Tab., 91, 1808. Nakrit *Breith.*, Char., 94, 318, 1832. Pholerite pt. *many authors.* Kaolinite *S. W. Johnson*, Am. J. Sci., II. xliii. 351, 1867.

Medulla Saxi, *Germ.* Steinmarck, pt., *Agric.*, Interpr., 466, 1546 = Lithomarge pt. Karnat *Breith.*, Handb., ii. 359, 1841 = Steinmark von Rochlitz *Klapr.*, vi. 285, 1815. Terra Samia, Collyrium, Aster, *Plin.*, xxxv. 53. Marga porcellana, Leucargilla, pt., *Wall.*, 22, 1747. Terra Porcellanea *Cronst.*, 73, 1758. Porcelain Clay. Kaolin. Porzellanerde, Porzellanthon, *Germ.* Argiles à porcelaine *Fr.* Terre à foulon pt. *Fr.*= Fuller's Earth.

Orthorhombic. $I \wedge I = 120°$. In rhombic, rhomboidal, or hexagonal scales or plates; sometimes in fan-shaped aggregations; usually constituting a clay-like mass, either compact, friable, or mealy; base of crystals lined (f. 413), arising from the edges of superimposed plates. Cleavage: basal, perfect. Twins: the hexagonal plates made up of six sectors.

413



H.=1–2·5. G.=2·4–2·63. Lustre of plates, pearly; of mass, pearly to dull earthy. Color white, grayish-white, yellowish, sometimes brownish, bluish, or reddish. Scales transparent to translucent. Scales flexible, inelastic; usually unctuous and plastic. Optically biaxial; axial plane normal to the base, and to a side of the hexagon; axes quite divergent; bisectrix negative; Descl

Var.—1. *Argilliform.* Soft, clay-like; ordinary kaolinite; under the microscope, if not without, showing that it is made up largely of pearly scales. The constituent of most, if not all, pure kaolin. G.=2·627, fr. Freiberg, Breith.; 2·6, fr. Schneckenstein, Clarke.

2. *Fariniform.* Mealy, hardly coherent. consisting of pearly angular scales, anal. 3–6, 9.

3. *Indurated; Lithomarge* (*Steinmark* Germ.). Firm and compact; H.=2—2·5. When pulverized, often shows a scaly texture (anal. 17–24). G.=2·6, fr. Cainsdorf, solid var., anal. 23. *Tuesite* of Thomson is a lithomarge from Scotland, used sometimes for slate pencils; H.=2·5; G.=2·43—2·56; color milk-white.

4. *Ferruginous; Carnat* Breith. A firm lithomarge of a reddish-white or flesh-red color; the color owing to the presence of some oxyd of iron replacing the alumina; H.=2—3; G.=2·543. Streak colorless; smooth to the touch (anal. 15, 16). Also brownish-red (anal. 21).

Comp.—O. ratio for $\overset{...}{\mathrm{R}}$, $\overset{..}{\mathrm{Si}}$, $\dot{\mathrm{H}}$=3 : 4 : 2; whence, if half the water be basic, $(\frac{1}{2}\dot{\mathrm{H}}^3+\frac{1}{2}\overset{...}{\mathrm{Al}})^2\overset{..}{\mathrm{Si}}^3$; (as usually written, $\overset{...}{\mathrm{Al}}\overset{..}{\mathrm{Si}}^2+2\dot{\mathrm{H}}$)=Silica 46·3, alumina 39·8, water 13·9=100.

Analyses: 1, W. S. Clarke (Ann. Ch. Pharm., lxxx. 122); 2, Pisani (C. R., liii. 1072); 3, R. Müller (B. H. Ztg., xxiv. 336); 4, Genth (Am. J. Sci., II. xxviii. 251); 5, 6, Johnson, Burton (Am. J. Sci., II. xliii. 354, 358); 7, A. Knop (Jahresb., 789, 1859); 8, R. Richter (Pogg., xc. 320); 9, Stolba (J. pr. Ch., xciv. 116); 10, Smith (Am. J. Sci., II. xi. 58); 11, Boussingault (Ann. d. [a] After separating oxyd of iron 0·18, Ca O 0·98, by muriatic acid (Genth). [b] Contains some free silica.

[c] Na O.

Pyr., etc.—Same as for pholerite.

The mineral from Chaudière Falls exfoliates in white cauliflower-like shapes (Hunt).

Obs.—Ordinary kaolin is a result of the decomposition of aluminous minerals, especially the feldspars of granitic and gneissoid rocks and porphyries. In some regions where these rocks have decomposed on a large scale, the resulting clay remains in vast beds of *kaolin*, usually more or less mixed with free quartz, and sometimes with oxyd of iron from some of the other minerals present. Pure kaolinite in scales often occurs in connection with iron ores of the Coal formation. It sometimes forms extensive beds in the Tertiary formation, as near Richmond, Va. Also met with accompanying diaspore and emery or corundum.

Occurs in the coal formation at Cache-Aprés in Belgium; also in the same at Schlan in Bohemia, and at Röhe; in argillaceous schist at Lodève, Dept. of Hérault, France; at the Einigkeit mine at Brand, near Freiberg, and elsewhere in Saxony; as kaolin at Diendorf (Bodenmais) in Bavaria at Zeisigwald near Chemnitz; as the gangue of topaz at Schneckenstein; with emery and margarite at Naxos; as the gangue of diaspore at Schemnitz; as the material of pseudomorphs after prosopite at Altenberg (anal. 8), showing well the hexagonal scales (Johnson & Blake); with fluor at Zinnwald, a white powdery substance consisting of hexag. scales; at Rochlitz (*carnat*) in a porphyritic rock; in seams in an argillaceous rock on the Tweed (*tuesite*), the Latin name of which place is *Tuesis*. At Yrieix, near Limoges, is the best locality of kaolin in Europe (a discovery of 1765); it affords material for the famous Sèvres porcelain manufactory. The dark-colored clay of Stourbridge, England, is made up in large part of transparent laminæ (J. & B.).

In the U. States, kaolin occurs at Newcastle and Wilmington, Del.; at various localities in the limonite region of Vermont (at Brandon, etc.), Massachusetts, Pennsylvania; Jacksonville, Ala.; Edgefield, S. C.; near Augusta, Ga.; and Johnson & Blake observed transparent hexagonal scales abundantly in a blue fire-clay from Mt. Savage, Md.; in the white clay of Brandon, Vt., Beekman, N. Y., Perth Amboy, N. J., Reading, and a locality in Chester Co., Pa., Long Island, and in white and colored clays of various other places. Near Richmond, Va., the mealy constitutes a bed of considerable extent in the Tertiary formation; at Tamaqua and Summit Hill in Carbon Co., Pa., it occurs in the Coal formation; in a sandstone of the Quebec group, just below the Chaudière Falls, filling seams or fissures, often ¼ in. thick, having an unctuous feel, and consisting of minute soft scales.

The characters of this species have been well defined, and its relation to kaolin explained, in an article by Johnson & Blake (l. c.), by whom the name *kaolinite* was proposed They show that Forchammer's formula for kaolin is the true formula, and also that of kaolinite; and that the two are one in species chemically and physically. They point out that much lithomarge should be included, and that the hexagonal scales, which the massive mineral presents under the microscope, may be detected in all kaolin, and also in some dark-colored fire-clays, although much mixed with impurities. They also show that the plasticity of the kaolinite depends on the fineness of the material, and that kinds not plastic in water may be rendered so by fine trituration. They suggest that the distinction of kaolinite and pholerite may disappear on further chemical investigation.

The earliest recognition of the mineral distinctively is by Werner in 1780 (l. c.), who placed it under talc. It afterward took the name of *earthy talc*, as used by Hoffmann in 1789 (l. c.). The acute Karsten pronounced it a *scaly clay* (*schuppige Thon*), and arranged it accordingly in 1808 (l. c.); but no author of the next twenty years fully adopted his view. In 1807 Brongniart made the species *nacrite* (l. c.), for a *fusible*, anhydrous, pearly *potash-mica*, analyzed by Vauquelin (affording $\ddot{S}i$ 50, $\overset{\dots}{\bar{A}}l$ 26, $\overset{\dots}{\bar{F}}e$ 5, $\dot{C}a$ 1·5, $\dot{K}$ 17·5), and referred to it doubtingly the *earthy talc*, in a note, without any knowledge of it. Hausmann, in 1813 (Handb., 500), says that the *schuppige Talc* of Andreasberg in the Harz (which he says is wrongly called *buttermilchsilber*) may *perhaps* be *schuppige Hydrargillite* (hydrate of alumina) or *Thon*, but an analysis was needed to decide it. Hoffmann, in 1815 (Handb., ii. b, 268), makes it his *first* variety of talc, but queries its nature, and cites an analysis by John of a hydrate of alumina.

In 1832 (l. c.) Breithaupt gave the Saxon mineral the name *nacrite* (nakrit), without any apparent reference in the place to Brongniart's or Vauquelin's previous use of this name. But he at the same time questions whether it may not be identical with *pholerite* (which had been described in 1825). Since then the species has been united to pholerite, under the idea that pholerite was incorrectly analyzed by Guillemin (which may still be true); and Breithaupt, in 1841 (Handb., 391), adopts this view, putting pholerite of Guillemin under *nacrite;* and, moreover, he attributes his name *nacrite* to Vauquelin. This was the state of the question when the description of kaolinite by Johnson and Blake appeared.

Breithaupt, in 1832, stated that the scales were hexagonal; and again in his account of the "nakrit" of Brand near Freiberg. A. Knop, in 1859 (Jahrb. Min. 1859, 594), describes with detail the crystallization of the Schneckenstein mineral; he makes it rhombic, with the planes *I*, *O*, *i-ĭ*, and gives the angle $I \wedge I = 118°$. Descloizeaux, in his Mineralogy (1862), shows that optically the scales from Brand, near Freiberg, are orthorhombic, and makes the angles 120° and 60°; and Johnson & Blake give the same angles as a mean of their measurements of various kaolinites.

The name *Kaolin* is a corruption of the Chinese *Kauling*, meaning *high-ridge*, the name of a hill near Jauchau Fu, where the material is obtained; and the petuntze (peh-tun-tsz) of the Chinese, with which the kaolin is mixed in China for the manufacture of porcelain, is a quartzose feldspathic rock, consisting largely of quartz (S. W. Williams). The word *porcelain* was first given to the china-ware by the Portuguese, from its resemblance to the nacre of the sea-shells *Porcellana* (Cypræas), they supposing it to be made from egg-shells, fish-glue, and fish scales (S. W. Williams).

420. HALLOYSITE. Halloysite *Berthier*, Ann. Ch. Phys., xxxii. 332, 1826. Galapektit Gummit, *Breith.*, Char., 99, 1832. Glagerit *Breith.*, Handb., 357, 1841. Smectite *Salvetat*, Ann Ch Phys., III. xxxi. 102, 1851. Steinmark or Lithomarge pt., Pseudo-Steatite pt., Glossecollite, *Shep.*, Min., 1857, App. to Suppl., p. iii.

? Lenzinit *John.*, Chem. Schrift., v. 193, 1816. ? Severite *Beud.*, Tr., 1824, in index, and ii. 36 1832. ? Nertschinskite *Razoumovski.* Bole pt.

Massive. Clay-like or earthy.

H.=1—2. G.=1·8—2·4. Lustre somewhat pearly, or waxy, to dull Color white, grayish, greenish, yellowish, bluish, reddish. Translucent to opaque, sometimes becoming translucent or even transparent in water, with an increase of one-fifth in weight. Fracture conchoidal. Hardly plastic.

Var.—1. *Ordinary.* Earthy or waxy in lustre, and opaque massive. *Galapectite* is the halloysite of Anglar. *Pseudosteatite* of Thomson & Binney is an impure variety (anal. 8, 9), dark green in color, with H.=2·25, G.=2·469. *Glagerite*, from Bergnersreuth in Bavaria (anal. 10, 11), is proved to be halloysite by Fikenscher; it is white to yellowish-white; G.=2·35—2·382; H.=2—2·5.

2. *Smectite* of Salvetat is greenish, and in certain states of humidity appears transparent and almost gelatinous; it is from Condé, near Houdan, France Breithaupt's *Gummite* (Char., 99, 1832) is a "gum-like halloysite," not adhering to the tongue, from Anglar, though in his Handbuch, where the same locality is mentioned, he quotes Berthier's analysis of *collyrite* from the Pyrenees. *Glossecollite* is milk-white and earthy, but becomes translucent on the edges and a little opaline in water. It forms a seam 1 in. thick in a siliceous Silurian rock in Rising Fawn, Dade Co., Georgia.

3. *Lenzinite* is earthy, compact, white, translucent, and somewhat opaline, from Kall in the Eifel; and brownish, from rifts in pegmatite at La Vilate, near Chanteloube, in France. Leonhard considered it (Handb., 1826) a decomposed semiopal. It is described as not gelatinizing in acids. Named after the German mineralogist Lenz. *Nertschinskite* of Razoumovski, a whitish or bluish earth from Nertschinsk, has been referred to lenzinite. *Severite*, or lenzinite of St. Sever, was first noticed in 1818, and analyzed in that year by Pelletier (J. de Phys., lxxxvi. 251, 1818). It has sometimes the semitransparency of opal, a soft feel, adheres strongly to the tongue, and makes no paste with water; it is from the upper arenaceous stratum in the gypsiferous Tertiary at St. Sever in France. It is not clear whether it belongs here or to kaolinite.

4. *Bole*, in part, may belong here; that is, those colored, unctuous clays containing more or less oxyd of iron, which also have about 24 p. c. of water; the iron gives it a brownish, yellowish, or reddish color; but more investigation is needed before it is known that they are not mere mixtures. *Oropion* of Glocker (Syn., 188, 1847) is a dark brown to black bole; it is the *Bergseife* of Werner (Ueb. Cronst., 189, 1780), having a greasy feel and streak, and H.=1—2; the color is attributed to bituminous matters present. It is from Olkutsch in Poland. Where it belongs is doubtful. The analysis below by Bucholz is of a similar kind from Thuringia; but its identity with Werner's Polish *Bergseife* is not certain.

Comp.—O. ratio for $\dddot{\bar{R}}$, $\dddot{Si}$, $\dot{H}$=3 : 4 : 3; $(\frac{1}{3}\dot{H}^3+\frac{2}{3}\dddot{\bar{Al}})^2\dddot{Si}^3+3\dot{H}$ or $(\dddot{\bar{Al}}\dddot{Si}^2+3\dot{H})$=Silica 43·3, alumina 37·7, water 19·0=100. 20. Thuringia, *Oropion.*	44·0	26·5	8·0	——	0·5	——	——	20·5=99·5 Bucholz.

Pelletier obtained for the *severite* (l. c.) $\ddot{S}i$ 50, $\bar{A}l$ 22, $\dot{H}$ 26=98. Shepard made the *glossecollite* erroneously a hydrated silica containing 17 p. c. of water.

Pyr., etc.—Yields water. B.B. infusible. A fine blue with cobalt solution. Decomposed by acids.

Glossecollite is decomposed by hot sulphuric acid, Pisani.

Obs.—Occurs often in veins or beds of ore, as a secondary product; also in granite and other rocks, being derived from the decomposition of some aluminous minerals. The *Halloysite* of Housscha is derived from graphic granite.

Appendix to Clays.

The following are other earthy hydrous aluminous silicates, all of doubtful character:

420A. SINOPITE *Hausm.*, Handb., 1847; Σινωπις? *Theophr.;* Rubrica *Vitruv.;* Sinopis *Pliny*, Sinopische Erde *Klapr.*, Beitr., iv. 345; Bol de Sinopis *Beud.* A clayey earth of a brick-red color dotted with white, adhering to the tongue. The material analyzed by Klaproth was from Anatolia, Asia Minor. The sinopic earth of the ancients was brought from Cappadocia, and used as a red paint, and may have been a red ochre. Theophrastus speaks of two other kinds of sinopic earth, one whitish, the other between the red and white in color, and called the pure kind because it was used without mixing; besides also an artificial kind make by burning a clay—the clay becoming red owing to the hydrated oxyd of iron present, which was freed from its water by the heat.

420B. MELINITE *Glocker* (Syn., 186, 1847; Gelb-Erde pt. *Wern.*, Hoffm. Min., ii. b, 210; Argile ocreuse jaune pt. *H.*; Yellow ochre pt.) is a yellow clayey material, looking like yellow ochre, more or less lamellar in structure, shining in streak, adhering to the tongue, and soiling the fingers; G.=2·24. The kind analyzed, and to which the name especially belongs, is that from Amberg in Bavaria. Other reported localities are Münden and Schoningen in Hanover; Wehrau, Prussia; Robschütz, Saxony; Vierzon (whence sometimes called *Vierzonite*), Dept. of Cher, and Pourrain, Dept. of Yonne, France.

420C. OCHRAN *Breith.*, Char., 100, 1832. A kind of "bole" of a yellow color from Orawitza, a little greasy in feel, with H.=1—2, and G.=2·4—2·5; streak pale yellow to colorless.

PLINTHITE *Thom.* (Min., i. 323) is a brick-red clay from Antrim, Ireland, having G.=2·342, and H.=2·75, and not adhering to the tongue.

Analyses: 1, Klaproth (l. c.); 2, Thomson (l. c.); 3, Kersten (Schw. J., lxvi. 31); 4, Kühn (Schw. J., li. 466):

	$\ddot{S}i$	$\bar{A}l$	$\bar{F}e$	$\dot{C}a$	Na Cl	$\dot{H}$
1. *Sinopite*	32·0	26·5	21·0	——	1·5	17·0=98·0 Klaproth.
2. *Melinite*	33·23	14·21	37·76	$\dot{M}g$ 1·38	——	13·24=99·82 Kühn.
3. *Plinthite*	30·88	20·76	26·16	2·60	——	19·60=100 Thomson.
4. *Ochran*	31·3	43·0	1·2	——	——	21·0=96·5 Kersten.

These ochreous clays are probably only mixtures. Von Hauer obtained from a "melinite" of unknown locality (Jahrb. G. Reichs., 1858, 428) $\ddot{S}i$ 46·50, $\bar{A}l$, $\bar{F}e$ 40·82 (in one trial $\bar{F}e$ 14·92), $\dot{C}a$ 0·39, $\dot{H}$ 11·50=100.

420D. ORAVITZITE *Breith.*, Handb., 366, 1841. Massive and in nodules, and resembling halloysite, but heavier. H.=2—2½; G.=2·701; lustre waxy; color greenish-white; unctuous. It is supposed to be a hydrous aluminous silicate containing oxyd of zinc. In the glass tube yields much water. B.B. yields, according to Plattner, with soda and borax on charcoal, a slag which is yellow while hot and white on cooling. The oxyd of zinc is probably present as a mixture in the clay.

From Orawitza, Transylvania, with calamine.

420E. HVERLERA *Forchhammer* (Jahresb., xxiii. 265, 1848). A white or reddish clay resulting from the action of sulphuric and carbonic acids on the ferriferous clays of Krisuvig, Iceland Composition $\ddot{\text{Si}}$ 50·99, $\overline{\ddot{\text{Al}}}$ 7·39, $\overline{\ddot{\text{Fe}}}$ 21·21, $\dot{\text{Mg}}$ 19·96, $\ddot{\text{Ti}}$ 0·46=100·01.

420F. KEFFEKILITE (Keffekilith *Fischer*, Mem. Soc. Nat. Moscou, i. 60, 1811). A pearl-gray to grayish-white lithomarge, from the Crimea, having a greasy feel, and somewhat adhering to the tongue, with G.=2·40, John. John obtained (l. c.) $\ddot{\text{Si}}$ 45·00, $\overline{\ddot{\text{Al}}}$ 14·00, $\overline{\ddot{\text{Fe}}}$ 12·25, $\dot{\text{Ca}}$ 2·25, Na Cl 1·50, $\dot{\text{H}}$ 22·00, manganese, chrome (?), magnesia, and loss 3·00. Becomes hard enough to scratch glass by calcination. It is evidently merely a clayey mixture.

Keffekil Tartarorum (of the Tartars) was, according to Cronstedt (Min., 79, 1758), a yellowish-white lithomarge from Tartary, used there as a substitute for soap. It has been referred to sepiolite by some.

420G. MELOPSITE *Breith.* (Handb., ii. 360, 1841). Melopsite is translucent, white, yellowish, grayish, or greenish, has a small conchoidal fracture, adheres a little to the tongue, and resembles in texture the flesh of an apple (whence the name from μῆλον, *apple*, and ὄψον, *meat*, *etc.*) According to Plattner, it consists of silica, alumina, a little magnesia and oxyd of iron, with ammonia, water, and some bitumen. It affords in a glass tube "less water than glagerite."

420H. ACHTARAGDITE *Russian*, before 1847 (Glocker's Syn., 305, 1847. Achtarandit *bad orthog.*). Massive; earthy. Soiling the fingers like chalk. Also in tetrahedral crystals, or combinations of a dodecahedron and tetrahedron, but evidently pseudomorphous. Color grayish-white to greenish-gray; lustre none; fracture earthy. On the Achtaragda, a tributary to the Wilui river, at a locality of idocrase, and containing crystals of idocrase imbedded in it; also 7 m. distant, near Wilui on Mt. Uegernat, with grossularite. Contains silica, alumina, oxyd of iron, lime, magnesia, and water. Supposed by Breithaupt (B. H. Ztg., 1853, 370) to be pseudomorphous after helvite.

421. SAMOITE. *Dana*, Min., 288, 1850; and Geol. Rep. Expl. Exp., 324, 1849.

Stalactitic, with a lamellar structure.

H.=4—4·5. G.=1·7—1·9. Lustre resinous in the fracture. Color white, grayish, or yellowish. Translucent to subtranslucent, not adhering to the tongue nor plastic, being too hard.

Comp.—Analyses: B. Silliman (l. c.):

	$\ddot{\text{Si}}$	$\overline{\ddot{\text{Al}}}$	$\dot{\text{Mg}}$	$\dot{\text{Na}}$	$\dot{\text{H}}$	$\dot{\text{Ca}}\ddot{\text{C}}$
1.	81·25	37·21	0·06	0·06	30·45	0·01=99·04. G.=1·69—1·813.
2.	35·14	31·95	1·05	*tr.*	30·80	1·21=100·15. G.=1·894.

Anal. 1 gives the O. ratio 3 : 8 : 5, and formula $\overline{\ddot{\text{Al}}}^2\ddot{\text{Si}}^2+10\dot{\text{H}}$. No. 2 corresponds nearly to $\overline{\ddot{\text{Al}}}^2\ddot{\text{Si}}^2+10\dot{\text{H}}\,[+\frac{2}{3}\dot{\text{H}}\ddot{\text{Si}}]$. The mode of origin of the mineral renders quite probable the presence of some opal-silica.

Pyr., **etc.**—B.B. infusible. In nitric or muriatic acid gelatinizes, leaving a portion of silica in flakes.

Obs.—Forms stalactites and stalagmites; the former low conical; the latter flattened hemispherical in shape, with a width of 3 inches or so, smooth at surface. They consist within of a series of thin plates closely adhering. When fresh they were soft enough to be cut with a knife, but hardened on exposure. They occur in a lava cavern on the south side of the extinct volcanic island of Upolu, of the Navigator or Samoa group; the cavern was a passage some hundreds of yards long, entered about a mile and a half from the sea by a perpendicular descent of 25 feet, and extending toward and beneath the sea, and also up the mountain to an unascertained distance Its sides and bottom were in places covered with the samoite, which had been formed from the percolating waters. The overlying rock was about 15 feet thick

Samoite of Silliman, Jr. (Dana's Expl. Exp. Geol. Rep., 782), is a kind of feldspar incorrectly analyzed; probably labradorite.

422 PINITE.

Amorphous; granular to cryptocrystalline; usually the latter. Also in crystals, and sometimes with cleavage, but only because pseudomorphs, the form and cleavage being those of the minerals from which derived. Rarely a submicaceous cleavage, which may belong to the species.

H.=2·5–3·5. G.=2·6–2·85. Lustre feeble, waxy. Color grayish-white, grayish-green, pea-green, dull green, brownish, reddish. Translucent—opaque. Acts like a gum on polarized light; Descl.

Comp., Var.—Pinite is essentially a hydrous alkaline silicate. Being a result of alteration, and amorphous, the mineral varies much in composition, and numerous species have been made of the mineral in its various conditions. If crystals of staurolite may vary 20 p. c. in the proportion of silica, much more should a massive mineral which has been made by the metamorphism of other minerals. Variations would naturally exist from the presence of some of the unaltered original mineral, or of some of its ingredients in an uncombined state; and in the case of rock masses, from mixture with free quartz, partially altered or unaltered feldspar, or other substances.

The varieties of pinite here admitted agree closely in physical characters, and in the amount of potash and water present, and their variations are such as are reasonably attributed to the above causes.

The O. ratio for the bases, silica, and water, deduced from the mean of the analyses, is 3 : 4 : 1, whence the formula $(\frac{1}{4}\dot{H}^3+\frac{3}{4}(\dot{R}^3, \bar{\bar{R}}))^2\dddot{Si}^3$=. if $\dot{R}=\dot{K}$ and $\dot{R}^3 : \bar{\bar{R}}=1 : 8$, Silica 46·0, alumina 35·1, potash 12·0, water 6·9=100; or, if $\dot{R}=\frac{1}{3}\dot{Mg}+\frac{2}{3}\dot{K}$ and $\dot{R}^3 : \bar{\bar{R}}=1 : 5$, =Silica 45·9, alumina 32·7, magnesia 2·5, potash 12·0, water 6·9=100; or, if $\dot{Mg} : \dot{K}=5 : 7$ and $\dot{R}^3 : \bar{\bar{R}}=1 : 5$, =Silica 46·2, alumina 33·0, magnesia 3·3, potash 10·6, water 6·9=100. The mineral is related chemically, as it is also physically, to *serpentine* (which has the O. ratio 3 : 4 : 2); and it is an alkali-alumina serpentine, as pyrophyllite is an alumina talc.

The different kinds are either pseudomorphous crystals after (1) iolite; (2) nephelite; (3) scapolite; (4) some kind of feldspar; (5) spodumene; or (6) other aluminous mineral; or (7) disseminated masses resembling indurated talc, steatite, lithomarge, or kaolinite, also a result of alteration; or (8) the prominent or sole constituent of a metamorphic rock, which is sometimes a *pinite schist* (analogous to, and often much resembling, *talcose schist*, and still more closely related to *pyrophyllite schist*). As argillaceous shale often consists of pulverized feldspar, its conversion into pinite schist would be wholly similar to the pseudomorphism of a feldspar crystal into pinite. It is not possible to arrange all the varieties under the above heads. The following are the names that have been introduced, and the characters of the substances to which they are applied:

Var. 1. PINITE. Speckstein [fr. the Pini mine at Aue, near Schneeberg] *Hoffmann*, Bergm. J., 156, 1789; Kieselerde + Thonerde, etc., *Klapr*, ib., 227, 1790. Pinit *Karsten*, Tab., 28, 73, 1800.) The original pinite is in 6- to 9-sided prisms; color brown. Occurs in granite, and is supposed to be pseudomorphous after iolite. Also found at St. Pardoux in Auvergne, at the Puy de Dome, in decomposing feldspar porphyry; at Mühlenthal, near Elbingerode, the prisms 12-sided, lustreless, with H.=2–3. Anal. 1–7.

2. GIESECKITE (fr. Greenland, *Allan*, Ann. Phil., ii. 1813). In 6-sided prisms, probably pseudomorphous after nephelite. H.=3·5. G.=2·78–2·85. Color grayish-green, olive-green, to brownish. Brought by Giesecké from Akulliardsuk and Kangerdluarsuk, Greenland, where it occurs in compact feldspar. Also of similar characters from a pyroxene rock at Diana, N. Y., the prisms often large, and with the basal edges replaced by a plane inclined about 135° to the base. Anal. 8–11.

(*b*) *Lythrodes* Karsten (Mag. Ges. Fr. Berlin, iv. 78, 1810; John, Ch. Unt., i. 171; Splittriger Wernerit *Hausm.*, 520, 1813) has a little less silica and more alumina than the above (anal. 12), but is otherwise essentially the same; it is imperfectly lamellar, scaly in fracture, greasy in lustre; yellow, flesh-red, brownish-red, or spotted with greenish and yellowish; G.=2·51; and is from the zircon-syenite of Fredericksvärn and Laurvig. It is regarded as altered nephelite. Of like composition and origin is the (*c*) *Liebenerite* Marignac (Bibl. Univ., vi. 293, 1848), from a porphyritic feldspathic rock of Mt. Viesena, in Fleimsthal (anal. 13–15); it occurring in 6-sided prisms without cleavage; H =3·5; G.=2·814, v. Hauer; 2·806, Breith.; lustre somewhat greasy; color greenish-gray; and without double refraction.

(*d*) *Dysyntribite* Shepard (Proc. Am. Assoc., 311, 1851, Am. J. Sci., II. xii. 209) is essentially the same with the gieseckite from Diana and elsewhere, Lewis Co., N. Y.; it constitutes masses or a rock, sometimes slaty in structure, and somewhat resembles serpentine, though more waxy in aspect (anal. 18, 19); H.=3–3·5; G.=2·76–2·81; colors often mottled, usually greenish, sometimes reddish or spotted with red. Associated with phlogopite, etc.

(*e*) *Parophite* T. S. Hunt (Rep. G. Can., 1852, 1863) is similar to dysyntribite, but less pure the analyses vary considerably (anal. 20–23), it being, as regarded by Hunt, a rock, and not a simple mineral · the name alludes to a resemblance to serpentine; H.=2·5–3, and it cuts like massive talc; G =2·7–2·784; 2·90, fr. Pownal; colors greenish, yellowish, reddish, grayish. It constitutes a schistose rock at St. Nicholas and Famine R., Can., being an altered shale of the Lower Silurian (Quebec group); also occurs in Stanstead, Can., on the E. shore of L. Memphremagog, with chloritic schist; and at Pownal, Vermont, as a bluish-gray schist, that had been considered a talcose or magnesian schist.

(*f*) A *green mineral* from the Grindelwald glacier (anal. 24), having H.=3·5–4, and G.=2·85, a somewhat waxy lustre, resembling a compact green talc, and described by Fellenberg (Ber. N Ges. Berne, 1866) is very similar to parophite.

(*g*) *Pinitoid*, described by A. Knop (Jahrb. Min. 1859, 558) as a rock, is like dysyntribite in characters, and a schist called "*pinitoid schist*" approaches parophite. *Pinitoid* (anal. 25) has H.=2·5; G.=2·788; color leek-, oil-, and grayish-green. Occurs in the region between Freiberg and Chemnitz, Saxony, pseudomorphous after feldspar, in a half-decomposed granitic porphyry, constituting about 25 p. c. of the rock.

3. WILSONITE *T. S. Hunt* (Rep. G. Can., 1853, 1863) is a pinite pseudomorph, with the form and cleavage of *scapolite*; H.=3·5; G.=2·76–2·78; lustre somewhat pearly; color rose-red; fragments translucent; anal. 16, 17. It is from Bathurst, Can., where it was first found by Dr. Wilson; also St. Lawrence Co., N. Y. *Terenite* (p. 323), from Antwerp, St. Lawrence Co., may be the same.

4. POLYARGITE and ROSITE of Svanberg (Ak. H. Stockh., 1840) are close to the preceding in composition. *Rosite* (anal. 28) is a granular red mineral, occurring in granular limestone at Aker in Södermanland; H.=2·5; G.=2·72. G. Rose and others make it *altered anorthite*. *Polyargite* (anal. 26, 27) occurs in reddish lamellar masses at Tunaberg, Sweden; H.=4; G.=2·768; named from πολύς, *much*, and ἀργός, *sparkle*. The name *Pyrrholite* has been given to a reddish lamellar mineral from Tunaberg, which is very similar to polyargite (Descl. Min., i. 302, 1862); it has H.=3–4; and cleavage surfaces inclined together about 87°; and is apparently anorthite less altered than in rosite and polyargite. It is optically biaxial. The "pinitoid" of Sasbachwald, Duchy of Baden (anal. 35), is *altered oligoclase*, according to Sandberger; H.=2·5.

5. KILLINITE *Thomson* (Min., i. 330, 1836), from Killiney Bay, Ireland, has been stated to have the form and cleavage of spodumene, a mineral that occurs in the vicinity. It has H.=4; G.=2·56–2·66, Thomson; 2·678–2·688, Galbraith; lustre weak vitreous; color greenish-gray, brownish, or yellowish; anal. 29–33.

6. Other pinite has passed under the name of *lithomarge* (Steinmark *Germ.*). That of Zorge (anal. 36) is green, and has G.=3·086, Ramm. The Schemnitz mineral (anal. 37) occurs with dillnite and kaolinite as the gangue of diaspore, and is gray or greenish-gray in color, with H.=2·5–3, G.=2·735. Anal. 47 is of a *lithomarge* from Schlackenwald. That of Ems (anal. 48) is green to white, and *kaolin-like* in consistence, and occurs in clefts in the Spirifer sandstone.

The *compact talc* of Klammberg, Tyrol, is probably pinite or agalmatolite in constitution.

7. AGALMATOLITE (Agalmatolithus, Bildstein (fr. China), *Klapr.*, Beitr., ii. 184, 1797. Pagodite *Napione*, J. de Phys., xlvi. 220, 1798). Like ordinary massive pinite in its amorphous compact texture, lustre, and other physical characters, but contains more silica, so as to afford the formula of a bisilicate, or nearly, and it may be a distinct species. Yet, as above observed, the excess of silica is possibly from free quartz or feldspar as impurity. The Chinese has H.=2–2·5; G.=2·785–2·815, Klapr. Colors same as for pinite, usually grayish, grayish-green, brownish, yellowish. Anal. 38–41.

A similar mineral in composition comes from Nagyag in Transylvania, and Ochsenkopf near Schwarzenberg in Saxony (anal. 44). *Agalmatolite* was named from αγαλμα, *an image*, and *pagodite* from *pagoda*, the Chinese carving the soft stone into miniature pagodas, images, etc. Part of the so-called agalmatolite of China is true pinite in composition, another part is compact pyrophyllite (p. 455), and still another steatite (p. 458). (Brush, Am J. Sci., II. xxvi. 64.)

Oncosin v. Kobell (J. pr. Ch., ii. 295, 1834) is related in composition (anal. 45), and has H.=2; G.=2·8; color apple-green to grayish or brownish; translucent; it occurs in roundish masses imbedded in dolomite with mica, at Passecken near Tamsweg, in Salzburg. (*c*) *Oösite* (Oösit *Marx*, ib., iii. 216, 1834), another related compound (anal. 43), is white to reddish or brownish-red, and occurs in 6- and 12-sided prisms; it is from the Oös valley, duchy of Baden, occurring in what is called pinite-porphyry.

(*d*) *Gongylite* (Gongylit *Thoreld*, Act. Soc. Sci. Fenn., iii. 815, A. Nord., Beskrifn. Finl. Min., 146, 1855) is yellowish or yellowish-brown, and has cleavage in two directions; with H.=4–5; G.=2·7; anal. 42. From a schist called talcose schist at Kimsamo in Finland.

O. ratio for $\dot{R}$, $\ddot{R}$, $\ddot{S}i$, $\dot{H}$, for *agalmatolite*, about 1 : 9 : 18 : 3; for *oncosin*, 1 : 5 : 10 : 1½; for *oösite*, 1 : 10 : 24 : 6; for *gongylite*, 1 : 8 : 8 : 1½.

The following may be impure pinite:

8. *Gigantolite* Nord. (Act. Soc. Sci. Fenn., i. 2, 377, 1840). From gneissoid granite of Tammela, Finland, in large 6- and 12-sided prisms, with basal cleavage; H.=2·5; G.=2·862–2·878: lustre somewhat waxy; color greenish to dark steel-gray, sometimes approaching submetallic in lustre,

owing to the alteration of the original iolite and the presence of uncombined oxyd of iron. (*b*) *Iberite* Svanberg (Œfv. Ak. Stockh., i. 219, 1844), from Montalvan, near Toledo, Spain, is the same mineral in characters; H.=2·5; G.=2·89. Both are a result of the alteration of iolite, and are between pinite and *fahlunite* (p. 484) in composition.

Analyses: 1, 2, Rammelsberg (3d Suppl., 94, Min. Ch., 835); 3–5, Marignac (J. Pharm. Ch., III xii. 150); 6, Rammelsberg (Min. Ch., 836); 7, A. Streng (B. H. Ztg., xx. 266); 8, Stromeyer (Gel. Anz. Gött., iii. 1993, 1819); 9, Pfaff (Schw. J., xlv. 103, 1825); 10, v. Hauer (Jahrb. G. Reichs., 1854, 76); 11, G. J. Brush (Am. J. Sci., II. xxvi. 64); 12, John (Chem. Unt., i. 171); 13, Marignac (l. c.); 14, v. Hauer (l. c., 1853, 147); 15, Œllacher (ZS. Ferdinandeums, 1844, 2); 16, T. S. Hunt (Rep. G. Can., 1863, 483); 17, E. W. Root (Am. J. In a so-called *pinitoid schist* of the valley of Raibl, apple-green in color, Tschermak found (Ber. Ak. Wien, lii. 448): S̈i 62·0, Äl 18·1, Ḟe 4·1, Ṁg 1·6, Ċa 1·5, Ṅa 1·0, K̇ 4·1, Ḣ 6·2, C̈ 0·4=99. There is a large excess of silica, which may be due to free silica, if the rock is not rather a *pyrophyllite schist.*

A pinite-like mineral from the phyllite of Petit-Cœur in the Tarentaise, Savoy, afforded A. Terreil (C. R., liii. 120) S̈i 50·00, Äl 36·45, F̈e 0·37, Ċa, Ṁg 0·45, K̇ 5·01, Ṅa *tr.*, P̈ *tr.*, Ḣ 7·96= 100·24. The composition is the same with that of the containing schist.

Gmelin obtained (Kastn. Arch., i. 226) for the Auvergne pinite, S̈i 55·96, Äl 25·48, etc.; but the later analyses (Nos. 5, 6, above) show that his results are erroneous. The Neustadt red pinite is an anhydrous mineral; it gave Ficinus (Schw. J., xxvi. 280) S̈i 54·6, Äl 23·6, Ḟe 7·8, M̈n 1·6, Ṁg 0·8, K̇ 11·2, Ḣ 1·2=100·8; and Massalin (Trommsdorff's N. J., iv. 2, 324) S̈i 45·0, Äl 30·0, F̈e 12·6, K̇ 12·4=100.

The following are analyses of *gigantolite* and *iberite:* 1, Wachtmeister (Pogg., xlv. 558); 2, Marignac (J. Pharm. Ch., III. xii. 150, Ramm. Min. Ch., 836); 3, Komonen (Nord. Beskrifn. Finl. Min., 151); 4, Norlin (Œfv. Ak. Stockh., 1844, 219):

	S̈i	Äl	F̈e	Ṁn	Ṁg	Ċa	Ṅa	K̇	Ḣ
1. Tamela, *Gigant.*	46·27	25·10	15·60	0·89	3·80	—	1·20	2·70	6·00, F *tr.*, Wachtm.
2. " "	42·59	26·62	15·78	0·95	2·68	—	0·86	5·44	5·89=100·71 Mar.
3. " "	45·5	26·7	13·8	0·9	2·4	—	—	5·8	6·2=101·3 Komon.
4. Montalvan, *Iberite*	40·90	30·74	17·18	1·33	0·80	0·40	0·04	4·57	5·57=101·53 Norlin.

Pyr., etc.—In the closed tube gives off water, which frequently reacts alkaline. B B. some varieties fuse easily with intumescence, while others fuse quietly and with more difficulty. Appreciably attacked by strong muriatic acid.

Obs.—Gieseckite has been attributed by many authors to the alteration of nephelite (elæolite). Pisani (C. R., lxii. 1324) has found the latter mineral from Brevig, Norway, partly altered to a brick-red material which is true gieseckite in nature and composition. On the same specimen is found true translucent elæolite, affording only 1·3 p. c. of water on calcination, and entirely soluble in dilute acids; by the side of this, red spots where alteration has commenced; and beyond, the mineral changed to a brick-red uniform material, mostly opaque, with some translucent spots of unaltered elæolite. This red material afforded 5·9 p. c. of water, and dissolved only partially in dilute nitric acid, leaving an abundant red deposit. On separating the insoluble portion by treatment with cold dilute nitric acid, this afforded, on analysis, S̈i 46·95, Äl 34·65, F̈e 1·86, Ṁg 0·58, Ċa 0·68, Ṅa, Li 0·71, K̇ 8·71, Ḣ 5·58=99·72, thus showing that, besides taking up water, the soda of the elæolite had been replaced almost wholly by potash.

423A. *Neurolite* Thomson (Min., i. 354, 1836) is greenish-yellow, imperfectly foliated in texture, consisting of thin fibres of some breadth but rather obscure, but "not the least appearance of crystallization." H.=4·25. G.=2·476. B.B. whitens, but does not fuse. Composition, according to Thomson, S̈i 73·00, Äl 17·35, F̈e 0·40, Ṁg 1·50, Ċa 3·25, Ḣ 4·30=99·8. From Stanstead, Lower Canada. It has been doubtful what mineral Dr. Thomson had in hand in making his description. But according to T. S. Hunt (Rep. G. Can., 1863, 485), neurolite is a quartzose variety of woodlike agalmatolite. His analysis afforded (l. c.):

S̈i	Äl	Ḟe	Ṁg	Ṅa, K̇	Ḣ
50·30	32·60	*tr.*	1·20	*undet.*	6·50

It occurs at Stanstead, forming a belt 150 feet wide; in some places granular and nearly pure, in others schistose and containing quartz. A thin layer has a banded structure, ligneous in appearance, with a shiny satin lustre. It is translucent, of a wax or amber-yellow color; feel unctuous.

423B. A mineral near pinite in composition has been described by Descloizeaux (Bull. G. Soc., II. xxii. 25). It occurs in rounded grains, of a waxy structure and greenish color, distributed in the anhydrite of Modane. Thin plates without double refraction, according to Descloizeaux. H.=3·

G.=2·66. Yields water in closed tube. B.B. fuses with intumescence to a white enamel Scarcely attacked by muriatic acid. Pisani obtained (Bull. G. Soc., l. c.):

$\ddot{\mathrm{Si}}$ 48·20 $\overset{\cdots}{\mathrm{\bar{A}l}}$ 19·70 $\dot{\mathrm{F}}\mathrm{e}$ 3·38 $\dot{\mathrm{M}}\mathrm{g}$ 12·80 $\dot{\mathrm{C}}\mathrm{a}$ 1·64 $\dot{\mathrm{K}}$, $\dot{\mathrm{N}}\mathrm{a}$, $\dot{\mathrm{L}}\mathrm{i}$ (by loss) 7·22 $\dot{\mathrm{H}}$ 7·06=100.

423. CATASPILITE. Kataspilit *Igelström*, Œfv. Ak. Stockh., 1867, 14.

Pseudomorphous after iolite, and presenting its forms.
H.=2·5. Lustre pearly. Color ash-gray. Subtranslucent.

Comp.—Near pinite. O. ratio for $\dot{\mathrm{R}}$, $\overset{\cdots}{\mathrm{\bar{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=3 : 5 : 8 : 1; $(\frac{3}{8}\,\dot{\mathrm{R}}^3+\frac{5}{8}\,\overset{\cdots}{\mathrm{\bar{A}l}})^2\,\ddot{\mathrm{Si}}^3+\frac{3}{4}\,\dot{\mathrm{H}}$. Analysis: Igelström (l. c.):

$\ddot{\mathrm{Si}}$ 40·05 $\overset{\cdots}{\mathrm{\bar{A}l}}$, with some $\overset{\cdots}{\mathrm{\bar{F}e}}$, 28·95 $\dot{\mathrm{M}}\mathrm{g}$ 8·20 $\dot{\mathrm{C}}\mathrm{a}$ 7·43 $\dot{\mathrm{N}}\mathrm{a}$ 5·25 $\dot{\mathrm{K}}$ 6·90 ign. 3·22

G. J. Brush found in a pale greenish pagodite from China (priv. contrib.) $\ddot{\mathrm{Si}}$ 41·50, $\overset{\cdots}{\mathrm{\bar{A}l}}$, with little $\overset{\cdots}{\mathrm{\bar{F}e}}$, 31·30, $\dot{\mathrm{M}}\mathrm{g}$ 12·25, $\dot{\mathrm{N}}\mathrm{a}$ 0·60, $\dot{\mathrm{K}}$ 6·42, $\dot{\mathrm{H}}$ 7·50=99·67, approaching the above, but affording the O. ratio 3 : 6 : 9 : 3=1 : 2 : 3 : 1. Igelström obtained but 1 p. c. of water in one trial, and in his formula makes the cataspilite anhydrous.

Pyr., etc.—Fuses on charcoal rather easily to an enamel-like bead. Decomposed by muriatic acid, with a separation of flocculent silica.

Obs.—From a gray chlorite rock at Longban, in Wermland, Sweden, distributed through it in druses as large as peas. Named from καταςπιλάζω, in allusion to this mode of occurrence.

424. BIHARITE. Agalmatolith (fr. Retzbanya) *Haid.*, Ber. Min. d. k. k. Hofk., Wien, 1843. Biharit *K. F. Peters*, Ber. Ak. Wien, xliv. 132, 1861.

Massive; fine granular or microcrystalline.
H.=2·5. G.=2·737, yellow var. Lustre greasy, inclined to pearly. Color yellowish to green, brownish, dull wine-yellow, oil-green, leek-green. Translucent to hardly subtranslucent. Feel a little greasy. Optically doubly refracting.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\overset{\cdots}{\mathrm{\bar{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=2 : 1 : 3 : $\frac{1}{2}$, nearly; whence $(\frac{2}{3}\,(\dot{\mathrm{M}}\mathrm{g}, \dot{\mathrm{C}}\mathrm{a})^3+\frac{1}{3}\,\overset{\cdots}{\mathrm{\bar{A}l}})^2\,\ddot{\mathrm{Si}}^3+1\frac{1}{3}\,\dot{\mathrm{H}}$. Analysis: Soltész (l. c.), after removing 4·68 $\dot{\mathrm{C}}\mathrm{a}\,\ddot{\mathrm{C}}$:

$\ddot{\mathrm{Si}}$	$\overset{\cdots}{\mathrm{\bar{A}l}}$	$\overset{\cdots}{\mathrm{\bar{F}e}}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
41·74	18·47	*tr.*	28·92	4·27	*tr.*	4·86	4·46=97·72.

Pyr., etc.—In the tube yields water. B.B. infusible (the green var.), or only fusing on the thinnest edges (yellow).

Obs.—Occurs imbedded in a fine granular limestone in the Biharberg, near Retzbanya.

425. PALAGONITE. Palagonit *Sartorius v. Waltershausen*, Subm. Vulk. Ausbr. Val di Noto, etc., Gött., 1846; Vulk. Gest., 1853. Bunsen, Ann. Ch. Pharm., lxi. 265, 1847, Pogg., lxxxiii. 219, 1851. Melanhydrit *A. Krantz*, Verh. nat. Ver. Bonn, xvi. 154, 1859.

Amorphous. In grains and fragments aggregated into a tufa-like rock, or as a constituent of tufa or volcanic conglomerate.
H.=4—5. G=2·4—2·7; 1·82, melanhydrite. Lustre vitreous or greasy, or like pitchstone. Color amber-yellow, yellowish-brown, colophonite-brown, garnet-red, blackish, black. Streak yellowish, brownish-yellow.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\overset{\cdots}{\mathrm{\bar{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 2 : 4 : *n*; and for bases and silica 3 : 4, as in pinite, kaolinite, and serpentine, to which species the mineral is therefore related. Formula $(\frac{1}{2}\,(\dot{\mathrm{R}}^3, \overset{\cdots}{\mathrm{\bar{F}e}}, \overset{\cdots}{\mathrm{\bar{A}l}})+\frac{1}{2}\,\dot{\mathrm{H}}^3)^2\,\ddot{\mathrm{Si}}^3+n$ aq. Has been regarded by Bunsen a combination of unisilicates $\overset{\cdots}{\mathrm{\bar{R}}}^2\,\ddot{\mathrm{Si}}^3+n$ aq, and bisilicates $(\dot{\mathrm{R}}^3)\,\ddot{\mathrm{Si}}^3+n$ aq, who writes for the palagonite of Iceland the formula $\dot{\mathrm{R}}^3\,\ddot{\mathrm{Si}}^3+\overset{\cdots}{\mathrm{\bar{R}}}^2\,\ddot{\mathrm{Si}}^3+n$ aq; and for that of the Galapagos, $2\,\dot{\mathrm{R}}^3\,\ddot{\mathrm{Si}}^3+\overset{\cdots}{\mathrm{\bar{R}}}^2\,\ddot{\mathrm{Si}}^3+n$ aq.

Analyses by v. Waltershausen (l. c.); means of results after gangue excluded:

		$\dddot{\rm Si}$	$\bar{\dddot{\rm Al}}$	$\bar{\dddot{\rm Fe}}$	$\dot{\rm Mg}$	$\dot{\rm Ca}$	$\dot{\rm Na}$	$\dot{\rm K}$	$\dot{\rm H}$

Pyr., etc.—Yields water. B.B. fuses easily to a black magnetic glass. Decomposed by muriatic acid with gelatinization.

Obs.—Tufas are formed through the action of waters, and often that of heated waters or steam accompanying an eruption of lavas, on the granulated volcanic rock, or volcanic sand; and in the process the protoxyd of iron of the pyroxene of the rock becomes more or less completely changed to sesquioxyd, and water is taken up, and so the palagonite is produced. As the volcanic rock is made up generally of pyroxene and a feldspar always in very variable proportions, uniformity in such results of alteration is not possible.

Bunsen observes that palagonite is the basis of the basaltic tufas of Germany, France, Azores, Canaries, Cape Verdes, Tortugas, and probably also of those of the Pacific Islands. *Melanhydrite* (anal. 14, by Wackernagel, l. c., and Ramm. Min. Ch.) is velvet-black to brownish-black, and occurs in irregular nodules in a decomposed wacke at Schmelzerthal near Honnef, on the Rhine.

Named *palagonite* from Palagonia, one of its localities in Sicily.

426. FAHLUNITE. Fahlunit (fr. Fahlun) *Hisinger*, Min.-Geogr. Sverige, 22, 1808. Triclasit (fr. ib.) *J. F. L. Hausmann*, Moll's Efem., iv. 396, 1808. Hydrous iolite (fr. Abo) v. *Bons* *dorff*, Ak. H. Stockh., 156, 1827. Auralit (ib.) *v. Bonsd.* Hydrous Iolite, Bonsdorffite, *Thoms.*, Min., i. 278, 328, 1836. Raumit (from Raumo, Finl.) *v. Bonsdorff.* Weissit (fr. Fahlun) *Wachtmeister*, Ak. H. Stockh., 1827. Esmarkit *A. Erdmann*, Ak. H. Stockh., 188, 1840. Praseolite (fr. Bräkke) *Erdmann*, ib. Chlorophyllite (fr. Unity, Me.) *C. T. Jackson*, Rep. G. N. Hamp. 152, 1841, Am. J. Sci., xli. 357, 1841. Peplolit (fr. Ramsberg, Swed.) *Carlsson*, Œfv. Ak. Stockh. 241, 1857. Pyrargillit (fr. Helsingfors) *N. Nord.*, Jahresb., xii. 1832, 174. Polychroilith *Weibye*, Jahrb. Min., 1846, 289. Aspasiolit *Scheerer*, Pogg., lxviii. 328, 1846.

In six- to twelve-sided prisms, but derived from pseudomorphism after iolite. Cleavage: basal sometimes perfect.

H.=3·5–5. G.=2·6–2·8. Lustre of surface of basal cleavage pearly to waxy, glimmering. Color grayish-green, to greenish-brown, olive- or oil-green; sometimes blackish-green to black; streak colorless.

Var.—This species is a result of alteration; and considerable variation in the results of analyses should be expected. The crystalline form is that of the original iolite, while the basal cleavage when distinct is that of the new species fahlunite.

1. *Triclasite* and *fahlunite* were from the same locality, Fahlun, Sweden. The mineral has the above characters. *Bonsdorffite* and *auralite* are Bonsdorff's *Hydrous iolite*, from Abo, Finland, and identical with fahlunite. The name triclasite alludes to *three cleavages*, and is therefore bad, as they are not cleavages of the species, but in part of the original iolite. *Fahlunite* dates from the same year.

Esmarkite is fahlunite. Color grayish-green to whitish, with a greasy lustre. G.=2·709; H.=3·5. (*b*) *Praseolite* is similar from Bräkke, near Brevig, in granite. H.=3·5; G.=2·754. (*c*) *Raumite*, from Raumo in Finland, is of like nature and origin, according to A. E. Nordenskiöld (Beskrifn. Finl. Min.), although analysis gives a somewhat different constitution. (*d*) *Chlorophyllite* from Unity, Maine, is like fahlunite in composition, etc.; H. on base of prisms=1·5–3; G.=2·705. Named from χλωρός, *green*, and φύλλον, *leaf*. (*e*) *Peplolite* from Ramsberg, Sweden, has the composition essentially and form of esmarkite; G.=2·68–2·75.

2. *Pyrargillite* is near fahlunite, and probably essentially the same, though containing more water and less of protoxyd bases. Form the same, but cleavage not distinct; color blackish, bluish, liver-brown, or in part dull-red; H.=3·5; G.=2·5: lustre weak resinous. It is from granite near Helsingfors, Finland. Bischof has shown that it is only altered iolite.

3. *Polychroilite* has been referred here. It occurs in six-sided prisms of 120°, without distinct cleavage. H.=3–3·5; lustre greasy; color blue and green of different shades, and also brown and brick-red. Occurs in gneiss at Krageröe, Norway.

4. *Aspasiolite* occurs in prisms like those of fahlunite, but with the cleavage less distinct; H.=3–3·5; G.=2·764; color green to greenish-gray, clouded with brown or red. It is from Krageröe, Norway, with iolite in quartz.

Huronite Thomson (Min., i. 384, 1836). Considered an altered mineral near fahlunite, by T. S. Hunt. Occurs in spherical masses in hornblendic boulders in the vicinity of Lake Huron. Structure partly in imperfect folia, and partly granular. H.=3–3·5; G.=2·86; lustre waxy to pearly; color light yellowish-green; subtranslucent. *Weissite* Wachtmeister, is like fahlunite in most of its characters, but differs in composition, and may belong elsewhere. Occurs of bluish and green colors at Fahlun, in masses as large as hazel-nuts, in chlorite.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}$=1 : 3 : 5 : 1; whence the formula $(\frac{2}{5}(\dot{H}, \dot{R})^3 + \frac{3}{5}(\bar{Al}, \bar{Fe}))^2 \ddot{Si}^3$, the water being basic, and entering, as already suggested, to make up the deficiency of bases in the unisilicate. In some kinds, the same with the addition of $\dot{H}$. The O. ratio of iolite, the original of the species, is 1 : 3 : 5.

Analyses: 1, Hisinger (Afh., iv. 210); 2, 3, Trolle Wachtmeister (Ak. H. Stockh., 1827, 213); 4, Bonsdorff (Ak. H. Stockh., 1827); 5, Malmgren (Arppe's Finsk. Min., 1861, 586, Verh. Min. St. Pet., 1862, 152); 6, Erdmann (Jahresb. 1841, 174); 7, C. T. Jackson (Rep. G. N. H., 1844, 184); 8, Rammelsberg (Min. Ch., 833); 9, Erdmann (l. c.); 10, J. Staudinger (Bonsdorff, l. c.) 11, Carlsson, Amark and Sieurin (l. c.); 12, Nordenskiöld (l. c.); 13, Scheerer (Pogg., lxviii. 328) 14, Wachtmeister (Ak. H. Stockh., 1827):

[a] With some Mn O.

In *polychroilite* Dahl found (l. c.) $\ddot{\mathrm{Si}}$ 52, $\ddot{\bar{\mathrm{Al}}}$ 37, $\ddot{\bar{\mathrm{Fe}}}$ 3, $\dot{\mathrm{Mg}}$ 7, $\dot{\mathrm{Ca}}$ 1, $\dot{\mathrm{H}}$ 1; and Scheerer obtained about 6 p. c. of water. The *huronite* afforded Thomson (l. c.) $\ddot{\mathrm{Si}}$ 45·80, $\ddot{\bar{\mathrm{Al}}}$ 33·92, $\dot{\mathrm{Fe}}$ 4·32, $\dot{\mathrm{Ca}}$ 8·04, $\dot{\mathrm{Mg}}$ 1·72, $\dot{\mathrm{H}}$ 4·16=97·96; it is stated to be infusible and not attacked by acids.

An ash-gray mineral from Potton, Canada East, as analyzed by Tennant, is near weissite in composition. Tennant obtained (Rec. Gen. Sci., iii. 339) $\ddot{\mathrm{Si}}$ 55·05, $\ddot{\bar{\mathrm{Al}}}$ 22·60, $\dot{\mathrm{Fe}}$ 12·60, $\dot{\mathrm{Mn}}$ *tr.*, $\dot{\mathrm{Mg}}$ 5·70, $\dot{\mathrm{Ca}}$ 1·40, $\dot{\mathrm{H}}$ 2·25=99·60; and gives H.=1·75, G.=2·8263. T. S. Hunt says it is probably only a rock, and not a mineral species, as he judges from a specimen he has seen so labelled (private communication).

Gigantolite and *Iberite* much resemble fahlunite, and like it are results of the alteration of iolite, occurring in large six to twelve-sided crystals. But they contain potash, and are therefore related in composition to pinite, of which they seem to be impure varieties. See under PINITE.

Pyr., etc.—Yields water. B.B. fuses to a white blebby glass. Not acted upon by acids. Pyrargillite is difficultly fusible, but is completely decomposed by muriatic acid.

427. GROPPITE. *Svanberg*, Œfv. Ak. Stockh., iii. 14, 1846.

Crystalline, with one distinct cleavage affording a broad cleavage surface, and two others less distinct.

H.=2·5. G.=2·73. Thin splinters translucent. Color rose-red to brownish-red. Streak paler. Fracture splintery.

O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=2 : 3 : 6 : 2, whence, if half the water be basic, $(\frac{1}{2}(\dot{\mathrm{H}}^3, \dot{\mathrm{R}}^3)+\frac{1}{2}(\ddot{\bar{\mathrm{Al}}}, \ddot{\bar{\mathrm{Fe}}}))^2\,\ddot{\mathrm{Si}}^3+\dot{\mathrm{H}}$. Analysis by Svanberg:

$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{Al}}}$	$\ddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
45·01	22·55	3·06	12·28	4·55	0·22	5·23	7·11, undissolved 0·13=100·13.

Pyr.—In a matrass yields water. B.B. whitens, and on thin edges shows only incipient fusion. Svanberg's formula is the same as for ottrelite.

From a limestone at Gropptorp in Sweden.

428. VOIGTITE. *E. E. Schmid*, Pogg., xcvii. 108, 1856. Rastolyte *Shep.*, Min., 1857, Append., p. vi., and Am. J. Sci., II. xxiv. 128.

In small crystals and scales, mica-like in structure and aspect.

H.=2—3. G.=2·91. Lustre pearly. Color leek-green, often yellowish or brownish from alteration. Thin scales translucent.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=1 : 1 : 2 : 1; $(\frac{1}{2}\dot{\mathrm{R}}^3+\frac{1}{2}\ddot{\bar{\mathrm{R}}})^2\,\ddot{\mathrm{Si}}^3+3\,\dot{\mathrm{H}}$, or the same as that of biotite with the addition of water.

Analyses: 1, Schmid (l. c.); 2, Pisani (C. R., liv. 686, Am. J. Sci., xxxiv. 208):

	$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{Al}}}$	$\ddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
1. Ehrenberg	33·83	13·40	8·42	23·01	7·54	2·04	0·96	9·87=99·07 Schmid.
2. *Rastolyte*	34·98	21·88	——	28·44	6·24	——	——	9·22=100·76 Pisani

Pyr., etc.—In a glass tube yields water, sometimes exfoliates, and becomes brown and metallic in lustre. B.B. fuses easily to a black glass, with the reaction of iron. Attacked by muriatic acid, giving a yellow solution, and the insoluble part becomes after some days colorless.

Obs.—Voigtite constitutes the mica in a kind of graphic granite at Ehrenberg near Ilmenau Rastolyte is in ash-gray, reddish, and bluish laminæ, looking like an altered mica, at Monroe, N. Y. mixed with pyrite, and probably formed through the action of the decomposing pyrite on mica.

Named after Mr. Voigt, director of the mines of Saxe-Weimar.

Eukamptite of Kenngott (p. 307) is a similar hydrous biotite with less water.

Another from Rio Janeiro, closely related to the above, has been described by Kenngott in his Uebersicht for 1856–57, p. 80. It is in dull green short prismatic crystals, in granite. Composition, according to v. Hauer (l. c.), $\ddot{\mathrm{Si}}$ 32·33, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 20·47, $\dot{\mathrm{F}}\mathrm{e}$ 26·25, $\dot{\mathrm{M}}\mathrm{g}$, by loss, 7·75, $\dot{\mathrm{C}}\mathrm{a}$ 0·85, $\dot{\mathrm{K}}$ 2·02, ign. 10·33.

429. MARGARODITE. Margarodit *Schafhäutl*, Ann. Ch. Pharm., xlvi. 325, 1843.

Like muscovite or common mica in crystallization, and in optical and other physical characters, except usually a more pearly lustre, and the color more commonly whitish or silvery.

Comp.—O. ratio mostly 1 : 6 : 9 : 2; whence the formula $(\frac{1}{3}(\dot{\mathrm{R}}^3, \dot{\mathrm{H}}^3)+\frac{2}{3}\ddot{\bar{\mathrm{A}}}\mathrm{l})^2\,\ddot{\mathrm{Si}}^3$, the water being basic. Sometimes O. ratio 1 : 9 : 12 : 2, whence, $(\frac{1}{4}(\dot{\mathrm{K}}^3, \dot{\mathrm{H}}^3)+\frac{3}{4}\ddot{\bar{\mathrm{A}}}\mathrm{l})^3\,\ddot{\mathrm{Si}}^3$; but this division belongs with damourite, if the two are distinguishable. This species appears to be often, if not always, a result of the hydration of muscovite, there being all shades of gradation between it and that species. Muscovite has the O. ratio for bases and silica of 4 : 5, or nearly; and the deficiency of base for a unisilicate here indicated appears to be the source of its tendency to take up water, the water passing in to supply it.

For analyses and localities see under MUSCOVITE (p 309).

A hydrous mica, accompanying cyanite, at Litchfield, Ct., afforded Smith & Brush (Am. J. Sci., II. xv. 210) $\ddot{\mathrm{Si}}$ 44·60, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 36·23, $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 1·34, $\dot{\mathrm{M}}\mathrm{g}$ 0·37, $\dot{\mathrm{C}}\mathrm{a}$ 0·50, $\dot{\mathrm{N}}\mathrm{a}$ 4·10, $\dot{\mathrm{K}}$ 6·20, $\dot{\mathrm{H}}$ 5·26, $\dot{\mathrm{M}}\mathrm{n}$, F *tr.*= 98·60. It is a *soda-potash* mica intermediate between margarodite and paragonite; O. ratio 1 : 7½ : 10 : 2; G.=2·76.

430. DAMOURITE. *Delesse*, Ann. Ch. Phys., III. xv. 248, 1845.

An aggregate of fine scales, mica-like in structure.

H.=2–3. G.=2·792. Lustre pearly. Color yellow or yellowish-white. Optic-axial divergence 10 to 12 degrees, Descl.

Comp.—A hydrous potash-mica, like margarodite, to which it is closely related. O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, 1 : 9 : 12 : 2.

Analyses: 1, Delesse (l. c.); 2, Igelström (B. H. Ztg., xxv. 308):

	$\ddot{\mathrm{Si}}$	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\ddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1. Pontivy	45·22	37·85	*tr.*	11·20	5·25=99·52 Delesse.
2. Horrsjöberg	43·41	35·17	4·62	10·90	4·50, $\dot{\mathrm{M}}\mathrm{g}$ 1·40=100 Igelström.

It is the gangue of cyanite at Pontivy in Brittany; and the same at Horrsjöberg, Wermland. Named after the French chemist Damour.

430A. SERICITE *List* (Ann. Ch. Pharm., lxxxi. 257). A scaly mineral from a silky schist, occurring at Nerothal near Wiesbaden. H.=1; G.=2·897; greenish or yellowish-white. It afforded List $\ddot{\mathrm{Si}}$ 49·00, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 23·65, $\dot{\mathrm{F}}\mathrm{e}$ 8·07, $\dot{\mathrm{M}}\mathrm{g}$ 0·94, $\dot{\mathrm{C}}\mathrm{a}$ 0·63, $\dot{\mathrm{N}}\mathrm{a}$ 1·75, $\dot{\mathrm{K}}$ 9·11, $\dot{\mathrm{H}}$ 3·41, $\ddot{\mathrm{T}}\mathrm{i}$ 1·39, Si F^2 1·60= 100·14. Supposed to be near damourite. Named from its silky lustre.

431. PARAGONITE. Paragonit *Schafhäutl*, Ann. Ch. Pharm., xlvi. 334, 1843. Pregrattit *L. Liebener*, Kenng. Ueb. 1861, 53, 1862.

Massive, sometimes consisting distinctly of fine scales; the rock slaty or schistose. Cleavage of scales in one direction eminent, mica-like.

H.=2·5–3. G.=2·779, paragonite, Schafhäutl; 2·895, pregrattite

Œllacher. Lustre strong pearly. Color yellowish, grayish, grayish-white, greenish, light apple-green. Translucent; single scales transparent.

Comp.—A hydrous *soda* mica. O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 9 : 12 : 2, or 1 : 1 for bases and silica, if the water be made basic. Formula $(\frac{1}{4}(\dot{\text{H}}^3, \dot{\text{N}}\text{a}^3)+\frac{3}{4}\bar{\text{Al}})^2\ddot{\text{Si}}^3$; the pregrattite has a little more of protoxyd bases, the O. ratio being 1 : 7·3 : 9 : 1·7=3 : 22 : 27 : 5, or nearly.

Analyses: 1, Schafhäutl (l. c.); 2, Rammelsberg (ZS. G., xiv. 761); 3, Œllacher (Kenng. Ueb. l. c.):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Fe}}$	$\dot{\text{M}}\text{g}$	$\dot{\text{C}}\text{a}$	$\dot{\text{N}}\text{a}$	$\dot{\text{K}}$	$\dot{\text{H}}$
1. *Paragonite*	50·20	35·90	2·36	—	—	8·45	—	2·45=99·36 Schafhaütl.
2. " (⅔)	46·81	40·06	*tr.*	0·65	1·26	6·40	*tr.*	4·82=100 Ramm.
3. *Pregrattite*	44·65	40·41	$\dot{\text{F}}\text{e}$ 0·84	0·37	0·52	7·06	1·71	5·04, $\bar{\text{Cr}}$ 0·10=100·70 Œllacher.

Pyr.—B.B. the paragonite is stated to be infusible. The pregrattite exfoliates somewhat like vermiculite (a property of some clinochlore and other species), and becomes milk-white on the edges.

Obs.—Paragonite constitutes the mass of the rock at Monte Campione, in the region of St. Gothard, containing cyanite and staurotide, called paragonitic or talcose schist. The rock also contains garnet and black tourmaline. Named from παράγω, *I mislead*. The pregrattite is from Pregratten in the Pusterthal, Tyrol.

A Brevig mica afforded Defrance 5 p. c. of soda, but with much less silica than above. See under LEPIDOMELANE, p. 307, where relations to other Brevig mica are stated, that tend to show that it is an altered mica.

432. EUPHYLLITE. *Silliman, Jr.*, Am. J. Sci., II. viii. 381, 1849.

Structure as in mica, but laminæ not as easily separable.

H.=3·5–4·5. G.=2·963–3·008, Silliman; 2·83, Smith & Brush. Lustre of cleavage surface bright pearly, inclining to adamantine. Color white to colorless; sides faint grayish sea-green or whitish. Transparent to translucent; at times opaque or nearly so. Laminæ rather brittle. Biaxial; angle between the optical axes 71½°, Silliman.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 8 : 9 : 2; whence $(\frac{1}{3}\dot{\text{R}}^3+\frac{2}{3}\bar{\text{R}})^2\ddot{\text{Si}}^3+\frac{2}{3}\dot{\text{H}}$=, if $\dot{\text{C}}\text{a}$: $\dot{\text{K}}$: $\dot{\text{N}}\text{a}$=3 : 4 : 11, Silica 41·6, alumina 42·3, lime 1·5, potash 3·2, soda 5·9, water 5·5=100. Analyses: Smith & Brush (Am. J. Sci., II. xv. 209):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Fe}}$	$\dot{\text{M}}\text{g}$	$\dot{\text{C}}\text{a}$	$\dot{\text{N}}\text{a}$	$\dot{\text{K}}$	$\dot{\text{H}}$
1. Unionville	40·29	43·00	1·30	0·62	1·01	5·16	3·94	5·00=100·32 Smith & Brush.
2. "	39·64	42·40	1·60	0·70	1·00	5·16	3·94	5·08=99·52 Smith & Brush.
3. "	40·21	41·50	1·50	0·78	1·88	4·26	3·25	5·91=99·29 Smith & Brush.
4. "	40·96	41·40	1·30	0·70	1·11	4·26	3·25	6·23=99·21 Smith & Brush.

The specimen for analysis 2 by Smith & Brush was from the original one described by Silliman. Their results show that the earlier analysis of Crooke (Am. J. Sci., II. viii. 381) and those of Erni & Garrett (this Min., 3d edit., 362, 1850) are erroneous. Erni's and Crooke's specimens were from the same that afforded the material for analysis 2 of Smith & Brush.

Pyr., etc.—In a matrass yields water. B.B. exfoliates, emits a strong light, and in the forceps fuses on the edges. Gives traces of fluorine.

Obs.—Occurs associated with tourmaline and corundum at Unionville, Delaware Co., Pa. The impression of the crystals of tourmaline on the lateral surface of the euphyllite leaves a very smooth, hard-looking surface. Also in the same vicinity in aggregated laminæ, or scales, or compact masses.

Dr. Smith refers here, with a query, a mica found by him with the emery of Asia Minor, which afforded him the following results (Am. J. Sci., II. xi. 62, xv. 210):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Fe}}$	$\dot{\text{M}}\text{g}$	$\dot{\text{C}}\text{a}$	$\dot{\text{K}}$, little $\dot{\text{N}}\text{a}$	$\dot{\text{H}}$
1. Gumuchdagh	42·80	40·61	1·30	*tr.*	3·01	*undet.*	5·62
2. Kulah	43·62	38·10	3·50	0·25	0·52	7·88	5·51
3. "	42·71	37·52	2·32	*tr.*	1·41	*undet.*	5·95
4. Nicaria	42·60	37·45	1·70	*tr.*	0·68	9·76	5·20

They afford the mean oxygen ratio, excluding the water, 1 : 10 : 12. May be *damourite*. A similar whitish mica, from Newlin, Pa., afforded S. B. Sharples $\ddot{Si}$ 43, $\bar{Al}$ 40, alk. 7 to 8 p. c.

433. ŒLLACHERITE.
Margarite from Pfitschthal *Œllacher*, Kenng. Uebers. 1860, 49, 1862. Œllacherite *Dana*, Am. J. Sci., II. xliv. 256, 1867.

In crystalline scales or laminæ; structure micaceous.

G.=2·884—2·994. Lustre strong pearly. Color grayish-white to white. In thin plates transparent. Elastic. Double refraction strong; optic-axial angle in the air 79° 21′ for the red ray, 78° 45′ for the blue, or the same as in muscovite; Descl.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}$, 1 : 4 : 6 : 1; whence the formula, if $\dot{H}$ be basic, $(\frac{1}{3}(\dot{R}^3, \dot{H}^3)+\frac{2}{3}\bar{Al})^2\ddot{Si}^3$. Remarkable for the presence of baryta. Analyses: 1, Œllacher (l. c.); 2, Rammelsberg (ZS. G., xiv. 763):

	$\ddot{Si}$	$\bar{Al}$	$\bar{Fe}$	$\dot{Fe}$	$\dot{Mn}$	$\dot{Cu}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{Ba}$	$\dot{Sr}$	$\dot{Na}$	$\dot{K}$	$\dot{H}$
1.	42·59	30·18	0·91	1·74	0·12	0·31	4·85	1·03	4·65	0·09	1·42	7·61	4·43=99·98 Œ.
2.	48·07	32·79	——	1·85	0·31	——	2·90	0·28	5·91	——	*undet.*		4·26 Ramm.

Obs.—Occurs near Kemmat in Pfitschthal, along with the chlorite analyzed by Hetzer (p. 502). The locality is about 12 miles in a direct line from that of margarite (p. 506).

434. COOKEITE.
G. J. Brush, Am. J. Sci., II. xli. 246, 1866.

In minute scales, and in slender six-sided prisms, sometimes vermicularly bent. Often as a coating.

H.=2·5. G.=2·70. Lustre pearly on plane of cleavage. Color white to yellowish-green. In thin scales transparent. Flexible, inelastic.

Comp. O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}$, 1·93 : 21 : 18·74 : 11·91, Brush=1 : 10 : 9 : 5½. Approaches a hydrous lithia mica in composition. Analysis: P. Collier (l. c.):

	$\ddot{Si}$	$\bar{Al}$	$\dot{Li}$	$\dot{K}$	$\dot{H}$	SiF^2
(½)	34·93	44·91	2·82	2·57	13·41	0·47, $\dot{H}$ exp. at 100°C. 0·38=99·49.

Three determinations of the silica obtained 35·04, 34·05, 35·71 p. c. The alumina contained a little oxyd of iron.

Pyr., etc.—B.B. exfoliates like vermiculite, and colors the flame intense carmine-red. In the closed tube yields water, which is at first neutral, then becomes acid by decomposing the fluorid of silicon evolved, while a ring of silica is deposited. Tube slightly etched. Fusible on thin edges, and gives blue color with cobalt solution. With phosphorus salt gives skeleton of silica. Partially decomposed by sulphuric acid.

Obs.—Occurs with tourmaline and lepidolite at Hebron and Paris, Me., often as a pearly coating on crystals of rubellite, of which it appears to be a product of alteration.

435. HISINGERITE.
Hisingerit (fr. Riddarhyttan) *Berz.*, Pogg., xiii. 505, 1828. Degeröit *Holmberg*, Bidr. Finl. Nat., i. 4, Min. Ges. St. Pet., 1850, 1851, N. Nordenskiöld, Verz. Finl. Min., 1852. Skotiolit *Arppe*, Finsk. Min., 13, 1857.

Amorphous, compact, without cleavage.

H.=3. G.=3·045. Lustre greasy, inclining to vitreous. Color black to brownish-black. Streak yellowish-brown. Fracture conchoidal.

Var.—(1) *Hisingerite.* (2) *Degeröite*, G.=2·54, Holmberg; H.=2·5; color blackish-green to black. (3) *Scotiolite*; G.=3·09; H.=3; color dark green to black (and named from *σκοτιος, dark*) contains much magnesia, and less water than hisingerite.

Comp.—O. ratio for $\dot{R}+\bar{R}$, $\ddot{Si}$, $\dot{H}$=2 : 3 : 3; formula, making one-third of the water basic, $(\dot{R}^3, \bar{R})^2\ddot{Si}^3+4aq$, or specially, $(\frac{1}{3}\dot{H}^3+\frac{2}{3}(\dot{R}^3.\bar{Fe}))^2\ddot{Si}^3+4aq$. In the latter formula $\dot{R}^3$ includes some

$\dot{\mathrm{F}}\mathrm{e}$, $\dot{\mathrm{M}}\mathrm{g}$, $\dot{\mathrm{C}}\mathrm{a}$, and occasionally $\dot{\mathrm{M}}\mathrm{n}$. Excluding $\dot{\mathrm{R}}$, the percentage composition is Silica 35·9, sesquioxyd of iron 42·6, water 21·5=100. Cleve's analysis makes the *scotiolite* of Longban essentially hisingerite · and that of Orijärvi may be an impure variety (anal. 15).

Analyses: 1, Haidinger (Pogg., xiii. 505); 2–11, Cleve, Oeberg, Lindström, Nordenskiöld, Thoreld (Œfv. Ak. Stockh, 1866, 169); 12, Rammelsberg (Pogg., lxxv. 398); 13, 14, Thoreld (Min. Ges. St. Pet., 1850, 51, Œfv. Ak. Stockh., 1866, 169); 15, Arppe (l. c.):

		$\ddot{\mathrm{S}}\mathrm{i}$	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\bar{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$

The part of the water driven off at 100° C. was in anal 2, 11·20; 4, 11·66; 5, 13·11; 6, 9·33; 7, 12·19; 8, 9·37; 9, 13·56; 10, 10·61; 11, 6·30; 14, 11·60; 15, 7·49.

Pyr., etc.—Yields much water. B.B. fuses with difficulty to a black magnetic slag. With the fluxes gives reactions for iron. In muriatic acid easily decomposed without gelatinizing.

Obs.—Found at the various localities mentioned above. At Riddarhyttan it occurs in reniform masses associated with pyrite in a copper mine, and is a result of alteration; at Degerö, near Helsingfors, Finland, in a silver mine.

Named after the Swedish chemist, Hisinger.

MELANOLITE *Wurtz* (this Min., 379, 1850). Approaches hisingerite. It is black, opaque, with streak dark olive-green; H.=2; G.=2·69. Surface of the mineral often striated, or with an imperfectly columnar aspect. H. Wurtz obtained, excluding 12·77 p. c. of carbonate of lime:

$\ddot{\mathrm{S}}\mathrm{i}$ 35·36 $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 4·49 $\bar{\mathrm{F}}\mathrm{e}$ 23·20 $\dot{\mathrm{F}}\mathrm{e}$ 25·18 $\dot{\mathrm{N}}\mathrm{a}$ 1·86 $\dot{\mathrm{H}}$ 10·24=100·33.

From Milk-Row quarry, near Charlestown, Mass., incrusting the sides of a fissure.

436. EKMANNITE. Ekmannit *L. J. Igelström*, Œfv. Ak. Stockh., 1865, B. H. Ztg., xxvi. 21, 1867.

Foliated, chlorite-like. Also foliated columnar and asbestiform, radiated; also granular massive, consisting of minute scales.

Hardness and lustre as in chlorite. Color grass-green, leek-green, grayish-white; also black.

Comp.—O. ratio for $\dot{\mathrm{R}}+\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=4 : 6 : 3, with the bases mainly *protoxyds* ($\dot{\mathrm{F}}\mathrm{e}$, $\dot{\mathrm{M}}\mathrm{n}$); only one-third to one-sixth being sesquioxyds ($\bar{\mathrm{F}}\mathrm{e}$, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$), and regarded as impurity by Igelström. Formula $(\frac{2}{3}(\dot{\mathrm{F}}\mathrm{e}, \dot{\mathrm{M}}\mathrm{n})+\frac{1}{3}\dot{\mathrm{H}})^2\,\ddot{\mathrm{S}}\mathrm{i}+\frac{1}{3}\dot{\mathrm{H}}$, in which two-thirds of the water is made basic. Analyses: 1–6, Igelström (l. c.):

		$\ddot{\mathrm{S}}\mathrm{i}$	$\ddot{\bar{\mathrm{A}}}\mathrm{l}$	$\bar{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$

---

[a] With perhaps some alumina.

Pyr., etc.—On heating yields water, becomes black, submetallic, and after ignition strongly magnetic. B.B. fuses to a black slag. Soluble in muriatic acid, with a deposition of silica.

Obs.—From a mine of magnetite at Grythyttan, in Sweden, filling cavities in the ore, penetrating it extensively, and constituting nodular masses and beds. Anal. 4 is of the green interior of a nodule which was black externally. Some of it contains carbonate of lime, and some affords when heated a bituminous odor.

Named after G. Ekmann, proprietor of the mine.

Alt.—Becomes black on exposure, through oxydation.

437. NEOTOCITE. Neotokit *N. Nordenskiöld*, Vers. Finl. Min., 1852. Wittingit *id.*, ib. Vattenhaltigt Manganoxid-silikat *J. F. Bahr*, Œfv. Ak., 1850, 240. Stratopeit *L. J. Igelström*, ib., 1851, 143 (with mention of "Neotokit" and "Wittingit").

Amorphous.

H.=3–4. G.=2·64–2·8. Lustre dull, sometimes feebly submetallic. Color black to dark brown and liver-brown. Streak dark brown to black. Opaque.

Comp., Var.—The amorphous mineral substances here included are results of the alteration of rhodonite, in which the manganese passes from the state of protoxyd to that of sesquioxyd, and other changes take place through the presence of any ingredients in the altering infiltrating waters. A uniformity of composition is not therefore to be expected, and much doubt must exist as to the reality of the species which any chemical analyses may seem to indicate. The most recent analyses (anal. 2 to 5 below) have a correspondence in oxygen ratio which appears to show that there is among them at least one true hydrous silicate of manganese, and that it is related in composition to hisingerite. The O. ratio for $\dot{R}+\bar{R}$, $\ddot{Si}$, $\dot{H}$, in analysis 2 is 12·69 : 19·11 : 14·32; 3, 11·56 : 18·69 : 14·86; 4, 12·11 : 19·09 : 14·02; 5, 13·04 : 18·34 : 15·44; each of which correspond quite nearly to 2 : 3 : 2½, and to the general hisingerite formula, $(\dot{R}^3, \bar{R})^2 \ddot{Si}^3+3$ aq, in which two-fifths of the water is made basic.

Neotocite (anal. 4, 5) is here included by A. E. Nordenskiöld along with stratopeite, and good authority appears thus to be given for setting aside the older analysis of it by Igelström (anal. 6). In *stratopeite*, G.=2·64, according to Igelström; in *neotocite* and *wittingite*, G.=2·7–2·8, according to N. Nordenskiöld.

Bahr's and Svanberg's analyses, 9–12, give a different composition, as the manganese is made sesquioxyd; but new determinations are required before these, or the analyses of wittingite, can be taken as representing distinct chemical compounds. Bahr writes for analyses 9, 10, 11, $\bar{Mn}^2 \ddot{Si}^3+3\dot{H}$; and for anal. 12, obtains the O. ratio for $\dot{R}+\bar{R}$, $\ddot{Si}$, $\dot{H}$, 13·9 : 17·6 : 8·5. The *wittingite* analyzed by Arppe (anal. 7) contained 7·21 p. c. of carbonic acid, corresponding to 18·82 p. c. of carbonate of manganese.

Analyses: 1, Igelström (l. c.); 2–5, Cleve and A. E. Nordenskiöld (Œfv. Ak. Stockh., 1866, 169, J. pr. Ch., c. 121); 6, Igelström (Nord. Verz. Finl. Min., 1852, Beskrifn. Finl. Min., 138, 1863); 7, Arppe (Finsk. Min., 21); 8, Nordenskiöld (J. pr. Ch., c. 122); 9–12, Bahr (l. c.):

Pyr., etc.—Yields much water. Reactions with borax for manganese and iron. Difficultly fusible to infusible.

Obs.—Occurs with rhodonite at Paisberg in Filipstad, Sweden (*stratopeite*); Gestrikland (*neotocite*) in Sweden; at Ingoa (*ib.*), Finland; at Wittingi (*wittingite*) in Storkyro, Finland; at Bredvik (*ib.*) in West Gothland; at Klapperud in Dalecarlia, Finland.

Named from νεοτοκος, *of recent origin*. This name antedates *stratopeite*.

438. STÜBELITE. Stübelit *Breith.*, B. H. Ztg., xxiv. 322, 1865.

Reniform and botryoidal massive.

H.=4—5. G.=2·223—2·263. Lustre vitreous, brilliant. Color velvet to pitchy black. Streak dark brown. Fracture conchoidal, distinct. Brittle. Analysis by Stübel (l. c.)

$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\dddot{\mathrm{A}}}\mathrm{l}$	$\bar{\dddot{\mathrm{F}}}\mathrm{e}$	$\bar{\dddot{\mathrm{M}}}\mathrm{n}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{H}}$	Cl
26·99	5·37	10·18	21·89	15·25	1·03	16·85	0·77=98·33.

OBS.—Occurs at the island of Lipari. Named from Dr. Alphonse Stübel.

439. GILLINGITE. Svart Stenart (fr. Gillinge) *Hisinger*, Afh., iii. 304, 1810. Gillingit *Hisinger*, Min. Geogr. Schwed. (Wöhler's), 102, 1826. Thraulit (fr. Bodenmais) v. *Kob.*, Pogg., xiv. 67, 1828. Traulit.

Amorphous—compact.

H.=3. G.=3·045, Hisinger, fr. Gillinge. Lustre shining to dull; surface of fracture earthy. Color black or blackish.

Comp., Var.—O. ratio for $\dot{\mathrm{R}}+\bar{\dddot{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=, nearly, 1 : 1 : 1; whence $(\dot{\mathrm{R}}^3, \bar{\dddot{\mathrm{R}}})^3 \ddot{\mathrm{S}}\mathrm{i}^3$+6 aq. (1) In anal. 3, of *gillingite*, $\dot{\mathrm{R}}^3 : \bar{\dddot{\mathrm{R}}}$=2 : 5; in 4, 7 : 9·5, or nearly 3 : 4. (2) For anal 7, of *thraulite*, v. Kobell adopts the same O. ratio, 1 : 1 : 1, observing that the mineral analyzed contained some mixed pyrrhotite Analyses: 1, Hisinger (Afh., iii. 304); 2, Rammelsberg (Pogg., lxxv. 398); 3, 4, Hoglund and Tamm (Œfv. Ak. Stockh., 1866, 169, J. pr. Ch., c. 128); 5, Hermann (J. pr. Ch., xlvi. 238); 6, Hisinger (Pogg., xiii. 505); 7, v. Kobell (l. c.):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\dddot{\mathrm{A}}}\mathrm{l}$	$\bar{\dddot{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$

7. " "	31·28	—	43·42	5·70	—	—	—	19·12=99·52 Kobell.

Pyr., etc.—Yields much water. B.B. fuses at 5 to a black, slaggy, opaque, magnetic globule. Decomposed by muriatic acid.

Obs.—From Gillinge-Grube, in Södermanland, Sweden, whence the name. *Thraulite* (named from θραυλός, *fragile*) occurs at Bodenmais, three leagues from Zwiesel, in Bavaria, with vivianite, etc.

440. JOLLYTE. Jollyt v. *Kobell*, Ber. Ak. München, 1865, 168.

Compact, amorphous.

H.=3. G.=2·61. Lustre weak greasy. Color dark brown; in thin splinters transparent, with green to brownish-red color; the coarse powder is light leek-green, the fine, light grayish-green; in some positions the powder appears ochre-yellow. Fracture subconchoidal and splintery. In thin splinters shows double refraction.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\dddot{\mathrm{R}}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=1 : 2 : 3 : 2; $(\frac{1}{3}\dot{\mathrm{R}}^3+\frac{2}{3}\bar{\dddot{\mathrm{A}}}\mathrm{l})^2 \ddot{\mathrm{S}}\mathrm{i}^3$+4 $\dot{\mathrm{H}}$, if $\dot{\mathrm{F}}\mathrm{e} : \dot{\mathrm{M}}\mathrm{g}$=3 : 2,= $\ddot{\mathrm{S}}\mathrm{i}$ 35·5, $\bar{\dddot{\mathrm{A}}}\mathrm{l}$ 27·0, $\dot{\mathrm{F}}\mathrm{e}$ 17·0, $\dot{\mathrm{M}}\mathrm{g}$ 6·3, $\dot{\mathrm{H}}$ 14·2=100. Analysis: v. Kobell (l. c.):

$\ddot{\mathrm{S}}\mathrm{i}$ 35·55 $\bar{\dddot{\mathrm{A}}}\mathrm{l}$ 27·77 $\dot{\mathrm{F}}\mathrm{e}$ 16·67 $\dot{\mathrm{M}}\mathrm{g}$ 6·66 $\dot{\mathrm{H}}$ 13·18=99·83.

Pyr., etc.—In the closed tube yields water. B.B. swells up and fuses with difficulty on thin edges to a black mass, which is not magnetic, or only slightly so; with the fluxes gives the reactions for iron. Decomposed readily by muriatic acid, leaving gelatinous silica.

Obs.—Occurs at Bodenmais in Bavaria, with pyrite, vivianite, iolite, etc. Resembles a hisingerite in which the iron is replaced by alumina. It is distinguished from this mineral, as well as from gillingite, by the green color of its powder, and by yielding a residue before the blowpipe which is but slightly magnetic. Named after the physicist, G. Jolly.

L. Sæmann observes, in a letter to the author, that this species is very similar to fahlunite.

441. EPICHLORITE *Ramm.* (Pogg., lxxiii. 437, 1849). Fibrous or columnar, between schiller spar and chlorite in its characters. H.=2—2·5; G.=2·76; color dull leek-green; streak white to greenish; lustre greasy; in thin columns translucent and of a bottle-green color.

COMP.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}$=4 : 3 : 9 : 4, whence, for bases, silica, and water, if half of the water be basic, 9 : 9 : 2. Analysis (l. c.):

$\ddot{Si}$ 40·88 $\bar{Al}$ 10·96 $\bar{Fe}$ 8·72 $\dot{Fe}$ 8·96 $\dot{Mg}$ 20·00 $\dot{Ca}$ 0·68 $\dot{H}$ 10·18=100·38.

B B. fuses only in thin fibres with difficulty. With the fluxes reaction of silica and iron.

Forms veins in a rock resembling serpentine at Harzburg. Named in allusion to its being near chlorite in characters.

442. POLYHYDRITE *Breith.* (Handb., ii. 334, 1841). From St. Cristoph, at Breitenbrunn, in Saxony. Amorphous; H.=2—3; G.=2·095—2·142; lustre dull; color liver-brown; streak lighter, grayish. According to Plattner, contains $\ddot{Si}$, $\bar{Fe}$, $\dot{Fe}$, with some $\bar{Al}$, $\dot{Mn}$, and 29·20 p. c. of water. In muriatic acid decomposed.

443. LILLITE *Reuss* (Ber. Ak. Wien, xxv. 550, 1857). From Przibram in Bohemia, with pyrite, and arising, apparently, through the agency of decomposing pyrite. H.=2; G.=3·043. Earthy, like glauconite; blackish-green. Analysis afforded $\ddot{Si}$ 32·48, $\bar{Fe}$, $\dot{Fe}$ 54·95, $\dot{H}$ 10·20, $\dot{Ca}\ddot{C}$ 1·96, Fe S 0·63=100·22.

444. CHLORITE-LIKE MINERAL, from the *keuper* of Altenburg, *Haushofer* (J. pr. Ch., xcix. 239). Color dark leek-green. Stated to be B.B. infusible. Analysis gave $\ddot{Si}$ 29·51, $\bar{Al}$ 11·54, $\bar{Fe}$ 18·26, $\dot{Fe}$ 25·26, $\dot{Ca}$ 0·52, $\dot{H}$ 14·81=99·90. O. ratio of bases and silica=1 : 1, and of $\dot{R}$, $\bar{R}$=1 : 2.

445. PYROSCLERITE. Pyrosklerit *v. Kobell*, J. pr. Ch., ii. 53, 1834.

Orthorhombic, or monoclinic; Descl. Cleavage: basal eminent or micaceous; in a transverse direction at right angles to the former, in traces. H.=3. G.=2·74, v. Kobell. Lustre of cleavage surface weak pearly. Color apple- to emerald-green. Translucent.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{Si}$, $\dot{H}$=4 : 2 : 6 : 3; whence $(\frac{2}{3}\dot{R}^3+\frac{1}{3}\bar{Al})^2\ddot{Si}^3+3\dot{H}$=Silica 38·9, alumina 14·8, magnesia 34·6, water 11·7=100. By making part of the water basic in this species and the three following, the O. ratio for bases and silica may be 3 : 2, and the formulas as written on p. 451.

Analysis: v. Kobell (l. c.):

	$\ddot{Si}$	$\bar{Al}$	$\bar{Cr}$	$\dot{Fe}$	$\dot{Mg}$	$\dot{H}$
1. Elba, *Pyrosclerite*	37·03	13·50	1·43	3·52	31·62	11·00=98·10.

The O. ratio from the analysis is 13·43 : 6·75 : 19·74 : 9·78, whence 20·18 : 19·74 for the bases and silica.

Pyr., etc.—Yields water. B.B. fuses at 3·8—4 to a grayish glass. With the fluxes reacts for chromium and iron. Decomposed by muriatic acid with gelatinization.

Obs.—Pyrosclerite appears to differ from kämmererite in crystallization as well as composition. It may include *tabergite* (p. 496, 7, 8) and the *Talc-chlorite* of Traversella (p. 500).

Occurs with chonicrite, constituting seams in serpentine, near Porto Ferrajo, Elba.

Named from πῦρ, *fire*, and σκληρός, *hard* (refractory).

445A. VERMICULITE *T. H. Webb* (Am. J. Sci., vii. 55, 1824). Hexagonal, being optically uniaxial, Descl. Occurs in small foliated scales, distributed through a steatitic base, and hence scaly-massive. H.=1—2; G.=2·756, Crossley; lustre somewhat talc-like; color grayish, somewhat brownish.

Analysis: Crossley (this Min., 3d ed., 291, 1850):

$\ddot{\mathrm{Si}}$ 35·74 $\overline{\mathrm{Al}}$ 16·42 $\dot{\mathrm{Fe}}$ 10·02 $\dot{\mathrm{Mg}}$ 27·44 $\dot{\mathrm{H}}$ 10·30=99·92.

O. ratio for $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=13·20 : 7·66 : 19·16 : 9·14=7 : 4 : 11 : 5, or approximately 4 : 2 : 6 : 2 which is that of pyrosclerite. General formula $(\dot{\mathrm{R}}^3, \overline{\mathrm{R}})^2 \ddot{\mathrm{Si}}^3$+2 aq, as above. Thomson obtained $\ddot{\mathrm{Si}}$ 49·08, $\overline{\mathrm{Al}}$ 7·28, $\overline{\mathrm{Fe}}$ 16·12, $\dot{\mathrm{Mg}}$ 16·96, $\dot{\mathrm{H}}$ 10·28; but he evidently took the specimen in mass, while Crossley separated with great care from the base the scaly mineral which is the true vermiculite. When heated exfoliates prodigiously, the scales opening out into long, worm-like threads, made up of the separate folia. Exfoliation commences at 500° to 600° F., and takes place with so much force as often to break the test tube in which the mineral may be confined. B.B. fuses at 3·5 to a grayish-black glass.

Occurs at Milbury, near Worcester, Mass. Named by Webb, as he says, from the Latin *vermiculor, I breed worms.*

446. CHONICRITE. Chonikrit *v. Kob.*, J. pr. Ch., ii. 51, 1834. Metaxoit *Arppe*, Finsk. Min., Act. Sci. Fenn., vi. 580, 1861, Holmberg, Verh. Min. St. Pet., 1862, 145.

Massive, crystalline granular, or compact; sometimes globular, radiated. H.=2·5–3. G.=2·91, v. Kob.; 2·58–2·61, Arppe. Lustre weak silky, to glimmering or dull. Color white, sometimes with yellowish or grayish spots; pale greenish-blue.

Comp., Var.—O. ratio for $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=3 : 2 : 5 : 2. It is a *lime* pyrosclerite. *Chonicrite* occurs only massive, white, with G.=2·91, and has the lime to the magnesia as 1 : 2. *Metaxoite* is greenish-blue to nearly white, amorphous or crystalline granular, with G.=2·58–2·61, and lime to magnesia about 1 : 1. It contains more silica, the oxygen ratio for bases, silica, and water being 5 : 6 : 3. Analyses: 1, v. Kobell (l. c.); 2–4, Asp and Hällsten (Finsk. Min., l. c.):

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\overline{\mathrm{Mn}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
1. *Chonicrite*	35·69	17·12	—	—	1·46	22·50	12·60	9·00=98·37 Kobell.
2. *Metaxoite, cryst.*	38·69	9·68	4·7	*undet.*	—	15·28	*undet.*	12·97 Asp.
3 " "	37·90	9·78	6·78	2·05	—	12·23	18·79	12·76=100·24 Asp.
4. " *amorph.*	40·63	10·17	6·78	*undet.*	—	11·24	16·08	12·88 Hällsten.

Chonicrite gives the O. ratio for $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=12·8 : 8 : 19·0 : 8; or for bases, silica, and water, 20·8 : 19 : 8.

Metaxoite, anal. 3, gives 10·3 : 7·17 : 20·21 : 11·84=for bases, silica, and water, 17·5 : 20·2 : 11·3.

Pyr., etc.—Yield much water. Chonicrite fuses with intumescence at 3·5–4 to a grayish-white glass, and is decomposed by muriatic acid, the silica separating in powder. Metaxoite acts much the same.

Obs.—Chonicrite forms, with pyrosclerite, seams in serpentine, on Elba; and metaxoite is found near Lupikko in Finland, some versts south of Pitkaranta, with serpentine.

Chonicrite is from χωνεία, *fusion*, and κριτός, *test*, its fusibility distinguishing it from some allied species. *Metaxoite*, from its nearness to *metaxite*.

447. JEFFERISITE. Vermiculite? *G. J. Brush*, Am. J. Sci., II. xxxi. 369, 1861; Jefferisite *id.*, ib., xli. 248, 1866.

Orthorhombic? In broad crystals or crystalline plates. Cleavage: basal eminent, affording easily very thin folia, like mica. Surface of plates often triangularly marked, by the crossing of lines at angles of 60° and 120°.

H.=1·5. G.=2·30. Lustre pearly on cleavage surface. Color dark yellowish-brown and brownish-yellow; light yellow by transmitted light. Transparent only in very thin folia. Flexible, almost brittle. Optically biaxial, Descl.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=2 : 3 : 5 : 2½ (in the analysis, 3); whence $(\frac{2}{5}\dot{\mathrm{R}}^3+\frac{3}{5}\overline{\mathrm{R}})^2 \ddot{\mathrm{Si}}^3$+3 $\dot{\mathrm{H}}$. Differs from pyrosclerite in the larger proportion of sesquioxyds. Analysis: Brush (l. c.)

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
Westchester	37·10	17·57	10·54	1·26	19·65	0·56	*tr.*	0·43	13·76=100·87 Brush.

The exact O. ratio is 8·20 : 11·36 : 19·79 : 12·23, giving for bases and silica 19·56 : 19·79.

Pyr., etc.—When heated to 300° C. exfoliates very remarkably (like vermiculite); B.B. in forceps after exfoliation becomes pearly-white and opaque, and ultimately fuses to a dark gray mass. With the fluxes reactions for silica and iron. Decomposed by muriatic acid.

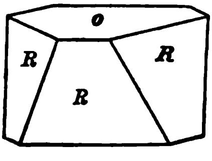
Obs.—Occurs in veins in serpentine at Westchester, Pa. Plates often several inches across Named after W. W. Jefferis of Westchester, Pa.

A foliated mineral similarly exfoliating occurs coarse-granular massive, according to R. Pumpelly, in Japan, in the mountains of the peninsula of Kadzusa, S.E. of Yedo.

A mineral from the Vosges, referred to pyrosclerite by Delesse (Ann. d. Min., IV. xx. 155, 1851). approaches more nearly the jefferisite in its oxygen ratio, although containing less oxyd of iron as a substitute for alumina. It has the following characters: cleavage as in pyrosclerite, perfect in one direction, and less so in a transverse; structure a little lamellar; soft; G.=2 622; lustre greasy or waxy; color grayish, bluish, and emerald-green. Composition. according to Delesse, $\ddot{\rm Si}$ 38·39, $\bar{\bar{\rm Al}}$ 26·54, $\bar{\bar{\rm Cr}}$ *tr.*, $\dot{\rm Fe}$ 0·59, $\dot{\rm Mn}$ *tr.*, $\dot{\rm Mg}$ [22·16], $\dot{\rm Ca}$ 0·67, $\dot{\rm H}$ 11·67. O. ratio for $\dot{\rm R}$, $\bar{\bar{\rm R}}$, $\ddot{\rm Si}$, $\dot{\rm H}$=2 : 3 : 5 : 2½. As the magnesia was not directly determined, the results are doubtful. It occurs in nodules in serpentine at St. Philippe, near Sainte Marie-aux-Mines.

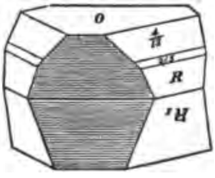
448. PENNINITE. Chlorite pt. Hydrotalc (=Wasserglimmer of Morin) *Necker*, Min., 1835 Pennine *J. Fröbel & E. Schweizer*, Pogg., l. 523, 1840. Kämmererite *Nordensk.*, Act. Soc. Sci. Fen., i. 483, 1841, and Arsberät. 1843, 193. Rhodochrom *Fiedler*, Rose, Reise n. d. Ural, ii 1842, and Pogg., lix. 1843. Tabergit pt. *Scheerer*, Pogg., lxxi. 448, 1847. Chromchlorit *Herm.*, J. pr. Ch., liii. 21, 1851. Rhodophyllite *Genth.*, Proc. Ac. Sci. Philad., 1852, 118, 121. Penninite *Dana.*

414



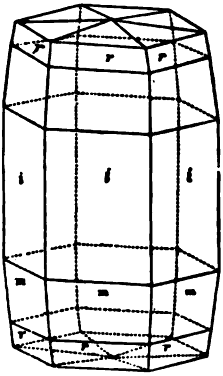
Texas, Pa.

415



Texas, Pa.

41



Kämmererite, Urals.

Rhombohedral. $R \wedge R$=65° 36′, $O \wedge R$=103° 55′; a=3·4951. Observed planes: O, i; rhombohedral, $\frac{4}{15}$, $\frac{2}{5}$, $\frac{7}{10}$, R, $\frac{5}{2}$ (r), $\frac{7}{2}$ (m), occurring often as pyramids, f. 416. $O \wedge \frac{4}{15}$=128° 51′; $O \wedge \frac{2}{5}$=121° 47′; $R \wedge \frac{2}{5}$=162° 8′; $O \wedge \frac{5}{2}$ (r)=95° 40′ (95° 16′ obs.); $O \wedge \frac{7}{2}$ (m)=94° 3′ (obs. 94° 0′); $R \wedge \underline{R}$, in twin,=152° 10′. Cleavage: basal, highly perfect. Crystals often tabular, and in crested groups. Also massive, consisting of an aggregation of scales; also compact cryptocrystalline.

H.=2—2·5; 3, at times, on edges. G.=2·6—2·85; 2·673, Ala. Lustre of cleavage surface pearly; of lateral plates vitreous, and sometimes brilliant. Color green, apple-green, grass-green, grayish-green, olive-green; also reddish, violet, rose-red, pink, grayish-red; occasionally yellowish and silver-white; violet crystals, and sometimes the green, hyacinth-red by transmitted light along the vertical axis. Transparent to subtranslucent. Laminæ flexible, not elastic. Double refraction feeble; axis either negative or positive, and sometimes positive and negative in different laminæ of the same plate or crystal.

Var.—1. *Penninite.* As first named, it included a green crystallized chlorite from the Pennine Alps.

Hydrotalc of Necker is penninite from the Binnen valley, in the Valais. Axis of double refraction positive, Descl. Most of the penninite from Zermatt, and that of Binnen and the Tyrol, have a negative optical axis; some crystals of Zermatt, and those of Ala, a positive, and some plates from Zermatt consist of positive and negative laminæ united; Descl.

2. *Tabergite*, from Taberg, Wermland (*Blue talc* of Werner, and called also *mica-chlorite*), is a bluish-green or green chlorite. According to Descloizeaux's optical observations, it is in part *uniaxial*, with the axis positive like true *penninite*. But in other cases uniaxial and biaxial plates are combined, and negative and positive also; and the axial divergence of the biaxial plates varies from 1° to 33°, indicating a mixture of penninite and another chlorite, either pyrosclerite or ripidolite.

Crystals of Texas have the double refraction positive though feeble (Descl., Cooke); they are often mixed with ripidolite, and sometimes a crystal is traversed by a band of ripidolite, whose optic-axial angle is 60° to 70° (Descl.).

3. *Kämmererite*. The original specimen was a reddish-violet micaceous mineral from L. Itkul in Bissersk, in Perm, Russia, partly in 6-sided prisms. It was named after Kämmerer of Russia. *Rhodophyllite* of Genth, and *chrom-chlorite* of Herm. (anal. 12), are the same, from Texas, Pa.; G.= 2·617—2·62. *Rhodochrome* is a compact or scaly-granular variety, originally from L. Itkul, Siberia, having a splintery fracture, with G.=2·66—2·67. Color deep green; but violet, rose- or peach-blossom-red in thin splinters, whence the name.

4. *Loganite* of Hunt (=*Pseudophite* of Kenngott) is near penninite in composition. A notice of loganite, from Calumet Falls, Canada, is given under *Altered Hornblende* (p. 242), as it has the form, angles, and cleavage of that species; and also of an allied material under *Altered Pyroxene* (p. 221). It has G.=2·60—2·64; color clove-brown to chocolate-brown; lustre dull.

Pseudophite of Kenngott (Ber. Ak. Wien, xvi. 1855) has the composition of loganite, but is compact massive, without cleavage, and resembles serpentine (whence the name, from ψευδός, *false*, and *ophite* or serpentine); H.=2·5; G.=2·75—2·77; lustre weak; color grayish-green, olive-green, pistachio-green; feel unctuous. It forms the gangue of enstatite ($\dot{Mg}\ddot{Si}$) at Zdjar in Aloysthal, Moravia. In the occurrence of a massive form, penninite is thus like talc, pyrophyllite, and other related species.

Descloizeaux found (Min., 436) $R \wedge R$=65° 28′ in penninite, and $O \wedge R$=103° 45′; and the latter in the Texas kämmererite. The above angles, and figs. 414, 415, are from Cooke's paper on the latter (Am. J. Sci., II. xliv. 201), and f. 416 is from Kokscharof (Verh. Min. Ges. St. Pet., 1851).

Comp.—O. ratio for bases and silica 4 : 3, corresponding to 8 ($\dot{Mg}^3$, $\overline{Al}$), 9 $\ddot{Si}$, 12 $\dot{H}$, but varying from 4 : 3 to 5 : 4. Exact deductions from the analyses cannot be made until the state of oxydation of the iron in all cases is ascertained; and, further, until it is also proved that there may not be a crystalline mixture such as is mentioned above under tabergite. The mineral often contains microscopic grains of magnetite, and these are supposed by Kenngott to occasion some of the discrepancies in the analyses.

Analyses: (1) *Penninite*. 1, Schweizer (Pogg., l. 526); 2, 3, Marignac (Ann. Ch. Phys., III. x. 428); 4, Merz (Kenngott's Uebers., 1858, 62); 5, MacDonnell (Proc. R. Acad. Dublin, 5, 307); 6, Marignac (l. c.); 7, Rammelsberg (4th Suppl., 87). (2) *Kämmererite, etc.* 8, Hartwall (Jahresb., xxiii. 266); 9, Hermann (J. pr. Ch., liii. 1); 10, T. H. Garrett (Am. J. In anal. 15, G.=2·63; 18, G.=2·383; 20, G.=2·355.

Tabergite afforded Svanberg (Ak. H. Stockholm, 155, 1839): S̈i 35·76, Äl 13·03, Ḟe 6·34, Ṁn 1·64, Ṁg 29·27, K̇ 2·07, Mg F 1·1, Ḣ 11·76=100·98. C. W. C. Fuchs obtained for its composition (Jahrb. Min. 1867, 822) S̈i 32·95, Äl 18·08, Ḟe 13·72, Ṁn 0·07, Ṁg 26·83, Ċa 0·95, Ḣ 11·34, K 0·33, Na 1·25, F 0·97=100·49; giving the O. ratio for Ṙ, R̈, S̈i, Ḣ=7 : 3 : 9 : 5, while the analysis of Svanberg gives 6 : 3 : 9 : 5; both of which are near that of *pyrosclerite*. G.=2·813. Des Cloizeaux refers a part of tabergite to ripidolite (see below).

Pyr., etc.—In the closed tube yields water. B.B. exfoliates somewhat and is difficultly fusible. With the fluxes all varieties give reactions for iron, and many varieties react for chromium. Partially decomposed by muriatic and completely by sulphuric acid.

Obs.—Occurs with serpentine in the region of Zermatt, Valais, near Mt. Rosa, especially in the moraines of the Findelen glacier; crystals from Zermatt are sometimes 2 in. long and 1½ in. thick; also at the foot of the Simplon; at Ala, Piedmont, with clinochlore; at Schwarzenstein in the Tyrol; at Taberg in Wermland; at Snarum, greenish and foliated, called *steatite of Snarum*.

Kämmererite is found at the localities already mentioned; also near Miask in the Urals; at Haroldswick in Unst, Shetland Isles. Abundant at Texas, Lancaster Co., Pa., along with clinochlore, some crystals being imbedded in clinochlore, or the reverse.

The union of kämmererite and penninite is made by Descloizeaux, and is sustained by his optical examinations, as well as by chemical composition.

449. DELESSITE. Chlorite ferrugineuse *Delesse*, Ann. d. M., IV. xii. 195, 1847, and xvi. 520, 1849. Delessite *Naum.*, Min., 1850. Eisenchlorit.

Massive, with a short fibrous or scaly feathery texture, often radiated.

H.=2·5. G.=2·89. Color olive-green to blackish-green. Powder gray or green.

Analyses: Delesse (l. c):

	S̈i	Äl	F̈e	Ḟe	Ṁg	Ċa	Ḣ
1. Mielen	31·07	15·47	17·54	4·07	19·14	0·46	11·55=99·30.
2. Oberstein	29·08	42·00		——	12·23	3·70	12·99=100
3. Zwickau	29·45	18·25	8·17	15·12	15·32	0·45	12·57=99·83.

Anal. 1 affords the O. ratio for Ṙ, R̈, S̈i, Ḣ=8·7 : 12·5 : 16·5 : 10·27; and anal. 3, 11·87 : 10·96 15·70 : 11·18. The former gives for the O. ratio of bases and silica 1 : 1·29, and the latter 1 : 1·45; the mean of which is about 3 : 4.

In a matrass yields water and becomes brown. B.B. fuses with difficulty on the edges. Easily soluble in acids, affording a deposit of silica.

Occurs coating or filling the cavities of amygdaloid, or amygdaloidal porphyry, at Oberstein, Zwickau, La Grève near Mielen.

Named after Delesse, of Paris.

450. RIPIDOLITE. Chlorite pt. *early authors* (for Syn., see p. 501). Hexagonal Chlorite pt. Ripidolith (fr. Achmatovsk, Schwarzenstein) *v. Kob.*, J. pr. Ch., xvi. 1839. ? Tabergit pt. H.=2—2·5. G.=2·65—2·78; 2·774, fr. Achmatovsk, G. Rose; 2·672, ib., Marignac; 2·603, ib., Hermann; 2·673, fr. Ala, Marignac; 2·714, fr. Texas, Blake; 2·71, fr. Willimantic, Burton. Lustre of cleavage-face somewhat pearly. Color deep grass-green to olive-green; also rose-red. Often strongly dichroic, being sometimes brownish or hyacinth-red transverse to the vertical axis, by transmitted light, when green in the direction of the axis; at other times green in both directions. Streak greenish-white to uncolored. Transparent to translucent. Flexible and somewhat elastic. Optic-axial divergence 10° to 86°; bisectrix acute positive, inclined 12° to 16° to the normal to O; plane in a direction either parallel (f. 422), or at right angles (f. 423) to two sides of the hexagonal base, the lines in f. 422, 423, and the lining in f. 420, 421 (of the twins), showing the two directions.

Var.—1. *Ordinary*; green ripidolite, passing into bluish-green and bluish (tabergite); (*a*) foliated; (*b*) massive. 2. *Kotschubeite*; rose-red. 3. *Exfoliating*, much like vermiculite. Descloizeaux found the optic-axial angle in the mineral from Texas 15°—60° (a crystal having a hexagonal nucleus of kämmererite); others from Pennsylvania 70°—86°; from Achmatovsk and Arendal, Norway, 40°—42°; fr. Zermatt, 46°; fr. Zillerthal, 48°—50°; fr. Pfunders, 46°—54°; fr. St. Gothard, fr. Cavalaire, Dept. of Var, 26°, 44°, 72°; fr. Pfitsch, Tyrol, 15°—38°; fr. Ala, 15°—42°; fr. la, 15°—24°; fr. Taberg (tabergite), bluish to green, 10°—83°. In a Pennsylvania plate 38° at 20° to 100° C.; 69° at 150° C.; 72° at 180° C.; 73½° at 190° C.; 75° at 205° C

Cooke found the angle for plates fr. Texas 67°—84°, with the inclination of the bisectrix 13½° to 15½°.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=5 : 3 : 6 : 4; corresponding to 5 $\dot{\mathrm{M}}\mathrm{g}$, $\bar{\mathrm{A}}\mathrm{l}$, 5 $\ddot{\mathrm{S}}\mathrm{i}$, 4 $\dot{\mathrm{H}}$=Silica 32·5, alumina 18·6, magnesia 36·0, water 12·9=100. 13. Willimantic, Ct.	31·86	15·80	—	4·77	—	34·30	12·72, $\dot{\mathrm{C}}\mathrm{a}$ 1·30=99·75 Burton.

Rammelsberg found 4·55 $\dot{\mathrm{F}}\mathrm{e}$ in the mineral from Achmatovsk. In anal 9, G.=2·615; 10, G.=2·673; 11, G.=2·672; 12, G.=2·603. Pearse found the green chlorite of Texas to contain (Am

J. Sci., II xxxvii. 222) $\ddot{S}i$ 28·62, $\ddot{\bar{A}}l$ 18·37, $\ddot{\bar{C}}r$ 1·97, $\dot{N}i$ 0·37, $\dot{F}e$ 3·73, $\dot{M}g$ 32·13, $\dot{C}a$ 1·45, $\dot{H}$ 14·02 =100·66; and on the ground of the low silica makes it a new species, and names it *grastite*, from γραστις, *grass.* The mineral was probably the true ripidolite of Texas, perhaps impure.

Pyr., etc.—Yields water. B.B. in the platinum forceps whitens and fuses with difficulty on the edges to a grayish-black glass. With borax, a clear glass colored by iron, and sometimes chromium. In sulphuric acid wholly decomposed. The variety from Willimantic, Ct., exfoliates in worm-like forms, like vermiculite.

Obs.—Occurs in connection with chloritic and talcose rocks or schist, and serpentine. Found at Achmatovsk and other foreign localities mentioned above; red (*kotschubeite*) in the district of Ufaleisk, Southern Ural; at Ala, Piedmont, with prochlorite; at Zermatt, with brown garnet; at Markt Leugast in Bavaria; Marienberg, Saxony.

In the U. States, in large crystals and plates at Westchester, in serpentine, and Unionville, Pa. (f. 424); at Texas, with chromite, and intimately associated, and sometimes compounded, with red and green penninite.

On cryst. see Kokscharof, Min. Russl., ii. 7 (abstract in Am. J. Sci., II. xix. 176); Descloizeaux, Min., i. 412; Hessenberg, Min. Not., No. vii. 28; J. P. Cooke, Am. J. Sci., II. xliv. 203, from whom figs. 420–423 are taken.

Named *ripidolite* from ῥιπις, *a fan*, in allusion to a common mode of grouping of the crystals; and *clinochlore*, from the inclined monoclinic form of crystallization ascertained by Blake's optical investigation. It has since been found, and first through examinations by Kokscharof, that the chlorite of Achmatovsk, and also that of Schwarzenstein and Ala, the three upon which von Kobell based his description of ripidolite, are also *monoclinic*, and identical with clinochlore. *Ripidolite* has nevertheless been, to some extent, set aside for *clinochlore*, because of the confusion in the science connected with that name (see p. 502); but the latter name is very objectionable, since there is now a second monoclinic chlorite known (p. 504). The former name is a register of von Kobell's important chemical discovery that the old chlorite included two distinct species (p. 502), and ought to be retained.

Talc-Chlorite of Traversella occurs in large hexagonal plates regularly grouped, and presents, according to Descloizeaux, the optical characters of clinochlore. The plates are twins, consisting of six triangular sections; at centre they are translucent and blackish-green, and have a *negative* bisectrix, and exteriorly clear green and transparent, with a *positive* bisectrix. Marignac regards it as between talc and chlorite. He obtained (Ann. Ch. Phys., III. xiv. 60, 1845):

	$\ddot{S}i$	$\ddot{\bar{A}}l$	$\dot{F}e$	$\dot{M}g$	$\dot{H}$
1.	38·45	11·75	12·82	28·19	8·49=99·70.
2.	39·81	12·56	11·10	28·41	7·79=99·67.
3.	41·34	11·42	10·09	29·67	7·66=100·18.

Corresponds nearly with the O. ratio 3 : 1 : 4 : 3, and therefore the general formula $(\dot{R}^3, \ddot{\bar{R}})^2$ $\ddot{S}i^3$+aq, or that of *pyrosclerite.* But it is possibly ripidolite impure from mixture with talc, which view would account for the high percentage of silica. Occurs at Traversella, Piedmont, with magnetite and ripidolite.

At Traversella there is still another *talc-chlorite*, soft and of a silvery-white lustre, having a single optical axis, or two very slightly divergent; the hexagonal plates are opaque at centre and transparent toward the borders. It affords much water in a matrass, and fuses with difficulty on the edges to a white enamel.

451. LEUCHTENBERGITE. Leuchtenbergit *Komonen*, Verh. Min. St. Pet., 1842, 64. Chlorite blanche de Mauléon *Delesse*, Ann. Ch. Phys., III. ix. 396, 1843.

Hexagonal. In hexagonal plates or crystals. Cleavage: basal eminent. H.=2·5. G.=2·61–2·71; 2·61–2·64, v. Leuchtenberg; 2·64–2·65, Kokscharof. Lustre of cleavage surface pearly. Colorless, white, yellowish-white, greenish-white; often opaque externally (from alteration) and colorless within. Translucent in thin laminæ when unaltered. Thin laminæ flexible, very slightly elastic. Optically unaxial; Haid., Descl.

Comp.—O. ratio for $\dot{R}$, $\ddot{\bar{R}}$, $\ddot{S}i$, $\dot{H}$=4½ : 3 : 5 : 3⅓; $(\frac{3}{5}\dot{M}g^3+\frac{2}{5}\ddot{\bar{A}}l)\ddot{S}i+1\frac{1}{3}\dot{H}$=Silica 30·4, alumina 20·9, magnesia 36·5, water 12·2=100. It is a prochlorite with the protoxyd base almost wholly magnesia. Analyses: 1, Hermann (J. pr. Ch., xl. 13); 2, v. Leuchtenberg (Bull. Ac. St. Pet., ix. 188); 3, Delesse (l. c.):

		Si	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
1. **Slatoust**		32·35	18·00	4·37	32·29	—	12·50=99·51 Hermann.
2. "	(½)	30·46	19·74	$\dot{\mathrm{Fe}}$ 1·99	34·52	0·11	12·74=99·56 Leuchtenberg.
3. **Mauléon**		32·1	18·5	0·6	36·7	—	12·1=100 Delesse.

Von Leuchtenberg's analysis was made on unaltered material, separated with great care, even microscopic, from impurities. It gives the O ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=18·83 : 9·85 : 16·24 : 11·32; and Hermann's, 12·92 : 10·69 : 17·26 : 11·11. The "white chlorite" of Mauléon appears to be identical with leuchtenbergite.

Pyr., etc.—In the closed tube yields water. B.B. exfoliates and fuses with difficulty on the thin edges, becoming white and opaque.

Obs.—Found in the Schischimsk Mts., near Slatoust, partly in large crystals, and partly quite small, imbedded in steatite. The crystals are mostly opaque and altered externally, and contain in this outer part from 9·30 to 10·75 p. c. of water. The mineral contains minute garnets and some other crystals as impurities.

Named after Duke N. v. Leuchtenberg.

452. PROCHLORITE. Mica pt., Telgsten pt.?, Lapis colubrinus lamellosus (fr. Salberg), *Wall.*, Min., 130, 1747. Talgsten pt., Specksten pt., *Cronst.*, Min., 89, 1758. Chlorit pt. (fr. Hexagonal? Cleavage: basal, eminent. Crystals often implanted by their sides, and in divergent groups, fan-shaped, or spheroidal. Also in large folia. Massive granular. H.=1—2. G.=2·78—2·96. Translucent to opaque; transparent only in very thin folia. Lustre of cleavage surface feebly pearly. Color green, grass-green, olive-green, blackish-green; across the axis by transmitted light sometimes red. Streak uncolored or greenish. Laminæ flexible, not elastic. Double refraction very weak; one optical negative axis (Dauphiny); or two very slightly diverging, apparently normal to plane of cleavage.

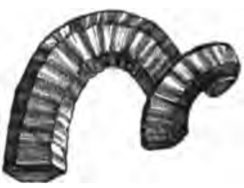
425



Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=12 : 9 : 14 : 9⅓; for bases and silica 3 : 2; $(\frac{1}{3}(\dot{\mathrm{Mg}}, \dot{\mathrm{Fe}})^3+\frac{2}{3}\bar{\mathrm{Al}})\ddot{\mathrm{Si}}+\frac{2}{3}\dot{\mathrm{H}}$=, if $\dot{\mathrm{Mg}}:\dot{\mathrm{Fe}}$=1 : 1, Silica 26·8, alumina 19·7, protoxyd of iron 27·5, magnesia 15·3, water 10·7=100. Analyses: 1, Varrentrapp; 2, Rammelsberg (Min. Ch., 538); 3, 4, v. Kobell (J. pr. Ch., xvi.); 5, Tschermak (Ber. Ak. Wien, liii. 26); 6, v. Kobell (l. c.); 7, 8, Marignac (Ann. Ch. Phys., III. xiv. 59); 9, Hermann; 10, J. L. Smith (Am. J. Sci., II. xi. 65); 11, Genth (Am. J. Sci., II. xxviii. 250); 12, Hisinger (Suckow, Erz. u. Gesteinlager schwed. Geb., 1831, 50); 13, Erdmann (Erdmann's Lärobok, 1853, 378):

Analyses 3, 4, are of the *lophoite* of Breithaupt; $R \wedge O$=105° 14′—105° 25′; G.=2·78—2·89 Analyses 1 and 6 are of his *ogcoite*.

The *helminthe* of Volger occurs in slender vermiform crystallizations like fig. 425 (whence the name), transversely foliated, penetrating quartz and feldspar. The figure is from a New Hampshire specimen described by O. P. Hubbard, and may be one of the other species of chlorite.

A dark green mineral from the Pfitschthal, accompanying Œllacher's margarite, afforded Hetzer (Ramm. Min. Ch., 845, ZS. Nat. Ver. Halle, v. 301) $\ddot{\mathrm{Si}}$ 28·04, $\dddot{\bar{\mathrm{Al}}}$ 23·19, $\dot{\mathrm{Fe}}$ 25·7, $\dot{\mathrm{Mg}}$ 15·68, $\dot{\mathrm{Ca}}$ 1·43, $\dot{\mathrm{H}}$ 2·30, F 0·98=97·32. It is stated to be infusible.

Pyr., etc.—Same as for ripidolite.

Obs.—Like other chlorites in modes of occurrence. Sometimes in implanted crystals, as at St. Gothard, enveloping often adularia, etc.; at Greiner in the Zillerthal, Tyrol; Rauris in Salzburg; Traversella in Piedmont; at Mtn. Sept Lacs in Dauphiny (anal. 7); in Styria; Bohemia. Also massive in Cornwall, in tin veins (where it is called *peach*); at Arendal in Norway; Salberg and Dannemora, Sweden; Dognacska, Hungary; also as pseudomorphs, at Bergmannsgrün, Saxony, after garnet, and at Greiner, Tyrol, after hornblende.

Grengesite from Grängesberg in Dalecarlia, Sweden (anal. 12), occurs partly in hexagonal crystallizations, more or less radiately grouped, and probably results, Erdmann observes (Lärobok Min., 1853, 374), from the alteration of pyroxene. Erdmann spells the name *Grängesite*. Specific gravity 3·1; color dark green. Reported also from Fischbachthal, as altered augite, in melaphyre.

Named from χλωρός, *green*.

Werner's species chlorite was shown to include more than one species by von Kobell in 1838, and the name *chlorite* was thereupon given by him to the St. Gothard and other chlorites having 25 to 27 p. c. silica, and *ripidolite* to that of Schwarzenstein and Achmatovsk having 30 to 33 p. c. of silica.

In 1839, G. Rose reversed the names of v. Kobell (see paper on chlorite by Varrentrapp, Pogg., xlviii. 198, 1839) on the ground that v. Kobell's *ripidolite* was not so characteristically fan-shaped in aggregation as the other species. But the change was unfortunate, as both species are now known to differ but little in this respect, and it has resulted in much confusion in the science. Moreover, it violated an older claim of priority; for Werner's *blättriger Chlorit* (or *Chlorites lamellosus*), the first crystallized chlorite recognized by him (in 1800 or earlier, Ludwig's Min., i. 118, 1803), was the hexagonal chlorite of St. Gothard, and this should therefore, in the division, have retained the name *chlorite*.

As the term *chlorite* has become the designation of a family of minerals, it seems necessary that it should have some modified form for this species, and hence the application of *prochlorite*, from πρό, *before*, and *chlorite*, in allusion to its being the earliest crystallized kind recognized.

The following are chlorite-like minerals of doubtful nature:

453. A CHLORITE-LIKE mineral from Webster, N. C., in crystals, micaceous in structure, of a dark bluish to brownish-green color, afforded Genth (Am. J. Sci., II. xxxiii. 200):

$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dddot{\bar{\mathrm{Cr}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Ni}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
31·45	13·08	4·16	4·88	0·16	43·10	0·17	0·06	3·29=100·35.

The ratio between the oxygen of the bases and silica is about 3 : 2. It is remarkable for the small amount of water and iron, and the large proportion of magnesia; a constitution which may have an explanation in its being a mixture of talc and chlorite. It is associated with a talc which Genth found to be nearly anhydrous (p. 453).

454. APHROSIDERITE *Sandberger* (Ueb. Geol. Nassau, 97, 1847). A soft ferruginous chlorite, of a dark olive-green color, scaly massive in structure; the scales minute, transparent, and hexagonal, and having G.=2·8 and H.=1; from Weilburg, Duchy of Nassau, at the Gelegenheit mine. A similar mineral, but more magnesian, has been found in gneiss at Guistberg in Wermland; in hematite at Bonscheuer near Muttershausen, Duchy of Nassau, having G.=2·991; at Balduinstein on the Lahr; and in mica schist with hematite at several places in Upper Styria, consisting of microscopic scales of a clear green color. Analyses: 1, Sandberger (loc. cit.); 2, J. Igelström (J. pr. Ch., lxxxiv. 480); 3, Erlenmeyer (Jahresb., 1860, 773); 4, v. Hauer:

	$\dddot{Si}$	$\dddot{\bar{Al}}$	$\dddot{\bar{Fe}}$	$\dot{Fe}$	$\dot{Mg}$	$\dot{H}$
1. Weilburg	26·45	21·25	——	44·24	1·06	7·74=100·74 Sandberger.
2. Guistberg	25·0	20·6	——	32·0	14·3	7·6=99·5 Igelström.
3. Bonscheuer	25·72	20·69	4·01	27·79	11·70	10·05=99·96 Erlenmeyer.
4. Styria	26·08	20·27	——	32·91	10·00	10·06=99·32 Hauer.

Anal. 1 corresponds nearly to $\dot{Fe}^3 \dddot{Si}+\dddot{\bar{Al}} \dddot{Si}+2 \dot{H}$. The others have part of the iron replaced by magnesia, and approach ordinary prochlorite.

455. **Metachlorite** *List* (ZS. G., iv. 684, 1852). Foliated columnar, like chlorite, vitreous to pearly in lustre, dull leek-green color. H.=2·5. Composition according to K. List (l. c.):

$\dddot{Si}$	$\dddot{\bar{Al}}$	$\dot{Fe}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{K}$	$\dot{Na}$	$\dot{H}$
23·77	16·48	40·36	3·10	0·74	1·37	0·08	13·75=99·60.

Whence the oxygen ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{Si}$, $\dot{H}$, is very nearly 4½ : 3 : 5 : 5, which gives for the oxygen of the bases and silica the ratio 7½ : 5=3 : 2, as in aphrosiderite.

B.B. fuses on the edges to a dark enamel. Gelatinizes in the cold with muriatic acid. Forms small veins in a green rock at Büchenberg near Elbingerode, in the Harz.

Baltimorite. "Baltimorite," so called from Baltimore, afforded v. Hauer (Jahrb. G. Reichs., 1853) $\dddot{Si}$ 27·15, $\dddot{\bar{Al}}$ 18·54, $\dot{Ca}$ 15·08, $\dot{Mg}$ 26·00, $\dot{H}$ 13·28=100. Hermann found in "Baltimorite" of a bluish color, $\dddot{Si}$ 33·26, $\dddot{\bar{Al}}$ 7·23, $\dddot{\bar{Cr}}$ 4·34, $\dot{Fe}$ 2·89, $\dot{Mg}$ 38·56, $\dot{H}$ 12·44, $\ddot{C}$ 1·30. Thomson, who instituted the species, found for it the composition essentially of serpentine (see p. 467). It is a good example of the indefinite mixtures that exist among the serpentine and allied minerals, and of the uncertainty as to the value of a species that is based on only one or two analyses of the specimens of a region, and especially on specimens received from ordinary collectors.

Prasilite *T. Thomson* (Phil. Mag., III. xvii. 416, 1840). A leek-green fibrous mineral, soft as Venetian talc, from Kilpatrick Hills, the fibres loosely cohering, with G.=2·311. Stated to consist of silica, magnesia, sesquioxyd of iron and alumina, with probably soda, and 18 p. c. of water. Analysis not given. Probably a chlorite of some kind.

455A. **Dumasite** *Delesse* (Dufr. Min., iii. 790, 1847, iii. 286, 1859). A chlorite lining cavities or fissures in certain melaphyres in the Vosges; color green; soft, and somewhat resembling ripidolite.

456. CRONSTEDTITE.

Cronstedtit *Steinmann*, Schw. J., xxxii. 69, 1821. Chloromelan *Breith.*, Char., 33, 184, 1823.

Rhombohedral. Occurs in hexagonal prisms, tapering toward the summit, or adhering laterally, and vertically striated; also in fibrous diverging groups, cylindroidal and reniform; also amorphous. Cleavage: basal, highly perfect.

H.=3·5. G.=3·348. Lustre brilliantly vitreous. Color coal-black to brownish-black. Streak dark olive-green. Opaque. Not brittle. Thin laminæ elastic.

Comp.—O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{Si}$, $\dot{H}$=3 : 3 : 4 : 3; whence (½ $(\dot{Fe}, \dot{Mn})^3$+½ $\dddot{\bar{Fe}}$) $\dddot{Si}$+¾ $\dot{H}$, from Damour's analysis. Analyses: 1, Steinmann (l. c.); 1A, same, as corrected by v. Kobell, after a determination of the degree of oxydation of the iron (Schw. J., lxii. 196); 2, second anal. of Steinmann, altered to correspond with the $\dddot{\bar{Fe}}$ in Damour's anal (Am. J. Sci., II. xxxi. 359); 3, Damour (Ann. Ch. Phys., III. lviii. 99):

	$\dddot{Si}$	$\dddot{\bar{Fe}}$	$\dot{Fe}$	$\dot{Mn}$	$\dot{Mg}$	$\dot{H}$
1. Przibram	22·452	——	58·852	5·078	2·885	10·700=99·968 Steinmann.
1A. "	22·452	35·350	27·112	5·078	2·885	10·700=103·577 Steinmann, altered.
2. "	22·83	29·08	31·44	3·43	3·25	10·70=100·73 Steinmann, altered.
3. "	21·39	29·08	33·52	1·01	4·02	9·76=98·78 Damour. G.=2·35.

Pyr., etc.—B.B. froths and fuses on the edges, yielding in R.F. a magnetic gray or black globule. With borax gives reactions for iron and manganese. Gelatinizes in concentrated muriatic acid.

Obs.—Accompanies limonite and calcite in veins containing silver ores at Przibram in Bohemia. Occurs also at Wheal Maudlin in Cornwall, in diverging groups.

Named after the Swedish mineralogist and chemist, A. Fr. Cronstedt.

456A. SIDEROSCHISOLITE *Wernekink* (Pogg., i. 387, 1824). Probably cronstedtite. Rhombohedral, affording the planes *O*, *I*, 1; crystals minute and often hemispherically grouped; cleavage, basal, perfect; also massive. H.=2·5; G.=3—3·4. Lustre splendent; color pure velvet-black when crystallized, dark greenish-gray; streak leek-green, greenish-gray; opaque.

Formula: $\dot{\mathrm{Fe}}^4\,\ddot{\mathrm{Si}}+1\frac{1}{2}\,\dot{\mathrm{H}}$, Wernekink, from an analysis of only three grains of the mineral (l. c.)

$\ddot{\mathrm{Si}}$ 16·3 $\dddot{\bar{\mathrm{Al}}}$ 4·1 $\dot{\mathrm{Fe}}$ $\dddot{\bar{\mathrm{Fe}}}$ 75·5 $\dot{\mathrm{H}}$ 7·3=103·2.

B.B. easily fusible, according to Wernekink (infusible, Berzelius); gelatinizes in muriatic acid It occurs in cavities in pyrrhotite and siderite, at Conghonas do Campo, Brazil.

457. CORUNDOPHILITE. *Shepard* (fr. N. Car.), Am. J. Sci., II. xii. 211, 1851; (fr. Chester, Mass.) *id.*, ib., xl. 112, 1865. Clinochlore (fr. Chester) *J. P. Cooke*, Am. J. Sci., II. xliv. 206, 1867.

Monoclinic, Descl. Form double hexagonal pyramids. Cleavage eminent, as in clinochlore. Twins common, like those of clinochlore (p. 498, f. 421).

H.=2·5. G.=2·90, fr. Chester, Brush. Lustre of cleavage surface somewhat pearly. Color olive-green, leek-green, grayish-green. Transparent to nearly opaque. Laminæ flexible, somewhat elastic. Optically biaxial; angle between the axes varies from a very small angle to 73½°, mostly 30° to 73½°; bisectrix positive, oblique to plane of cleavage; double refraction strong.

Var.—Descloizeaux found the optic-axial angle in a plate from Chester, Mass. (letter to the author of Jan. 1866), 65°, with an increase of 3° in the angle on heating to 200° C., a character which, he observes, distinguishes this mineral and ripidolite from penninite. Cooke found (l. c.) for the same, from different plates, the angles 32°, 45°, 71½°, 73½°. The plane of the axes perpendicular to two sides of the hexagon.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, fr. Pisani, 1 : 1 : 1 : ⅚, and between bases and silica 2 : 1; whence $(\frac{1}{2}\,\dot{\mathrm{R}}^3+\frac{1}{2}\,\dddot{\bar{\mathrm{Al}}})^4\,\ddot{\mathrm{Si}}^3+5\,\dot{\mathrm{H}}$. Analyses: 1, Pisani (Am. J. Sci., II. xli. 394); 2, J. L. Smith, "on material not absolutely pure" (ib., xlii. 92):

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$
1. Chester, Mass.	24·0	25·9	14·8	22·7	11·9, $\dot{\mathrm{Mn}}$, $\dot{\mathrm{Ca}}$, $\dot{\mathrm{Li}}$ *tr.*=99·3 Pisani.
2. " "	25·06	30·70	16·50	16·41	10·62=99·29 Smith.

Dr. C. T. Jackson found in the Chester chlorite (Proc. N. H. Soc., Boston, x. 321) $\ddot{\mathrm{Si}}$ 22·50, $\dddot{\bar{\mathrm{Al}}}$ 23·50, $\dddot{\bar{\mathrm{Fe}}}$ 41·50, $\dot{\mathrm{Mg}}$ 1·80, $\dot{\mathrm{H}}$ 11·00=100·30. It contained, he observes, some mixed magnetite. But it is further evident that nearly all the magnesia was left unseparated from the iron.

Obs.—Occurs with corundum or emery; its low percentage of silica accords with this association. The species was instituted on a chlorite found with the corundum of Asheville, N. C., whence the name, from corundum, and φιλος, *friend*. The above description is from specimens occurring abundantly, and sometimes in large and small crystals, at the emery mine of Chester, Mass., which Shepard has referred to corundophilite; its identity with the Asheville mineral is not yet ascertained. Shepard describes the latter (l. c.) as occurring in monoclinic crystals, with $I \wedge I$=120°, $O \wedge I$=97° 30′, $O \wedge i\text{-}i$=88° to 89°; sometimes in stellate groups; thin laminæ flexible; and he obtained in a very unsatisfactory chemical examination of 0·146 grain, $\ddot{\mathrm{Si}}$ 34·75, $\dddot{\bar{\mathrm{Al}}}$ 8·55, $\dot{\mathrm{Fe}}$ 31·25, $\dot{\mathrm{H}}$ 5·47, with a loss of 20 p. c.

458. CHLORITOID. Chloritspath *Fiedler*, Pogg., xxv. 329, 1832. Chloritoid *G. Rose*, Reis. Ural, i. 252, 1837. Barytophyllit *Glock.*, Grundr., 570, 1839. Masonite *C. T. Jackson*, Rep. G. of R. Island, 88, 1840. Sismondine *Delesse*, Ann. Ch. Phys., III. ix. 385, 1843.

Monoclinic, or triclinic. $I \wedge I'$ about 100°; O (or cleavage surface) on lateral planes 93°—95°, Descl. Cleavage: basal perfect; parallel to a lateral plane imperfect. Usually coarsely foliated massive; folia often curved or bent, and brittle; also in thin scales or small plates disseminated through the containing rock.

H.=5·5—6. G.=3·5—3·6 Color dark gray, greenish-gray, greenish-black, grayish-black, often grass-green in very thin plates; strongly dichroic. Streak uncolored, or grayish, or very slightly greenish. Lustre of surface of cleavage somewhat pearly. Brittle. Double refraction feeble; bisectrix oblique to the base; axial divergence small.

Var.—1. The original *chloritoid* (or chloritspath) from Kossoibrod, near Katharinenburg in the Ural, is in large curving laminæ or plates, grayish to blackish-green in color, often spotted with yellow from mixture with limonite; G.=3·55, Fiedler, 3·557, Breith.

2. The *Sismondine* or St. Marcel mineral is black; but, according to Descloizeaux, grass-green when in very thin laminæ parallel to *O*, pale green and black in two different directions at right angles to this; it has $I \wedge I$=about 100°, $O \wedge I$=93°; bisectrix negative; G.=3·565, Delesse.

3. *Masonite*, from Natic, R. I., is in very broad plates of a dark grayish-green color, but bluish-green in very thin laminæ parallel to *O*, and grayish-green at right angles to this; G.=3·529, Kenngott; $O \wedge I$, plane of cleavage, =95°, Descl. It is evidently impure, and this must have been especially true of the material analyzed by Jackson (anal. 12).

The Canada mineral is in small plates, one-fourth in. wide and half this thick, disseminated through a schist (like phyllite), and also in nodules of radiated structure, half an inch through; G.=3·513, Hunt. That of Gumuch-Dagh resembles sismondine, is dark green in thick folia and grass-green in very thin; G.=3·52, Smith.

Comp.—O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{S}i$, $\dot{H}$=1 : 3 : 2 : 1, for most analyses; whence the formula $(\frac{1}{2}(\dot{F}e, \dot{M}g)^3 + \frac{1}{2}\bar{A}l)^4 \ddot{S}i^3 + 3\dot{H}$=Silica 24·0, alumina 40·5, protoxyd of iron 28·4, water 7·1. The Pregratten mineral contains one-third less water ($2\dot{H}$).

Analyses: 1, Bonsdorff (G. Rose, Reis. Ural, i. 252); 2, v. Kobell (J. pr. Ch., lviii. 40); 3, Hermann (ib., liii. 18); 4, 5, O. L. Erdmann (ib., iv. 127, vi. 89); 6, Gerathewohl (ib., xxxiv. 454); 7, v. Kobell (Gel. Anz. München, Apr., 1854); 8, Delesse (Ann. Ch. Phys., III. ix. 385); 9, Kobell (J. pr. Ch., lviii. 39); 10, J. L. Smith (Am. J. Sci., II. xi. 64); 11, J. D. Whitney (Proc. N. H. Soc., Boston, 1849, 100); 12, C. T. Jackson (Rep. G. R. I., 88, 1840); 13, T. S. Hunt (Am. J. Sci., II. xxxi. 442):

13. Leeds, Canada	26·30	37·10	——	25·92	3·66	6·10, Mn 0·93=101·01 Hunt.

Erdmann, who made the earliest analysis, and also Gerathewohl (who made his examination on the same specimen, and under Erdmann's direction), obtained no water, and Hermann observes that the specimen had probably been calcined, as it is the custom to burn the emery rock at the locality in the Urals.

A green chlorite-like mineral, in fine scales, occurring in a quartz geode in the Spirifer sandstone in the vicinity of Ems, in Nassau, afforded Herget (Jahresb., 1863, 820):

$$\ddot{S}i\ 22·26 \qquad \bar{A}l\ 31·76 \qquad \dot{F}e\ 36·97 \qquad \dot{H}\ 8·63=99·62.$$

Giving the O. ratio for $\dot{R}$, $\bar{R}$, $\ddot{S}i$, $\dot{H}$=8 : 14 : 11 : $7\frac{1}{3}$, and corresponding to $(\frac{4}{11}\dot{F}e^3 + \frac{7}{11}\bar{A}l)^4 \ddot{S}i^3 + 4\dot{H}$. If a little of the iron is sesquioxyd, the composition may be the same as for chloritoid.

Pyr., etc.—In a matrass yields water. B.B. nearly infusible; becomes darker and magnetic. Completely decomposed by sulphuric acid. The masonite fuses with difficulty to a dark green enamel.

Obs.—The Kossoibrod chloritoid is associated with mica and cyanite; the St. Marcel occurs in a dark green chlorite schist, with garnets, magnetite, and pyrites; the Rhode Island, in an argillaceous schist; the Chester, Mass., in talcose schist, with emery, diaspore, etc.; the Canada, at Brome, in micaceous schist, and at Leeds in argillaceous schist. Chloritoid occurs also at Pregratten, in Tyrol; at Gumuch-Dagh, Asia Minor, with emery; in Saasthal, Valais.

Named *Chloritoid* from the resemblance to chlorite. The name *Chloritspath*, or in English *Chlorite Spar*, has the precedence in time. But it is objectionable in form and signification, and has rightly been superseded by chloritoid.

458A. PHYLLITE *Thomson* (Ann. Lyc. N. Y., iii. 47, 1828. Ottrelite *Descl. & Damour*, Ann. d. M., IV. ii. 357, 1842. Newportite *Totten*, Shepard's Min., i. 161, 1857). Phyllite (and ottrelite) closely resembles chloritoid, as observed by Hunt (Am. J. Sci., II. xxxi.), and also by Descloizeaux (Min., i. 466). The analyses hitherto made, however, show a wide discrepancy. Yet it should be noted on this point that we have only one of each variety, and the mineral is so involved in the containing slate rock that it is very difficult to obtain it pure.

Occurs in small, oblong, shining scales or plates, more or less hexagonal, in argillaceous schist. According to Descloizeaux, ottrelite is probably monoclinic, and the optical axes are very divergent. H=5–5·5; G. of ottrelite 4·4. Color blackish-gray, greenish-gray, black; streak grayish, greenish.

Analyses: 1, Thomson (l. c.); 2, Damour (l. c., 357):

	$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{Fe}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
1. Sterling, *Phyllite*	38·40	23·68	17·52	——	8·96	6·80	4·80=100·16 Thomson.
2. Ottrez, *Ottrelite*	43·34	24·63	——	16·72	8·18	——	5·66=98·53 Damour.

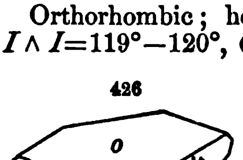
Yields water in the closed tube. Difficultly fusible to a magnetic globule. Reactions for iron with the fluxes.

Phyllite occurs in the schist of Sterling, Goshen, Chesterfield, Plainfield, etc., in Massachusetts, and Newport, R. I., and the rock in consequence of it is called by Hitchcock (Rep. G. Mass., 4to, 594, 1841) "Spangled Mica Slate," the phyllite being the mica of the schist. The scales are from $\frac{1}{8}$–$\frac{1}{4}$ in. long, and half to one-third this broad. Ottrelite is from a similar rock near Ottrez, on the borders of Luxembourg, and from Ardennes. Phyllite has also been reported from Tuscany. Descloizeaux remarks on the close resemblance of the ottrelite of Ardennes to the Newport phyllite, and Hunt on the same to the Canada chloritoid.

459. MARGARITE. Perlglimmer (fr. Sterzing) *Mohs*, Char., 1820, Grundr., 232, 1824. Margarite *Tyrolese min. dealers*. Corundellite (fr. Pa.), Clingmanite (fr. N. C.), *Silliman, Jr.*, Am. J. Sci., II. viii. 380, 383, 1849. Emerylite (fr. Asia Minor) *Smith*, ib., viii. 378, 1849, xi. 59, 1851.

Orthorhombic; hemihedral, with a monoclinic aspect, like muscovite. $I \wedge I$=119°–120°, $O \wedge r$=152°–153°, $O \wedge t$=144°–145°, $O \wedge s$=129°–134°, $O \wedge i\text{-}\breve{i}$=90°. Lateral planes horizontally striated. Cleavage: basal, eminent. Twins: common, composition-face I, and forming, by the crossing of 3 crystals, groups of 6 sectors. Usually in intersecting or aggregated laminæ; sometimes massive, with a scaly structure.

426



H.=3·5–4·5. G.=2·99, Hermann. Lustre of base pearly, laterally vitreous. Color grayish, reddish-white, yellowish. Translucent, subtranslucent. Laminæ rather brittle. Optic-axial angle very obtuse, 109° 32′, 117° 30′, 126° 24′, 128° 48′, for the red ray in different plates; plane of axes parallel to the longer diagonal; dispersion feeble.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$=1 : 6 : 4 : 1; whence, if the water be basic, for bases and silica=2 : 1; formula $(\frac{1}{3}(\dot{\text{R}}^3, \dot{\text{H}}^3)+\frac{2}{3}\bar{\text{Al}})^4\ddot{\text{Si}}^3$=Silica 30·1, alumina 51·2, lime 11·6, soda 2·6, water 4·5

Analyses: 1–9, J. L. Smith (Am. J. Sci., II. xi 59, and xv. 208); 10–13, W. J. Craw (ib., viii. 379); 14, B. Silliman, Jr. (this Min., 1850, 362); 15, W. J. Craw (ibid.); 16, C. [a] 0·05 of this is K O. [b] Trace of K O.

Pyr., etc.—Yields water in the closed tube. B.B. whitens and fuses on the edges.

Corundellite and *clingmanite* were based on an incorrect determination of the silica in the analyses.

Diphanite of Nordenskiöld (Bull. Ac. St. Pet., v. 17) is only margarite. It occurs in hexagonal prisms with perfect basal cleavage. H.=5—5·5. G.=3·04—3·97. Color white to bluish. Analysis by Jevreinof: $\ddot{\mathrm{Si}}$ 34·02, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 43·33, $\dot{\mathrm{C}}\mathrm{a}$ 13·11, $\dot{\mathrm{F}}\mathrm{e}$ 3·02, $\dot{\mathrm{M}}\mathrm{n}$ 1·05, $\dot{\mathrm{H}}$ 5·34=99·87.

Obs.—Margarite occurs in chlorite from the Greiner mount, near Sterzing in the Tyrol, where first found (f. 426); at different localities of emery in Asia Minor and the Grecian Archipelago, as discovered by Dr. Smith; with corundum at Village Green, Delaware Co., Pa.; at Unionville, Chester Co., Pa. (corundellite); at the corundum locality in Buncombe Co., North Carolina (clingmanite); with the corundum of Katharinenburg, Urals. It occurs massive in Pennsylvania. *Diphanite* is from the emerald mines of the Ural, with chrysoberyl and phenacite.

Named *Margarite* from μαργαρίτης, *pearl*. The name is attributed to Fuchs, but he nowhere published it. Von Leonhard (Handb., 1826, 766) gives it as "the current name among the Tyrolese dealers in minerals."

This species, according to Dr. Krantz (Am. J. Sci., II. xliv. 256), is the *original* margarite. The specimen from Sterzing analyzed by Smith & Brush was one received so labelled from Dr. Krantz of Bonn.

EPHESITE *J. L. Smith*, Am. J. Sci., II. xi. 59, 1851. Lamellar, and resembles white cyanite. Cleavage difficult. Scratches glass easily. G.=3·15—3·20. Color pearly-white.

Analysis by Smith (l. c.):

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{N}}\mathrm{a}$, little $\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	31·54	57·89	1·89	1·34	4·41	3·12=100·19.
2.	30·04	56·45	2·11	1·00	4·41	3·09=97·07.

The oxygen ratio deduced for the protoxyds, sesquioxyds, silica, and water, is 1 : 15 : 9 : 2. From the emery locality of Gumuch-Dagh, near Ephesus, on specimens of magnetite. Probably related to margarite, near which it is placed by Dr. Smith.

460. THURINGITE. Thuringit *Breith.*, Char., 95, 1832. Owenite *Genth*, Am. J. Sci., II. xvi. 1853.

Massive; an aggregation of minute scales; compact. Cleavage of scales distinct in one direction.

H.=2·5. G.=3·186, fr. Saalfeld, Smith; 3·151—3·157, id., Breith.; 3·197, owenite, Genth; 3·191, id., Smith. Lustre of scales pearly; of mass glistening or dull. Color olive-green to pistachio-green. Streak paler. Fracture subconchoidal. Very tough. Feel of powder greasy.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$=2 : 3 : 3 : 2; whence, if half the water is basic, $(\frac{1}{2}(\dot{\mathrm{R}}, \dot{\mathrm{H}})^3 + \frac{1}{2}(\dddot{\bar{\mathrm{A}}}\mathrm{l}, \dddot{\bar{\mathrm{F}}}\mathrm{e}))^4 \ddot{\mathrm{Si}}^3 + 4\dot{\mathrm{H}}$.

Analyses: 1, Rammelsberg (Min. Ch., 851); 2, J. L. Smith (Am. J. Sci., II. xviii. 376); 3, 4, P. Keyser (ib., 411); 5, 6, J. L. Smith (l. c.):

	$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\mathrm{A}}\mathrm{l}$	$\bar{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$

5. "	23·58	16·85	14·33	33·20	1·52	0·46	*tr.*	10·45, $\dot{\mathrm{M}}\mathrm{n}$ 0·09=100·48 Smith
6. Arkansas	23·70	16·54	12·18	33·14	1·85	0·32		10·90=99·74 Smith.

Pyr., etc.—In the closed tube yields water. B.B. fuses at 3 to an iron-black magnetic globule. With the fluxes reacts for iron. Gelatinizes with muriatic acid.

Obs.—Thuringite is from Reichmannsdorf (anal. 1, 2) and Schmiedeberg (anal 3), near Saalfeld, in Thuringia; Hot Springs, Arkansas (anal. 6); owenite from the metamorphic rocks on the Potomac, near Harper's Ferry.

Owenite was named after the geologist, Dr. D. D. Owen.

461. SEYBERTITE. Bronzite (fr. Amity) *J. Finch*, Am. J. Sci., xvi. 185, 1829. Clintonite (fr. Amity) *Mather*, 1828, but unpublished; Mather's Rep. G. of N. Y., 467, 1843. Seybertite (fr. Amity) *Clemson*, Ann. d. M., III. ii. 493, 1832, Am. J. Sci., xxiv. 171, 1833. Clintonit *im Handel* [=of the trade], Chrysophan (fr. Amity) *Breith.*, Char., 92, 1832. Holmite (fr. Amity) *Thomson*, Rec. Gen. Sci., iii. 335, 1836. Xanthophyllit *G. Rose*, Pogg., l. 654, 1840, Reis. Ural, ii. 120, 514, 527. Brandisit *Liebener*, in Haid. Ber., i. 4, 1846. Disterrit *Breith.*, in v. Kobell, J. pr. Ch., xli. 154, 1847.

Orthorhombic. $I \wedge I = 120°$. In tabular crystals, sometimes hexagonal; also foliated massive; sometimes lamellar radiate. Cleavage: basal perfect. Structure thin foliated, or micaceous parallel to the base.

H.=4—5. G.=3—3·1. Lustre pearly submetallic. Color reddish-brown, yellowish, copper-red. Streak uncolored, or slightly yellowish or grayish. Folia brittle. Double refraction strong; axial divergence 15° to 30° for white light; sometimes apparently uniaxial, or united at the ordinary temperature; bisectrix negative, normal to the base; axial plane parallel to i-$\bar{i}$; Descl.

Var.—1. The Amity *seybertite* (called also *clintonite*, *holmite*, and *chrysophan*) is in reddish-brown to copper-red brittle foliated masses; the surfaces of the folia often marked with equilateral triangles like some mica and chlorite; optic-axial divergence very small, or none at the ordinary temperature. G.=3·148, Brush.

2. *Xanthophyllite*, fr. the Schischimskian Mts., near Slatoust, is in crusts, or in implanted globular forms, 1¼ in. through, which consist of tabular crystals about a centre of talcose schist, which is also the enclosing rock. Optically uniaxial; axis negative, or two axes very slightly divergent, and hardly separating with increase of temperature; Descl.

3. *Brandisite* (called also *disterrite*), from Fassa, Tyrol, is in hexagonal prisms of a yellowish-green or leek-green color to reddish-gray; H.=5 of base; of sides, 6—6·5; G.=3·042—3·051, v. Kobell; 3·013—3·062, v. Hauer; 3·01—3·06, Liebener; optic-axial divergence 15° to 30°. Some of it pseudomorphous, after fassaite.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$, from Brush's analysis, =6 : 9 : 5 : ½; whence for $\dot{\mathrm{R}}+\bar{\mathrm{R}}$, $\ddot{\mathrm{S}}\mathrm{i}$=3 : 1, and formula $(\frac{2}{5}\dot{\mathrm{R}}^3+\frac{3}{5}\bar{\mathrm{A}}\mathrm{l})^2\ddot{\mathrm{S}}\mathrm{i}+\frac{1}{3}\dot{\mathrm{H}}$. From v. Kobell's (anal. 9), O. ratio for $\dot{\mathrm{R}}+\bar{\mathrm{R}}$: $\ddot{\mathrm{S}}\mathrm{i}$ the same, or 3 : 1, with $\dot{\mathrm{R}}^3$: $\bar{\mathrm{R}}$=1 : 1. From Meitzendorff's, O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\ddot{\mathrm{S}}\mathrm{i}$, $\dot{\mathrm{H}}$=12 : 20 : 9 : 2½; and for $\dot{\mathrm{R}}+\bar{\mathrm{R}}$, $\ddot{\mathrm{S}}\mathrm{i}$=3½ : 1. The state of oxydation of the iron was not examined except in the analysis by Brush.

Analyses: 1, Clemson (l. c.); 2, Richardson (Rec. Gen. Sci., May, 1836); 3, 4, G. J. Brush (this Min., 1854, 505); 5, Plattner (Breith. Handb., ii. 385); 6–8, Meitzendorf (Pogg., lviii. 165); 9, v Kobell (l c.)

9. Fassa, *Disler.*	20·00	43·22	$\dddot{\bar{\text{Fe}}}$ 3·60	25·01	4·00	—	3·60, $\dot{\text{K}}$ 0·57=100 Kobell.

Pyr., etc.—Yields water. B.B. infusible alone, but whitens. In powder acted on by concentrated acids.

Obs.—*Seybertite* occurs in limestone with serpentine, associated with hornblende, spinel, pyroxene, graphite, etc.; *xanthophyllite* in talcose schist; *brandisite* in white limestone, either disseminated or in grouped crystals, in geodes, among crystals of fassaite and black spinel.

The seybertite was discovered in 1828 by Messrs. Fitch, Mather, and Horton, and named *clintonite* by them on the spot, after De Witt Clinton, as stated by Mather in his Rep. Geol. N. Y., 1843. But the name was not published at the time by either of the discoverers; and Finch, the next year, 1829 (l. c.), announced the mineral under the name of *bronzite*. Clemson's name *seybertite*, after H. Seybert (1832, l. c.), has therefore priority of publication, and must be accepted as the name of the species.

APPENDIX TO HYDROUS SILICATES.

462. WOLCHONSKOITE. *Kämmerer*, Jahrb. Min., ii. 420, 1831.

Amorphous. Dull—shining. Color bluish-green, passing into grass-green. Streak bluish-green and shining. Feel resinous. Polished by the nail. Fracture subconchoidal. Adheres slightly to the tongue. Very fragile. H.=2·25. G.=2·2–2·3.

Comp.—O. ratio for bases, silica, and water (anal. 2, 4) 2 : 3 : 3, as in deweylite and genthite. Analyses: 1, Berthier (Mem., ii. 263); 2, Kersten (Pogg., xlvii. 489); 3, Ilimoff (Ann. Jour. Mines de Russie, 1842, 366); 4, Ivanof (Koksch. Min. Russl., i. 145):

	$\ddot{\text{Si}}$	$\dddot{\bar{\text{Al}}}$	$\dddot{\bar{\text{Cr}}}$	$\dddot{\bar{\text{Fe}}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{H}}$
1. Ochansk	27·2	—	34·0	7·2	—	7·2	23·2=98·8 Berthier.
2. "	37·01	6·47	17·93	10·43	1·66	1·91	21·84, $\dot{\text{Pb}}$ 1·01, $\dot{\text{K}}$ *tr.*=98·26 Kersten.
3. "	36·06	3·09	31·24	9·39	—	6·50	12·40, $\dot{\text{Ca}}$ 1·90, $\dot{\text{Pb}}$ 0·16=100·74 Ilimoff.
4. "	36·84	3·50	18·85	17·85	—	—	22·46, $\dot{\text{Ca}}$ 1·39=100·89 Ivanof.

Pyr., etc.—In the closed tube yields water. B.B. blackens, but is infusible. With the fluxes gives reactions for chromium and iron. Gelatinizes with hot concentrated muriatic acid, in which half the chromium is dissolved, the rest remaining in union with silica.

Obs.—From Okhansk in Siberia.

Named after M. Wolchonsky, of Russia.

463. **Selwynite**, *Ulrich* (Laboratory, i. 237, 1867). Massive. H.=3·5. G.=2·53. Emerald-green. Subtranslucent. Fracture uneven and splintery. Somewhat brittle.

Composition, according to an analysis by Mr. Cosmo Newbery:

$$\ddot{\text{Si}}\ 47{\cdot}15 \qquad \dddot{\bar{\text{Al}}}\ 38{\cdot}23 \qquad \dddot{\bar{\text{Cr}}}\ 7{\cdot}62 \qquad \dot{\text{Mg}}\ 4{\cdot}56 \qquad \dot{\text{H}}\ 6{\cdot}23=98{\cdot}78.$$

Corresponds to the O. ratio for $\dot{\text{R}}$, $\dddot{\bar{\text{R}}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$, 1 : 10 : 16½ : 3; or for bases and silica about 2 : 3; but probably a mixture. Perhaps containing some talc as impurity, with which it is traversed in thin seams. B.B. becomes white and fuses on the edges to a grayish-white blebby glass. Only partially soluble in strong acids.

Found near Heathcote, Victoria (Australia), in the Upper Silurian. Named after A. C Selwyn, director of the geological survey of Victoria.

464. *Chrome Ochre.* A clayey material, containing some oxyd of chrome. Occurs earthy of a bright green shade of color.

Analyses: 1, Drappiez; 2, Duflos (Schw. J., lxii. 251); 3, Zellner (Isis, 1834, 637):

	$\dddot{Si}$	$\dddot{\overline{Al}}$	$\dddot{\overline{Cr}}$	$\dddot{\overline{Fe}}$	$\dot{H}$
1. Creuzat, Fr.	64·0	23·0	10·5	—	—, $\dot{Ca}$ and $\dot{Mg}$ 2·5=100 Drappiez.
2. Halle	57·0	22·5	5·5	3·5	11·0=99·5 Duflos.
3. Silesia	58·50	30·00	2·00	3·00	6·25=99·75 Zellner.

The formula $(\dddot{\overline{Al}}, \dddot{\overline{Cr}}, \dddot{\overline{Fe}})^2 \dddot{Si}^3$ corresponds nearly to the composition, the water excepted.

Chrome ochre occurs at the localities above mentioned; also on Unst in Zetland, Mortenberg in Sweden, and elsewhere.

The *chrome ochre* of Halle, analyzed by Wolff (J. pr. Ch., xxxiv. 202), approaches selwynite in composition, but contains much more water. It afforded $\dddot{Si}$ 46·11, $\dddot{\overline{Al}}$ 30·53, $\dddot{\overline{Cr}}$ 4·28, $\dddot{\overline{Fe}}$ 3·15, $\dot{H}$ 12·53, $\dot{Na}$ 0·46, $\dot{K}$ 3·44=100·49; G.=2·7, giving rather closely the formula of kaolin, and may be an impure kaolinite.

465. MILOSCHITE. Miloschin *Herder*, Pogg., xlvii. 485, 1839. Serbian *Breith.*, J. pr. Ch., xv. 327, 1838.

Compact. H.=1·5—2. G.=2·131, Breith. Color indigo-blue to celandine-green.

COMP.—Approaches $(\dddot{\overline{Al}}, \dddot{\overline{Cr}}) \dddot{Si} + 3\ \dot{H}$, it being a *chromiferous allophane* with half the water of allophane. Analyses: 1, Kersten (Pogg., xlvii. 485); 2, Bechi (Am. J. Sci, II. xiv. 62):

	$\dddot{Si}$	$\dddot{\overline{Al}}$	$\dddot{\overline{Cr}}$	$\dot{Ca}$	$\dot{Mg}$	$\dot{H}$
1. Rudniak	27·50	45·01	3·61	0·30	0·20	23·30=99·92 Kersten.
2. Tuscany	28·36	41·33	8·11	—	—	22·75=100·55 Bechi.

In a matrass yields water. B.B. infusible. Partly dissolved in muriatic acid.

From Rudniak in Servia, associated with quartz and brown iron ore; Volterra, Tuscany.

Named after Prince Miloschi.

466. PIMELITE. Grüner Chrysopraserde (fr. Kosemütz) *Klapr.*, Schrift., Ges. N. Berlin, viii. 17, 1788, Beitr., ii. 134, 1797. Pimelit *Karst.*, Tab., 28, 72, 1800.

Massive or earthy. H.=2·5. G.=2·23—2·3; 2·71—2·76, Baer. Lustre weak, greasy. Color apple-green Streak greenish-white. Translucent to subtranslucent. Feel greasy. Does not adhere to the tongue.

COMP.—Analyses: 1, Klaproth (Beitr., ii. 134); 2, W. Baer (J. pr. Ch., lv. 49):

	$\dddot{Si}$	$\dddot{\overline{Al}}$	$\dddot{\overline{Fe}}$	$\dot{Ni}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{H}$
1. *Chrysoprase earth*	35·00	5·00	4·58	15·63	1·25	0·42	38·12 Klaproth.
2. *Hard Pimelite*	35·80	23·04	$\dot{Fe}$ 2·69	2·78	14·66	—	31·03=100 Baer.

Pimelite gives water in the closed tube, is infusible B.B., and with the fluxes reacts for nickel. Decomposed by acids.

From Silesia and elsewhere. Named from πιμελή, *fatness.* For Glocker's *alipite* see p. 404.

467. CHLOROPHÆITE. *Macculloch*, Western Isles, i. 504, 1825.

Granular massive, imbedded, or as a coating in geodes, fissures, or amygdaloidal cavities. Cleavage in two directions.

H.=1·5—2. G.=2·02, Macculloch; 1·809, Forchhammer. Lustre subresinous, rather dull. Color dark green, olive-green, changing to dark brown or black on exposure.

Formula perhaps $\dot{Fe}\ \dddot{Si} + 6\ \dot{H}$?=Silica 33·3, protoxyd of iron 26·7, water 40·0=100.

Analysis by Forchhammer (J. pr. Chem., xxx. 399, 1843): From Faröe, $\dddot{Si}$ 32·85, $\dot{Fe}$ 21·56, $\dot{Mg}$ 3·44, $\dot{H}$ 42·15=100, the iron being corrected (Rammelsberg) for the true atomic weight. B.B. fuses to a black glass.

A chlorite-like mineral from the Western Isles of Scotland, at Scuir More in the island of Rum, and from Fifeshire, occurring in amygdaloid; also from Qualböe and Suderöe, Faröe Islands. Reported also as incrusting chalcedony in Antrim, and in small botryoidal groups in amygdaloid at Down Hill. But the chemical identity of the original chlorophæite of Macculloch from Scuir More with that of Faröe or the other localities has not yet been ascertained. Named from χλωρός, *green*, and φαιός, *brown.*

468. KLIPSTEINITE. Schwarz-Braunsteinerz von Klapperud *Klapr.*, Beitr., iv. 137=Opsimose *Bud.*, Tr., 187, 1832. Vattenhaltigt Manganoxidsilikat *Bahr*, Œfv. Ak. Stockh., 1850. 242 Klipsteinite *v. Kob.*, J. pr. Ch., xcvii. 180.

Amorphous. Compact.
H.=5–5·5. G.=3·5. Lustre dull to submetallic. Color dark liver-brown to black. Streak reddish-brown or yellowish-brown. Opaque.

COMP.—O. ratio for $\dot{\mathrm{R}}+\bar{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$, doubtful; perhaps for klipsteinite 9 : 6 : 3, whence $(\dot{\mathrm{R}}^3, \bar{\mathrm{R}})^2\ddot{\mathrm{Si}}^3+\bar{\mathrm{R}}^3\dot{\mathrm{H}}^3$. Perhaps only a mixture.

Analyses: 1, Klaproth (l. c.); 2, Bahr (l. c.); 3, v. Kobell (l. c.):

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\bar{\mathrm{Mn}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$	
1. Klapperud, *Opsim.*	25	——	——	60	——	——	——	13	=98 Klaproth.
2. "	23·69	0·61	9·14	56·21	——	0·39	0·50	9·51	=100·05 Bahr.
3. Dillenburg, *Klipst.*	25·00	1·70	4·00	32·17	25·00	2·00	——	9·00	=98·87 Kobell.

PYR., ETC.—Yields much water. Fuses to a slag which is black in the oxydation flame. Gives reactions for manganese and iron. Easily decomposed by muriatic acid, the klipsteinite and Bahr's mineral evolving chlorine.

OBS.—From Klapperud in Dalecarlia with rhodonite; also from the Bornberg mine at Herborn, near Dillenburg.

Beudant's name *opsimose* has the priority, but is intolerable. It is from the Greek ὄψιμος, *doing anything late.* Klipsteinite was given after Prof. v. Klipstein of Giessen.

469. CHAMOISITE. Mine de fer oxydé en grains agglutinés *Gueymard*, J. d. M., xxxv. 29, 1814; Chamoisite *Berthier*, Ann. d. M., v. 393, 1820. Minerai de fer en grains *Berthier*, Ann. Ch. Phys., xxxv. 258, 1827. Berthierine *Beud.*, Tr., 128, 1832. Bavalite *Huot*, Min., 290, 1841.

Chamoisite occurs compact or oolitic, with H. about 3; G.=3–3·4; color greenish-gray to black; streak lighter; opaque; feebly attracted by a magnet. *Berthierine* is similar in structure, has H.=2·5; color bluish-gray, blackish, or greenish-black; streak dark greenish-gray; and strongly attracted by the magnet.

Analyses: 1, Berthier (l. c.); 2, id. (Ann. Ch. Phys., xxxv. 258, 1827):

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{H}}$	
1. *Chamoisite*	14·3	7·8	60·5	17·4	=100 Berthier.
2. *Berthierine*	12·4	7·8	74·7	5·1	=100 Berthier.

Chamoisite fuses easily, and also gelatinizes Berthierine fuses with difficulty to a black magnetic globule, and gelatinizes. The latter is mixed with 50 p. c. or more of siderite and calcite; Berthier found 40·3 of the former in the material he examined.

Chamoisite forms thick beds of rather limited extent in a limestone containing ammonites, at Chamoison, near St. Maurice, in the Valais; and a similar substance is reported from Mettenberg in the Bernese Oberland, and Banwald in the Vosges. *Berthierine* constitutes a valuable bed of iron ore at Hayanges, Dept. of Moselle, and also occurs in the ores of Champagne, Bourgogne, Lorraine.

470. ALVITE. *D. Forbes & T. Dahll*, Nyt. Mag., xiii.

Tetragonal Crystals like those of zircon.
H.=5·5. G.=3·601–3·46. Lustre greasy. Color reddish-brown, becoming grayish-brown by alteration. Subtranslucent to opaque.

COMP.– A very small portion, somewhat altered, afforded (l. c):

$\ddot{\mathrm{Si}}$ 20·83 $\bar{\mathrm{Al}}$, $\bar{\mathrm{Be}}$ 14·11 $\bar{\mathrm{Fe}}$ 9·66 $\dot{\mathrm{Zr}}$ 3·92 $\dot{\mathrm{Th}}$ (?) 15·18 $\bar{\mathrm{Ce}}$ 0·27 $\dot{\mathrm{Y}}$ 22·01 $\dot{\mathrm{Ca}}$ 0·40 Cu, Sn *tr.* $\dot{\mathrm{H}}$ 9·32=97·24

PYR., ETC.—Yields water. B.B. infusible; with the fluxes reacts for iron but not for titanium Insoluble in acids.

OBS.—From Helle and Narestö in Norway, with feldspar and black mica.

470A. PICROFLUITE. *Arppe*, Act. Soc. Fenn., vi.; Verh. Min. St. Pet., 1852, 148.

Amorphous. Lustre greasy to dull. Color white, inclining to yellow and blue. H.=2·5 G.=2·74.

COMP.—Probably a mixture of fluorite with a magnesian silicate. Analyses: 1, Galindo (l. c. 2, Arppe (l. c.):

	$\ddot{Si}$	$\dot{Fe}$	$\dot{Mn}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{H}$	F
1. Lupikko	29·00	1·54	0·78	28·79	22·72	8·97	11·16=102·96.
2. "	32·16	3 50	——	25·19	19·86	9·08	*undet.*

PYR., ETC.—B.B. fuses easily with intumescence. Completely soluble in acids; evolves fluoric of silicon with sulphuric acid.

OBS.—Occurs at Lupikko in Finland, some versts south of Pitkaranta, with chalcopyrite and blende.

---

[a] Without the oxygen [b] Id., and with some Li. [c] Later made to consist of 14·68 columbic acid and 46·15 hypocolumbic acid. [d] With thoria. [e] With protox. of uranium. [f] Fe^2O^3. [g] Ce^2O^3.

Pyr., etc.—Pyrochlore from the Miask gives but traces of water in the closed tube. B.B. infusible, but turns yellow and colors the flame reddish-yellow. When ignited it glows momentarily as if taking fire, the same phenomenon as observed with gadolinite. With borax and salt of phosphorus in both flames gives a light green bead, becoming colorless on cooling. A saturated bead of borax gives a greenish-gray enamel in R.F., while that with salt of phosphorus is reddish-gray. Decomposed by concentrated sulphuric acid with evolution of. fluorine (G. Rose). Pyrochlore from Norway gives water in the closed tube, and B.B. fuses with difficulty to a dark brown slaggy mass. With borax in R.F. gives a dark red bead, which by flaming turns to a grayish-blue to pure blue enamel. Dissolved with effervescence in salt of phosphorus, giving in O.F. a yellow bead while hot, becoming grass-green on cooling (uranium). In R.F. the bead is made dark red to violet (titanic acid). Fused with soda gives a green color (manganese). All varieties are decomposed by fusion with bisulphate of potash. Most specimens are sufficiently decomposed by muriatic acid to give a blue color when the concentrated solution is boiled with metallic tin; this color disappears after a time, and almost immediately if diluted with water.

Obs.—Occurs imbedded in syenite at Friederichsvärn and Laurvig, Norway, with zircon, polymignite, and xenotime; at Brevig, with thorite; and near Miask in the Urals.

Named from πῦρ, *fire*, and χλωρός, *green*, because B.B. it becomes yellowish-green.

472. MICROLITE. Microlite *C. U. Shepard*, Am. J. Sci., xxvii. 361, 1835, xxxii. 338, xliii. 116. Pyrochlore *Hayes*, ib., xliii. 33, xlvi. 158, 338.

Isometric. Forms octahedral. Observed planes: 1, *I*, 2-2 (or 3-3). Figs. 2, 8, 20+8. Known only in small crystals.

H.=5·5. G.=5·485–5·562, the last from a large crystal, Shepard; 5·405, Hayes. Lustre vitreous or resinous. Color pale clear yellow to brown. Streak pale yellowish or brownish. Translucent to opaque.

Comp.—The yellow crystals were made by Hayes essentially columbate of lime. From blowpipe investigation suggested by Brush to be probably (priv. contrib.) a pyrochlore, in which tantalic acid replaces the columbic, this corresponding with the high specific gravity and larger percentage of the metallic acid.

Analyses: 1, Shepard (l. c., xxxii. 338); 2 Hayes (ib., xlvi. 158):

	$\ddot{\mathrm{C}}\mathrm{b}(\dddot{\mathrm{T}}\mathrm{a}?)$	$\ddot{\mathrm{S}}\mathrm{n}$	$\bar{\mathrm{U}}, \bar{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{P}}\mathrm{b}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dddot{\mathrm{W}}, \dot{\mathrm{Y}}, \dot{\mathrm{U}}$	$\dot{\mathrm{H}}$
1. Chesterfield	75·70	——	——	——	14·84	7·42	2·04=100 Shepard.
2. "	79·60	0·70	2·21	1·60	10·87,	$\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·99=95·97 Hayes.	

Pyr., etc.—B.B. infusible. In salt of phosphorus difficultly soluble, giving in O.F. a bead yellow while hot, and colorless on cooling. In R.F. after long blowing yields a pale bluish-green bead. Not attacked by muriatic acid, but decomposed on fusion with bisulphate of potash, and the solution of the fused mass remains uncolored when boiled with metallic tin.

Obs.—Occurs at Chesterfield, Mass., in the albite vein, along with red and green tourmaline, columbite, and a little cassiterite.

Named from μικρός, *small*, alluding to the size of the crystals.

H.=6—6·5. G.=7—8. Lustre nearly pure metallic, somewhat adamantine. Color iron-black. Streak reddish-brown to black. Opaque. Brittle.

Comp., Var.—$(\dot{\mathrm{F}}\mathrm{e}, \dot{\mathrm{M}}\mathrm{n})\dddot{\mathrm{T}}\mathrm{a}$, with sometimes stannic acid ($\ddot{\mathrm{S}}\mathrm{n}$) replacing part of the tantalic. A tantalate either (1) of iron (anal. 1–11, 13–15, 19, 20), or (2) of iron and manganese (anal. 12), or (3) a stanno-tantalate of these two bases, part of the tantalic acid being replaced by oxyd of tin (anal. 16–18, 21–23). Number 1 is the *Ferrotantalite* of Thomson; 1 and 2, the *Siderotantalite* of Hausmann; 3, the *Cassiterotantalite* and *Ixiolite*. The kinds shade into one another. The last has the lowest specific gravity, G.=7—7·3. The mineral varies in the state of oxydation of the bases, owing, as Rose has shown, to alteration of the protoxyds to sesquioxyds; with the increase of the latter the streak loses its black color. It varies also in O. ratio for bases and acid between 1 : 4 and 1 : 5. The latter corresponds to Tantalic acid 86·05, protoxyd of iron 13·95, and the former to 83·1 and 16·9. Rose finds that prolonged washing of the powdered mineral carries off the iron.

Analyses: 1, Nordenskiöld (Jahresb., xii. 190); 2, Jacobson (Pogg., lxiii. 317); 3, Brooks (ib.), 4, Weber (Pogg., civ. 85); 5, 6, Arppe (Act. Soc. Sci. Fenn., vi.; Verh. Min. Tantalic and *columbic* acids were formerly supposed to contain either 3 or 2 of oxygen. and a *hypotantalic* and a *hypocolumbic* were recognized. The recent results of Marignac, confirmed by those of Blomstrand, have led to the conclusion that there is but one acid, and that this one contains 5 of oxygen, as represented in the symbol above used.

Klaproth obtained from the Kimito tantalite (Beitr., v. 5) $\ddot{\bar{\mathrm{Ta}}}$ 88, $\dot{\mathrm{Fe}}$ 10, $\dot{\mathrm{Mn}}$ 2=100; Vauquelin (Haüy Tabl., 308) $\ddot{\bar{\mathrm{Ta}}}$ 88, $\bar{\mathrm{Fe}}$ 12, $\dot{\mathrm{Mn}}$ 8=108; and Wollaston (Phil. Trans., 1809) $\ddot{\bar{\mathrm{Ta}}}$ 85, $\dot{\mathrm{Fe}}$ 10, $\dot{\mathrm{Mn}}$ 4=99.

Pyr., etc.—B.B. unaltered. With borax slowly dissolved, yielding an iron glass, which, at a certain point of saturation, gives, when treated in R.F. and subsequently flamed, a grayish-white bead; if completely saturated becomes of itself cloudy on cooling. With salt of phosphorus dissolves slowly, giving an iron glass, which in R.F., if free from tungstic acid, is pale yellow on cooling; treated with tin on charcoal it becomes green. If tungstic acid is present the bead is dark red, and is unchanged in color when treated with tin on charcoal. With soda and nitre gives a greenish-blue manganese reaction. On charcoal, with soda and sufficient borax to dissolve the oxyd of iron, gives in R.F. metallic tin. Decomposed on fusion with bisulphate of potash in the platinum spoon, and gives on treatment with dilute muriatic acid a yellow solution and a heavy white powder, which, on addition of metallic zinc, assumes a smalt-blue color; on dilution with water the blue color soon disappears (v. Kobell).

Obs.—Tantalite is confined mostly to albite or oligoclase granite, and is usually associated with beryl. Near Härkäsaari, tantalite is associated with rose quartz and gigantolite, in albitic granite. At Katiala it is associated with lepidolite, black tourmaline, and colorless beryl.

Occurs in Finland, in Tammela, at Härkäsaari near Torro, associated with gigantolite and rose quartz; in Kimito at Skogböle, in Somero at Kaidasuo, and in Kuortane at Katiala, with lepidolite, tourmaline, and beryl; in Sweden, in Fahlun, at Broddbo and Finbo; in France, at Chanteloube near Limoges, in pegmatite. *Ixiolite*, from Kimito, was instituted on a supposed (not real) difference of crystalline form. *Ildefonsite* is from Ildefonso, Spain, and has G.=7·416, H.=6–7.

Named *Tantalite* by Ekeberg, from the mythic Tantalus, in playful allusion to the difficulties (tantalizing) he encountered in his attempts to make a solution of the Finland mineral in acids. The name was afterward extended to the American mineral *columbite*, and to the same from other localities; while the name columbite, the metal columbium having been discovered a little prior to tantalum, received a similar extension, so as to include all tantalite. The subsequent discovery that tantalum and columbium were distinct metals, and that the two compounds differed also in the atomic proportions of the constituents, finally established them as independent species.

H.=6. G.=5·4—6·5. Lustre submetallic; a little shining. Color iron-black, brownish-black, grayish-black; often iridescent. Streak dark red to black. Opaque. Fracture subconchoidal, uneven. Brittle.

Comp., Var.—Columbate and tantalate of iron and manganese, of the general formula (Ḟe, Mn)(C̈b, T̈a), with at least twice as much atomically of columbic as of tantalic acid, and with the specific gravity increasing as the proportion of tantalic acid increases (Blomstrand, 1865; Marignac, 1866). The following are some of the ratios from Marignac's determinations: (1) From Greenland, T̈a 3·3 p. c.; C̈b : T̈a=35 : 1. (2) Acworth, N. H., La Vilate, near Limoges, and the *dianite* of Bodenmais, T̈a 15·8—13·4; C̈b : T̈a=7 or 8 : 1. (3) Another fr. Bodenmais, T̈a 27·1; C̈b : T̈a=3 : 1. (4) A third fr. Bodenmais, T̈a 35·4; C̈b : T̈a=about 2 : 1. (5) From Haddam, T̈a 30·4, and another 31·5; C̈b : T̈a=2·5 : 1. (6) In another from Haddam he found only 10 p. c. of tantalic acid, but queries the result. Blomstrand obtained for a Haddam specimen (anal

3) C̈b : T̈a=3 : 1, with G.=6·151; for one fr. Bodenmais (anal. 16), C̈b : T̈a=4 : 1, with G=5·75; another fr. B. (anal. 17), C̈b : T̈a=2·5 : 1, with G.=6·26; for one fr. Greenland, no T̈a with G.=5·395. His results all give for the O. ratio of bases and acids 1 : 5.

No. 3, above, gives the formula 3 (Ḟe, Ṁn) C̈b+(Ḟe, Ṁn) T̈a; and No. 4, 2 (Ḟe, Ṁn) C̈b+(Ḟe, Ṁn) T̈a; while 1 gives 35 (Ḟe, Ṁn) C̈b+(Ḟe, Ṁn) T̈a. Ḟe C̈b corresponds to columbic acid 78·83 protoxyd of iron 21·17=100.

The following are the G. of the specimens employed for the analyses below:

Connecticut, anal. 2, 5·469—5·495; 3, 5·708; 4, 5·8; 5, 5·58—5·59; 6, 6·028—6·048; 7, 5·85. *Bavaria*, anal. 9, 6·39; 11, 5·7; 12, 6·02 -6·06; 13, 5·976; 14, 5·971; 15, 5·698. *Ilmen Mts.*, anal. 19, 5·49—5·73; 20, 5·461; 21, 5·447. *Greenland*, anal. 22, 23, 5·375; 24, 5·40—5·42. *Chanteloube*, anal. 27, 5·60—5·727. Other G. are as follows:

C. fr. Northfield, Mass., 6·5, Shepard; fr. Monte Video, S. A., 5·660, Maskelyne; fr. Haddam, 5·967 Schrauf; fr. Middletown, 5·590 and 5·645, id.; fr. Greenland, 5·395, id.; fr. Bodenmais, 6·115, id.

The Bodenmais specimens, having the highest G., give a black powder; and others, of less, dark reddish-brown, but as a result of partial alteration, Rose.

The angles of the crystals vary considerably. The angles above given are those calculated by Schrauf after a study of the crystals of various localities, adopting for the basis *i*-ī ∧ 1-ĭ=104° 30′ (obs. on Greenland crystals), and *i*-ī ∧ *i*-ĭ=112° 10′ (112° 20′, obs. on Gr. cryst.). The author obtained somewhat different results from a Middletown crystal, f. 429 (this Min., edit. of 1837, et seq., Am. J. Sci., xxxii. 150, 1837): *i*-ī ∧ 1-ĭ=104° 52′; *i*-ī ∧ *I*=140° 40′, whence *I* ∧ *I*=100° 40′; *i*-ī ∧ *i*-ĭ=158° 6′, whence *i*-ī ∧ *i*-ĭ=111° 54′; *O* ∧ ½-ī=160° 34′, whence *i*-ī ∧ ½-ī=109° 26′; *O* ∧ 1-ĭ=136° 36′; *O* ∧ 2-ĭ=119° 40′; 1-ĭ ∧ 1-ĭ, adj.,=150° 17′. The angles *I* ∧ *I*=100° 40′, *O* ∧ ½-*i*=160° 34′, correspond to the dimensions *a* : *b* : *c*=1·0584 : 1 : 1·2059. Schrauf's measurements gave him for *i*-ī ∧ *I*=140° 30′. fr. Greenland and Bodenmais; *i*-ī ∧ ½-ī=108°, fr. B.

The crystals from Bavaria, Miask, Connecticut, Chesterfield, Mass., and Monte Video, have the general form shown in f. 429, 430, though sometimes with the basal plane wanting; while those of Greenland have the habit generally of f. 431 (fr. Schrauf's paper). Occasionally the octahedral planes are very much elongated, producing crystals with long pyramidal summits, as a kind from Acworth, N. H. (Shep., Am. J. Sci., xvii. 358, 1830).

* Ilmenic acid of Hermann.

Wollaston's analysis was made on four grains of the original specimen in the British Museum, sent out from Connecticut by Governor Winthrop to Sir Hans Sloane.

Pyr., etc.—Like tantalite. Von Kobell states that when decomposed by fusion with caustic potash, and treated with muriatic and sulphuric acids, it gives, on the addition of zinc, a blue color much more lasting than with tantalite; and the variety dianite, when similarly treated, gives on boiling with tin-foil, and dilution with its volume of water, a sapphire-blue fluid, while, with tantalite and ordinary columbite, the metallic acid remains undissolved. The variety from Haddam, Ct., is partially decomposed when the powdered mineral is evaporated to dryness with concontrated sulphuric acid, its color is changed to white, light gray, or yellow, and when boiled with muriatic acid and metallic zinc it gives a beautiful blue. The remarkably pure and unaltered columbite from Arksut-fiord in Greenland is also partially decomposed by sulphuric acid, and the product gives the reaction test with zinc, as above.

Obs.—Occurs at Rabenstein, Bavaria, near Zwiesel, not far from Bodenmais, in granite, with iolite and magnetite; at Tirschenreuth, Bavaria; at Tammela, in Finland; at Chanteloube, near Limoges, in pegmatite with tantalite; near Miask, in the Ilmen Mts., with samarskite; at Hermanskär, near Björskär, in Finland; in Greenland, in cryolite, at Evigtok, in brilliant crystals disseminated through or among the wolfram of Auvergne, and detected by acting with aqua-regia which dissolves the wolfram and leaves untouched the columbite (Phipson, Chem. News, 1867, 160); at Monte Video, S. A.

In the United States, at Haddam, 2 m. from the village, in a granite vein, some of the crystals several pounds in weight; also at the chrysoberyl locality, but not now accessible; also at the iolite locality, Haddam; near Middletown, in the "feldspar" or "china-stone quarry," with albite, abundant in fine crystals some very large; figure 429 represents one ¾ in. long; another, described by Professor Johnston (Am. J. Sci., xxx. 387), weighed, before it was broken, 14 pounds; and the part figured about 6 in. in length and breadth, weighed 6 lbs. 12 oz.; it exhibits the faces *i*-ī, *i*-ĭ, *i*-2̆, *I*, *i*-3̆, ½-ī, and another imperfect plane, which appears to be 1-3̆. At Chesterfield, Mass., some fine crystals, associated with blue and green tourmalines and beryl, in a vein of albitic granite; Acworth, N. H.; also Beverly, Mass.; Northfield, Mass., with beryl; Plymouth, N. H., with beryl; Greenfield, N. Y., with chrysoberyl.

The Connecticut crystals are usually rather fragile from partial change; while those of Greenland are very firm and hard.

The occurrence of columbite in America was first made known by Mr. Hatchett's examination of a specimen sent by Governor Winthrop to Sir Hans Sloane, then President of the Royal Society, which was labelled as found at Neatneague. Dr. S. L. Mitchill stated (Med. Repos., vol. viii.) that it was taken at a spring at New London, Conn. No locality has since been detected at that place. But the rediscovery of it at Haddam, first published by Dr. Torrey (Am. J. Sci., iv. 52), and since near Middletown, about 7 m. distant, has led to the belief that the original locality was at one of these places, which are about 30 m. W. of New London.

For recent papers on cryst. see Descl., Ann. d. M., V. viii. 395; Schrauf, Ber. Ak. Wien, xliv. 445, 1861; Maskelyne, Phil. Mag., IV. xxv. 41. The crystallographic identity of the American mineral with the Bavarian was first shown by Dr. J. Torrey (Ann. Lyc. N. Y., i. 89, 1824).

The metal of columbite was named columbium by Hatchett in 1802, from Columbia, a name of America, whence his specimen was received, and thus came the name *columbite* given by Jameson and Thomson (see further under tantalite). Rose, after investigating the metal and its compounds, named it anew, calling it *niobium*, and this gave rise to the name *niobite*. *Baierite* is from the German name of Bavaria. *Torrelite* Thomson, named after Dr. J. Torrey, is the ordinary Middletown columbite: and *Greenlandite* Breith., is that from Greenland; both names originated partly in erroneous views of the crystals of the minerals. *Dianite* is the Bodenmais columbite, in which v Kobell supposed he had discovered the acid of a new metal, which he called *dianium*.

No good reason has been given for substituting *niobium* for *columbium*; and yet most English chemists, as well as European, have thus far followed Rose in rejecting the name given by the English discoverer. The rule of priority demands recognition.

476. TAPIOLITE. Tapiolit *A. E. Nordenskiöld*, Œfv. Ak. Stockh., 443, 1863. Tantalite (fr. Sukula) *Arppe*, Act. Soc. Sci. Fenn., vi. 590, 1861.

Tetragonal. $O \wedge 1\text{-}i=147^\circ\ 7'$; $a=0{\cdot}6464$. $1 \wedge 1$ in same pyramid 123° 1′, over base 84° 52′; $O \wedge 1=137^\circ\ 34'$; $1 \wedge 1\text{-}i=151^\circ\ 30'$. Cleavage indistinct.

H.=6. G.=7·35–7·37, Nord.; 7·17–7·36, Arppe. Lustre strong adamantine, approaching metallic. Color pure black.

Comp.—$\dot{\mathrm{F}}\mathrm{e}^5\,\overset{\cdots}{\mathrm{T}}\mathrm{a}^4$=Tantalic acid 83·1, protoxyd of iron 16·9=100. **Analyses**: 1, Arppe (l. c.) 2, Nordenskiöld (l. c.):

		$\overset{\cdots}{\mathrm{T}}\mathrm{a}$	$\ddot{\mathrm{S}}\mathrm{n}$	$\dot{\mathrm{F}}\mathrm{e}$
1.	Sukula	(⅞) 83·18	0·82	15·77=99·77 Arppe.
2.	"	(⅞) 83·06	1·07	15·78=99·91 Nordenskiöld. *Tr.* of $\dddot{\mathrm{W}}$ with $\ddot{\mathrm{S}}\mathrm{n}$.

Pyr., etc.—B.B. behaves like tantalite, but gives no reaction for manganese.

Obs.—Occurs near the Kulmala farm, in the village of Sukula, in the parish of Tammela, Finland, in white pegmatyte granite, with beryl, tourmaline, and arsenopyrite.

Named from an ancient Finnish divinity.

476. HIELMITE. Hjelmit *A. E. Nordenskiöld*, Pogg., cxi. 286, 1860.

Crystallization indistinct. Massive, without apparent cleavage.

H.=5. G.=5·82. Lustre metallic. Color pure black. Streak grayish-black. Fracture granular.

Comp.—A stanno-tantalate of iron, uranium, and yttria. **Analysis**: Nordenskiöld (l. c.):

$\overset{\cdots}{\mathrm{T}}\mathrm{a}$	$\ddot{\mathrm{S}}\mathrm{n}$, $\dddot{\mathrm{W}}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{U}}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{C}}\mathrm{e}$	$\dot{\mathrm{Y}}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$
62·42	6·56	0·10	4·87	8·06	3·32	1·07	5·19	0·26	4·26	3·26=99·37.

Pyr., etc.—In the closed tube decrepitates and yields water. B.B. infusible, but turns brown in O.F. With salt of phosphorus easily dissolved to a bluish-green glass. With borax dissolves to a clear glass, which remains unchanged on flaming. With soda on charcoal gives metallic spangles (Nordenskiöld).

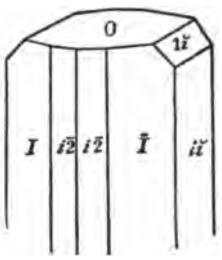
Obs.—From the Kararfvet mine, near Fahlun, Swedon, along with garnet, pyrophysalite, gadolinite, asphaltum, in a pegmatyte granite.

477. YTTROTANTALITE. Yttrotantal *Ekeberg*, Ak. H. Stockh., xxiii. 80, 1802. Tantale oxidé yttrifère *H.*, Tr., 1822. Yttroilmenit *Herm.*, J. pr. Ch., xxxviii. 119, 1846.

Orthorhombic. $I \wedge I=123^\circ\ 10'$; $O \wedge 2\text{-}\bar{i}=103^\circ\ 26'$; $a:b:c=2{\cdot}0934:1:1{\cdot}8482$. Observed planes: O; vertical, $i\text{-}\breve{i}$, I, $i\text{-}\breve{2}$, $i\text{-}\bar{2}$, $i\text{-}\breve{5}$; domes, $1\text{-}\breve{i}$, $2\text{-}\bar{i}$. $O \wedge 1\text{-}\breve{i}=131^\circ\ 26'$, $i\text{-}\breve{i} \wedge 1\text{-}\breve{i}=138^\circ\ 34'$, $i\text{-}\breve{i} \wedge I=118^\circ\ 25'$, $i\text{-}\breve{i} \wedge i\text{-}\bar{2}=137^\circ\ 16'$, $i\text{-}\breve{i} \wedge i\text{-}\breve{2}=105^\circ\ 9'$, $i\text{-}\breve{2} \wedge i\text{-}\breve{2}$, ov. $i\text{-}\breve{i}$,$=94^\circ\ 32'$, $i\text{-}\breve{2} \wedge i\text{-}\breve{2}$, adj.,$=149^\circ\ 42'$, $i\text{-}\breve{i} \wedge i\text{-}\breve{5}=159^\circ\ 43'$. Crystals often tabular parallel to $i\text{-}\breve{i}$. Also massive; amorphous.

H.=5–5·5. G.=5·4–5·9. Lustre submetallic to vitreous and greasy. Color black, brown, brownish-yellow, straw-yellow. Streak gray to colorless. Opaque to subtranslucent. Fracture small conchoidal to granular.

432



Ytterby.

Var.—1. The *black* yttrotantalite, of Ytterby, is iron-black, submetallic in lustre, and has G.=5·395, Berz.; 5·67, Peretz; after ignition 6·40, Peretz; 7·09, Nordenskiöld. Often in crystals.

2. The *yellow* of Ytterby is amorphous or indistinctly crystallized, and has G.=5·882, Ekeberg, 5·458, Chandler; after ignition, 6·40, Peretz; 5·845, Chandler. 3. The *yellow* from Kararfve has G.=5·640, Chydenius. This variety contains much uranium.

Hermann calls the mineral of anal. 5, 6, 7, *yttrotantalite*, and that of his own analysis *yttroilmenite*, giving G.=4·88.

Comp.—Tantalate of yttria and lime, or yttria, lime, and iron, with some protoxyd of uranium; $(\dot{\text{Y}}, \dot{\text{Fe}}, \dot{\text{Ca}}, \dot{\text{U}})^{10} \dddot{\text{Ta}}^{3}$=, if $\dot{\text{Y}} : \dot{\text{Ca}} : \dot{\text{Fe}} : \dot{\text{U}}=6 : 2 : 1 : 1$, Tantalic acid 62·5, yttria 22·6, lime 5·2, protoxyd of iron 3·4, prot. uranium 6·3=100. Analyses: 1–4, Berzelius (Afhandl., iv. 268, 272, Schw. J., xvi. 451); 5, Peretz (Pogg., lxxii. 155); 5A, same, with 4·86 $\dot{\text{H}}$, the mean loss by ignition (Ramm. Min. Ch., 400); 6, Chandler (Inaug. Dissert.); 7, Potyka (Inaug. Dissert.); 8 Nordenskiöld (Pogg., cxi. 280); 9, J. J. Chydenius (ib., 284); 10–12, Hermann (Bull. Soc. Nat Mosc., xxxviii. 358):

[a] Hermann's ilmenic acid. [b] Niobous acid of Hermann.

Blomstrand has found 16 p. c. of columbic acid in the yellow yttrotantalite; he regards Hermann's ilmenic acid as having no existence. Marignac confirms this statement, and has shown ilmenic acid (G. 3·8) to be columbic acid mixed with titanic acid, while his "niobic" acid (G.=5) contained tantalic acid. In anal. 1, 2, 4·64 p. c. of $\dot{\text{H}}$ were found, and in 3, 5·43.

Pyr., etc.—In the closed tube yields water, the black varieties turn yellow. On intense ignition both varieties become white and give off traces of fluorine. B.B. infusible. With salt of phosphorus dissolves with at first a separation of a white skeleton of tantalic acid, which with a strong heat is also dissolved; the black variety from Ytterby gives a glass faintly tinted rose-red from the presence of tungstic acid; the dark and yellow varieties give a faint green bead on cooling, due to the presence of uranium. The mineral from Finbo and Kararfvet gives an iron glass. With soda reacts for manganese. With soda and borax on charcoal gives traces of metallic tin (Berzelius). Not decomposed by acids. Decomposed on fusion with bisulphate of potash, and when the product is boiled with muriatic acid metallic zinc gives a pale blue color to the solution which soon fades.

Obs.—Occurs in Sweden at Ytterby, near Vaxholm, in red feldspar; at the Kararfvet mine, and at Finbo and Broddbo, near Fahlun, imbedded in quartz and albite, associated with garnet, mica, and pyrophysalite.

On cryst. see A. E. Nordenskiöld, Œfv. Ak. Stockh., 1860, 28, cited in Pogg., cxi. 280, and J. pr. Ch., lxxxi. 193.

The name *yttrotantalite* alludes to the composition. *Yttroilmenite* was given to a variety by Hermann upon the discovery in it of his *supposed* new metal ilmenium.

478. SAMARSKITE. Uranotantal *H. Rose*, Pogg., xlviii. 555, 1839. Samarskit *H. Rose* Pogg., lxxi. 157, 1847. Uranoniobit *H. Rose*, Pogg., lxxi. 166, 1847. Yttroilmenit *Herm.*, xlii. 129, 1847, J. pr. Ch., xliv. 216, 1848.

Orthorhombic. Angle of prism i-$\breve{2}$, 135° to 136° (whence $I \wedge I$=100° 40′ to 101° 40′, near that of columbite). Usually in flattened grains.

H.=5·5–6. G.=5·614–5·75; 5·45–5·69, North Carolina. Lustre of surface of fracture shining and submetallic. Color velvet-black. Streak dark reddish-brown. Opaque. Fracture subconchoidal.

Comp.—Analyses: 1, 2, 3, Peretz, under the direction of Rose (Pogg., lxxi. 157); 4, Chandler (Inaug. Dissert.); 5, Hermann (J. pr. Ch., l. 178); 6, T. S. Hunt (Am. J. Sci., II. xiv. 341):

5.	"	56·36		Ü16·63	8·87	13·29	0·50,	Ċe, L̇a 2·85, Ṁn 1·20, ign. 0·33=100·03 H.
6.	N. Carolina	54·81		" 17·08	14·07	11·11,		Ċe, L̇a 3·95, ign. 0·24=101·21 Hunt.

Later Finkener and Stephans have obtained from the Miask mineral (H. Rose in Verh. Min St. Pet., 1863, 13):

C̈b	Ẅ	Ü	Z̈r	S̈n	T̈h	Ḟe	Ṁn	Ċu	Ċe	Ẏ	Ṁg	Ċa	Ḣ
47·47	1·36	11·60	4·35	0·5	6·05	11·02	0·96	0·25	3·31	12·61	0·14	0·73	0·45=100·55
50·17		11·08	4·25	0·63	5·55	10·55	1·60	—	15·90		0·04	0·64	0·40=100·82

Giving for the O. ratio between the C̈b [+Ẅ] and the other ingredients 9·49 : 9·65=1 : 1, whence the general formula $(\dot{R}^3, \dot{H}, \ddot{R}^{\frac{3}{2}})^3\ \ddot{C}b^2$.

Pyr., etc.—In the closed tube decrepitates, glows like gadolinite, cracks open, and turns black, and is of diminished density. B.B. fuses on the edges to a black glass. With borax in O.F. gives a yellowish-green to red bead, in R.F. a yellow to greenish-black, which on flaming becomes opaque and yellowish-brown. With salt of phosphorus in both flames an emerald-green bead. With soda yields a manganese reaction. Decomposed on fusion with bisulphate of potash, yielding a yellow mass which on treatment with dilute muriatic acid separates white tantalic acid, and on boiling with metallic zinc gives a fine blue color. Samarskite in powder is also sufficiently decomposed on boiling with concentrated sulphuric acid to give the blue reduction test when the acid fluid is treated with metallic zinc or tin.

Obs.—Uranotantalite occurs in reddish-brown feldspar, with crystallized æschynite, in the Ilmen mountains, near Miask in the Ural. The largest pieces met with were of the size of hazel-nuts.

If the occurring prism of Samarskite is *i-3̆* instead of *i-2* (as in mengite), then *I* ∧ *I* becomes 100° 57′ to 102° 20′.

Named after the Russian, v. Samarski.

479. EUXENITE. Euxenit *Scheerer*, Pogg., l. 149, 1840, lxxii. 566.

Orthorhombic. Form a rectangular prism (*i-ī*, *i-ĭ*) with lateral edges replaced by *I*, and a pyramid at summit, also with a macrodome *m-ī*. *I* ∧ *I*=126°, *i-ī* ∧ *m-ī*=154° 30′, *i-ĭ* ∧ pyramid=107°, Dahl; *I* ∧ *I*=120°?, *i-ī* ∧ *m-ī*=153°, *i-ĭ* ∧ *m-ĭ*=124°, *i-ī* ∧ pyr.=136°, Greg; prism of 141°, macrodome of 59° 15′, Breith. Cleavage none. Commonly massive.

H.=6·5. G.=4·60, Jölster, Scheerer; 4·73—4·76, Tvedenstrand, id.; 4·94—4·99, ib., Breith.; 4·89—4·99, Alve, Forbes; 4·96, Chydenius. Lustre brilliant, metallic-vitreous, or somewhat greasy. Color brownish-black; in thin splinters a reddish-brown translucence lighter than the streak. Streak-powder yellowish to reddish-brown. Fracture subconchoidal.

Comp.—A columbo-tantalate, containing titanic acid, yttrium, and uranium. O. ratio for Ṙ, T̈i, C̈b+T̈a= (from mean of anal. 3, 4) 8 : 6 : 7; and if the titanic is basic, the ratio for the bases and C̈b+T̈a is 2 : 1, which would give the formula $(\dot{R}^3, \ddot{T}i)^3(\ddot{C}b, \ddot{T}a)$. If T̈i is acid, the ratio is 8 : 13. Hermann makes it isomorphous and similar in formula with æschynite. Analyses: 1, 2, Scheerer (l. c.); 3, Forbes & Dahl (Ed. N. Phil. J., II. i. 62); 4, Strecker (J. pr. Ch., lxiv. 384); 5, Chydenius (Bull. Soc. Ch., vi. 434, 1866):

		C̈b, T̈a	T̈i	Äl	Ü	Ḟe	Ċe	L̇a	Ẏ	Ṁg	Ċa	Ḣ
1.	Jölster	49·66	7·94	—	6·34	—	2·18	0·96	25·09	0·29	2·47	3·97 Scheerer.
2.	Tvedenstrand	53·64		—	7·58	2·60	2·91		28·97	—	—	4·04=99·74 Scheerer.
3.	Alve	38·58	14·36	3·12	5·22	1·98	3·31	—	29·36	0·19	1·37	2·88=100·37 F. & D.
4.	Tromoen	37·16	16·26	—	8·45	3·03	26·46			—	5·25	2·68=100·89 Strecker.
5.	Arendal	54·28		—	—	—	T̈h 6·28		34·58	—	—	2·60=97·74 Chydenius

The Jölster euxenite contains the most titanic acid; yet Scheerer does not doubt the identity of the two minerals.

Chydenius has shown that the mineral contains thoria, and only traces of oxyd of cerium. Marignac (Bib. Univ., xxv. 29, 1866) found 52·28 of metallic acid, consisting of about 32·5 p. c. of C̆b and 29·7 of titanic, the ratio of the two being stated at 268 : 243.

Pyr., etc.—B.B. infusible. Dissolves in borax and salt of phosphorus, giving a yellow bead while hot; with salt of phosphorus shows a yellowish-green (uranium reaction) on cooling, if sufficiently saturated (Scheerer). When decomposed by fusion with caustic potash, and subsequently treated with water, and this solution neutralized with muriatic acid, it gives a precipitate, which, boiled with concentrated muriatic acid and tin-foil, gives a clear sapphire-blue fluid, which changes to an olive-green, and finally bleaches. If the residue of the fusion after leaching is treated with muriatic acid and boiled with tin-foil, it yields on dilution a pale rose-red color (v. Kobell). The mineral is sufficiently attacked, on evaporation with sulphuric acid, to give a whitish residue, which, treated with metallic zinc or tin, affords the characteristic blue reduction test.

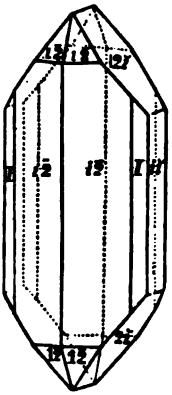
Obs.—Occurs at Jölster in Norway, imbedded in feldspar and sometimes in scaly mica, the largest crystals 2 in. long and ¼ in. wide, but usually much smaller; also near Tvedenstrand; at Alve, island of Tromoen, near Arendal; at Mõretjär, near Naskilen.

Named by Scheerer from εὔξενος, *a stranger*, in allusion to the rarity of its occurrence.

480. ÆSCHYNITE. Æschynit *Berz.*, Jahresb., ix. 195, 1828.

Orthorhombic. *I* ∧ *I*=91° 34½′, *O* ∧ 1-ĭ=145° 18′, Kokscharof; *a* : *b* : *c* =0·69244 : 1 : 1·0279. Observed planes: *O* (not common); vertical, i-2̆, *I*, i-ĭ; brachydome, 2-ĭ; octahedral, 1-2. Crystals usually long prismatic and striated. Cleavage: i-ĭ in traces, or none; none observable according to Kokscharof.

433



i-2̆ ∧ i-2̆=128° 6′
i-2̆ ∧ i-ĭ=115 57
I ∧ i-ĭ=134 13½
2-ĭ ∧ 2-ĭ, top,=73 10
2-ĭ ∧ i-ĭ=143° 25′
1-2̆ ∧ 1-2̆, adj.,=136 56½
i-2̆ ∧ 1-2̆=146 60
2-ĭ ∧ 1-2̆=128 16

H.=5–6. G.=4·9–5·14; 5·118, Miask, Kokscharof. Lustre submetallic—resinous, nearly dull. Color nearly black, inclining to brownish-yellow when translucent. Streak gray, or yellowish-brown, almost black. Subtranslucent—opaque. Fracture small subconchoidal.

Comp.—Doubtful. The mineral described by Berzelius and analyzed by Hartwall differs much in the pyrognostic and other characters given from that from the same locality investigated by Hermann, and the identity of the two is not yet certain. Scheerer found no zirconia. Analyses: 1, Hartwall (Pogg., xvii. 483, Jahresb., ix. 195); 2–4, Hermann (J. pr. Ch., xxxi. 89, xxxvii. 116, l. 170, lxviii. 97); 5, id. (Bull. Soc. Nat. Moscou, xxxviii. 472, J. pr. Ch., xcix. 288); 6, id. (Bull. Soc. Nat. Moscou, xxxix. 55, 1866):

[a] Made 29·00 ilmenic acid (or, later, 12·28 ilmenic, and 16·72 ilmenous acid) plus 3·30 niobous acid.

[b] Made 30·16 ilmenic acid plus 3·43 niobous acid.

[c] Ce O, La O, Di O.

Hermann's analyses afford for the O. ratio of bases, T̈i, C̆b+T̈a 7·9 : 6·0 : 8·2, as deduced by him, or 13·9 : 8·2 for bases+T̈i, and C̆b+T̈a. His ilmenic acid is made tantalic and columbic.

Pyr., etc.—In the open tube yields water and traces of fluorine. B.B. in the forceps swells up and changes its color from black to a rusty brown. In borax dissolves easily in O.F., giving a yellow bead while hot, and on cooling becomes colorless; in R.F. with tin gives a blood-red bead. More difficultly soluble in salt of phosphorus; with a small amount of the assay gives a colorless bead, while with a larger quantity there separates a white substance which clouds the bead; in R.F., with tin on charcoal, yields an amethystine glass (Berzelius). Decomposed on fusion with potash; yields reactions similar to those mentioned under euxenite (v. Kobell). It is also sufficiently decomposed by sulphuric acid to show the reduction test with zinc.

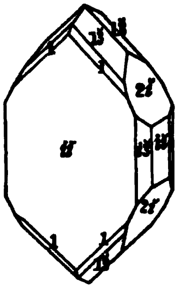
Obs.—From Miask in the Ilmen Mts., in feldspar with mica and zircon; also with euclase in the gold sands of "Kaufmann's Bakakin," in the Orenburg District, Southern Ural.

Named from αἰσχυνή, *shame*, by Berzelius, in allusion to the inability of chemical science, at the time of its discovery, to separate the two unlike substances, titanic acid and zirconia.

On cryst. see Brooke, Phil. Mag., x. 188; Rose, Reis. Ural., ii. 70; Descloizeaux, Ann. d. M. IV ii. 349; Kokscharof, Min. Russl., iii. 384, iv. 53, 100. Rose made *i*-2̆ ∧ *i*-2̆=127° 19′, and 2-ĭ ∧ 2-ĭ=73° 44′, which he says are approximations only, the faces being rough. Fig. 483 is by Rose.

481. POLYCRASE. Polykras *Scheerer*, Pogg., lxii. 480, 1844.

434



Orthorhombic. *I* ∧ *I*=95°, *O* ∧ 1-ī=134° 15′; *a* : *b* : *c*=1·02655 : 1 : 1·0913. Observed planes as in the figure.

O ∧ 2-ĭ=118° 0′
O ∧ 1=125 41½
O ∧ 1-3̆=139 59
1-3̆ ∧ 1-3̆, mac.,=96 40

i-3̆ ∧ *i*-3̆, ov. *i*-ĭ,=140
i-ĭ ∧ *i*-3̆=160
2-ĭ ∧ *i*-ĭ=152

Crystals thin linear. Cleavage none.

H.=5·5. G.=5·09—5·12. Lustre bright. Color black; in splinters brownish. Streak grayish-brown. Fracture conchoidal.

Comp.—According to Scheerer, contains columbic acid, oxyd of uranium, titanic acid, zirconia, oxyd of iron, yttria, and protoxyd of cerium, with a little alumina, and traces of lime and magnesia.

Pyr., etc.—In the closed tube decrepitates, and gives traces of water. B.B. in the forceps glows, and turns to a light grayish-brown color, but is infusible. Soluble in borax, giving in O.F. a clear yellow bead, which in R.F. with tin turns brown. In salt of phosphorus gives a clear yellow glass, which on cooling is greenish; in R.F. the color becomes darker. With soda no reaction for manganese, and on charcoal no metallic particles. Decomposed by evaporation with concentrated sulphuric acid; the product, treated with muriatic acid, gives on boiling with metallic zinc or tin a deep azure-blue solution, which does not fade. The dilute solution gives a deep orange to turmeric paper (zirconia).

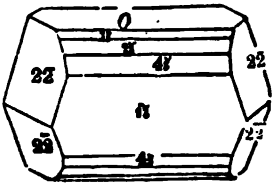
Obs.—From Hitteröe, Norway, in granite with gadolinite and orthite; crystals ½ to 1½ in. long; also near Dresden.

Named from πολύς, *many*, and κράσις, *mixture*.

N. B. Moller makes the so-called polycrase of Brevig certainly, and that of Hitteröe probably, identical with polymignite (J. pr. Ch., lxix. 318). Scheerer mentions a prism of 93° 32′ (B. H. Ztg., xvii. 22), and Breithaupt one of 59° and 121°.

482. POLYMIGNITE. *Berzelius*, Ak. H. Stockh., 338, 1824.

435



Orthorhombic. *I* ∧ *I*=91° 44′, *O* ∧ 1-ī=144° 3′; *a* : *b* : *c*=0·7252 : 1 : 1·0308. Observed planes: *O*; 1-ĭ, 2-ĭ, 4-ĭ, *i*-ĭ; 2-2̆.

O ∧ 1-ĭ=144° 53′
O ∧ 2-ĭ=125 15
O ∧ 2-2̆=121 49
i-ĭ ∧ 4-ĭ=160 26
i-ĭ ∧ 2-2̆=111 46

2-2̆ ∧ 2-2̆, mac.,=136° 28′
2-2̆ ∧ 2-2̆, brach.,=99 14
2-2̆ ∧ 2-2̆, bas.,=116 22
1-ĭ ∧ 1-ĭ, ov. *O*,=109 46
i-ĭ ∧ 1-ĭ=125 7

Cleavage: *i-i* and *O* in traces. Crystals generally slender and thin, and striated longitudinally.

H.=6·5. G.=4·77—4·85. Lustre submetallic but brilliant. Color black. Streak dark brown. Opaque. Fracture perfect conchoidal, presenting, like the surface, a brilliancy almost metallic.

Comp.—According to an analysis by Berzelius (Ak. H. Stockh., ii. 389, 1824), imperfect because of the difficult separation of the titanic acid and zirconia:

$$\ddot{\mathrm{Ti}}\ 46{\cdot}30\quad \ddot{\mathrm{Zr}}\ 14{\cdot}14\quad \mathrm{\bar{F}e}\ 12{\cdot}20\quad \dot{\mathrm{C}}\mathrm{a}\ 4{\cdot}20\quad \mathrm{\bar{M}n}\ 2{\cdot}70\quad \mathrm{\bar{C}e}\ 5{\cdot}00\quad \dot{\mathrm{Y}}\ 11{\cdot}50=96{\cdot}04,$$

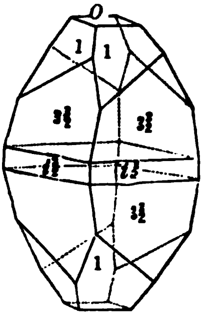
with a trace of potash, magnesia, silica, and oxyd of tin. The blowpipe reactions indicate the probable presence also of *columbic* or *tantalic acid* as an essential constituent (Brush).

Pyr., etc.—B.B. infusible, and unchanged in color. With borax dissolves readily, giving an iron bead; with more of the assay becomes brownish-yellow on flaming, and opaque on cooling; with tin in R.F. turns reddish-yellow. With salt of phosphorus not easily acted upon, gives a reddish tinge in R.F., which is unchanged by tin. With soda shows traces of manganese (Berzelius). The powdered Fredericksvärn mineral, heated with concentrated sulphuric acid, gives a whitish residue, which, treated with muriatic acid and tin-foil gives a beautiful azure-blue color, indicating, as under polycrase, the presence of some other metallic acid in addition to titanic, which of itself gives only a violet color. The dilute acid solution gives with turmeric paper the orange color characteristic of zirconia.

Obs.—Occurs at Fredericksvärn in Norway, imbedded in feldspar and zircon-syenite. Its crystals sometimes exceed an inch in length. Reported by Shepard as occurring at Beverly, Mass.

483. FERGUSONITE. *Haidinger*, Ed. Phil. Trans., x. 274, 1826.

436.



Tetragonal, hemihedral. $O \wedge 1\text{-}i=124°\ 20$; $a=1{\cdot}464$. Observed planes as in the annexed figure. $O \wedge 1=115°\ 46'$, $1 \wedge 1=100°\ 54'$, and $128°\ 28'$, $3\text{-}\frac{3}{2} \wedge 3\text{-}\frac{3}{2}=91°\ 59'$, $i\text{-}\frac{3}{2} \wedge 3\text{-}\frac{3}{2}=169°\ 17'$. Cleavage: 1, in distinct traces.

H.=5·5—6. G.=5·838, Allan; 5·800, Turner. Lustre externally dull, on the fracture brilliantly vitreous and submetallic. Color brownish-black; in thin scales pale liver-brown. Streak pale brown. Subtranslucent—opaque. Fracture imperfect conchoidal.

Comp., Var.—Varies much in composition, according to the analyses, like other columbium minerals, and probably as a result of alteration. The description above given is from (1) the *Greenland* fergusonite

2. A *mineral from Ytterby*, according to Nordenskiöld, is very similar in its hemihedral crystallization and form, but contains 6 p. c. of water (anal. 3, 4); as pyrochlore is sometimes hydrous, this peculiarity may be one of the effects of alteration. It has an imperfect basal cleavage; a vitreous to greasy lustre; a dark brown color; H.=4·5; G.=4·89; and is feebly subtranslucent.

3. *Tyrite* Forbes (Ed. N. Phil. J., i. 67, 1855, and Phil. Mag., IV. xiii. 91) occurs in square pyramidal crystals like those of fergusonite, and sometimes 2 inches long, with occasionally, according to Kenngott, planes corresponding to *O*, 1, 3, $\frac{1}{2}$, and hemihedral; but with the faces too uneven for exact measurement. It has one cleavage distinct, and traces of two others; color brownish-black; H.=6·5; G.=5·13—5·56, Forbes; 5·555, Kenngott. It contains water, but approaches fergusonite in composition (anal. 5, 6). It is from Hampemyr and Helle, near Arendal, Norway, and the crystals often stand on plates of black mica.

4. A mineral from the Norwegian locality of tyrite, and supposed to be that species (the specimen having been sent as such from Krantz to H. Rose), has been analyzed with still different results by J. Potyka (Pogg., cvii. 590), he finding in it 7 p. c. of potash (anal. 7). It was an irregular mass imbedded in reddish feldspar, had no cleavage, a submetallic lustre, a black color, reddish-brown at the edges in thin splinters, a reddish-brown streak, and H.=4, G.=5·124.

This last mineral, the tyrite, the Ytterby mineral, and fergusonite, may be four distinct species, but it does not appear probable.

5. *Bragite* of Forbes and Dahl, from Helle, Narostö, Alve, and Askerö, Norway, has been referred to fergusonite by J. A. Michaelson (J. pr. Ch., xc. 108). F. & D. describe the mineral as tetragonal, with H.=6–6·5; G.=5·13–5·36; color brown; streak yellowish-brown; lustre submetallic; thin splinters translucent; and as losing water when heated; but infusible B.B., and becoming yellow; and as affording, with salt of phosphorus, a skeleton of silica; characters which suggest a relation to hydrous or altered zircon, where it is placed on p. 276. Michaelson's mineral is grayish-brown, has H.=4·5, G.=5·40, and contains no silica (anal. 8).

Analyses: 1, Hartwall (Ak. H. Stockh, 167, 1828); 2, Weber (Pogg., cvii. 190); 3, Nordenskiöld (J. pr. Ch., lxxxi. 200); 4, Berzelius (Afh. i. Fys., etc., iv. 281). *Tyrite:* 5, 6, D. Forbes (l. c.); 7, Potyka (Pogg., cvii. 590); 8, Michaelson (l. c.):

8. Helle, *Bragite?*	48·10	—	—	1·45	—	32·71	$\ddot{C}$ 7·43	—	4·95	1·37	1·82	1·03	, $\dot{M}n$ 0·11, $\dot{M}g$ 0·39, $\dot{P}b$ 0·09, Mich.

Weber's analysis gives for the O. ratio of protoxyds, zirconia and tin-oxyd, and columbic acid, 4·5 : 1 : 5; and, if the zirconia is basic, for bases and acid nearly 1 : 1=$(\ddot{R}^2, \dot{R})^3 \ddot{C}b^2$. The Ytterby mineral also affords very closely the ratio 1 : 1; tyrite about 9 : 11; Potyka's mineral 9 : 9½, or very nearly 1 : 1. Whence all, the water disregarded, may perhaps come under the above general formula.

Blomstrand finds 5 p. c tantalic acid in the Ytterby mineral.

Pyr., etc.—Fergusonite from Greenland gives in the closed tube a little water. B.B. infusible; on charcoal its color becomes pale yellow. With borax dissolves with difficulty, giving a yellow bead while hot, the insoluble portion being white; the saturated bead is yellowish-red, and is made opaque by flaming. Slowly dissolved by salt of phosphorus, leaving a white insoluble residue; in O.F. the bead is yellow, while in R.F. it is colorless, or, if saturated, slightly reddish, becoming opaque on cooling; treated with tin the bead remains uncolored, while the insoluble residue is made flesh-red. Decomposed by soda without dissolving, leaving a reddish slag; with soda on charcoal affords globules of metallic tin (Berzelius). When evaporated with sulphuric acid yields a white residue, which, treated with muriatic acid and metallic zinc, gives a bluish-green color Tyrite decrepitates and yields much water in the closed tube (Forbes).

Obs.—Fergusonite was discovered by Gieseckë, near Cape Farewell in Greenland, disseminated in quartz, and named after Robert Ferguson of Raith. Also found at Ytterby, Sweden, as mentioned above.

Tyrite is associated with euxenite at Hampemyr on the island of Tromoe, and Helle on the mainland; at Næskul, about ten miles east of Arendal.

484. ADELPHOLITE. Adelfolit *N. Nordenskiöld*, Beskrifn. Finl. Min., 1855, Jahrb. Min., 313, 1858; *A. E. Nord.*, Pogg., cxxii. 615, 1864.

Tetragonal. Angles undetermined.

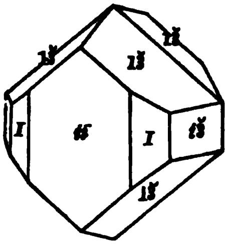
H.=3·5–4·5. G.=3·8. Lustre greasy. Color brownish-yellow to brown and black. Streak white or yellowish-white. Subtranslucent.

A columbate of iron and manganese, containing 41·8 p. c. of metallic acids, and 9·7 p. c. of water. From Laurinmäki in Tammela, Finland, with columbite.

485. MENGITE. Ilmenite *Brooke* Phil. Mag., x. 187, 1831. Mengit *G. Rose*, Reis. Ural, ii. 83, 1842.

Orthorhombic. $I \wedge I=100° 28'$, $O \wedge 1\text{-}\breve{i}=133° 42'$; $a : b : c=1·0463 : 1 : 1·2071$.

487



$O \wedge 1\text{-}\breve{\imath}=136° 50'$	$i\text{-}\breve{\imath} \wedge i\text{-}\breve{\imath}$, adj.,$=136° 20'$
$I \wedge i\text{-}\bar{\imath}=140\ 14$	$1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath}$, mac.,$=151\ 26$
$i\text{-}\bar{\imath} \wedge i\text{-}\breve{\imath}=111\ 50$	$1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath}$, brach.,$=101\ 1$

Occurs in short prisms, often terminated by four sided pyramids. No distinct cleavage.

H. = 5–5·5. G.=5·48. Lustre submetallic splendent, of surface of fracture subvitreous. Color iron-black. Streak chestnut-brown. Fracture uneven.

Comp.—Contains, according to G. Rose (l. c.), zirconia, oxyd of iron, and titanic acid.

Pyr., etc.—B.B infusible, but becomes magnetic. With salt of phosphorus, in the outer flame, gives a greenish-yellow clear glass; in the inner a yellowish-red, which is made deep red by adding tin. With soda a manganese reaction.

Obs.—Occurs in granite veins in the Ilmen mountains. The crystals are imbedded in albite, and the largest are but two or three lines long.

Brooke's name *Ilmenite* being preoccupied, Rose changed it to *Mengite*, after Menge, the discoverer of the mineral. The mengite of Brooke is monazite.

486. RUTHERFORDITE. *Shepard*, Am. Assoc., iv. 312, 1851, Am. J. Sci., II. xii. 209.

Monoclinic, with $I \wedge I=93°$, according to Shepard. In crystals and grains, without cleavage.

H.=5·5, Hunt. G.=5·58–5·69, Shepard; 5·55, Hunt. Lustre of fracture shining vitreo-resinous, and color blackish-brown. Opaque, but thin fragments translucent and smoky orange-brown by transmitted light. Streak and powder yellowish-brown, near fawn-color. Fracture conchoidal. Brittle.

Comp.—According to Shepard, contains titanic acid, oxyd of cerium, and possibly oxyd of uranium and yttria. According to some unfinished trials by T. S. Hunt (Am. J. Sci., II. xiv. 344), it contains probably 58·5 p. c. or more of titanic acid, with 10 p. c. of lime, with other ingredients undetermined.

Obs.—Occurs at the gold mines of Rutherford Co., North Carolina, along with rutile, brookite, zircon, and monazite.

3. PHOSPHATES, ARSENATES, ANTIMONATES, NITRATES.

A. PHOSPHATES, ARSENATES, ANTIMONATES.

In the anhydrous Phosphates and Arsenates the hardness is from 3 to 6; colors various, comprising, besides white or colorless, shades of green, yellow, blue, brown, violet, black, several of them bright; crystalline forms of each of the systems, except the isometric. The hydrous species have a still wider range of crystallization and colors, including the isometric system in the former, and reddish shades among the latter; while the limits of hardness are lower, being between 1 and 5; a much larger proportion of the species are clinohedral. In composition, the oxygen ratio for bases and acid which is far the most common, is 3 : 5; next to this

6 : 5; the ratios 2 : 3, 4 : 5, 3 : 2 are rare; while 1 : 1 is unknown, except problematically in two or three species of doubtful composition.

The pyrognostic reactions for phosphates B.B. are the following: If the acid is combined with a base which of itself imparts no color to the flame, it will give a characteristic bluish-green color, and this may be made more intense by moistening with sulphuric acid before ignition. If the phosphate is soluble in nitric acid, the dilute solution will give with acetate of lead a white precipitate, which after washing yields B.B. on charcoal in R.F. a crystalline polyhedral bead of phosphate of lead. Further, according to Bunsen, if a phosphate, or a substance containing but a small amount of phosphoric acid, be heated in a wide closed glass tube, with three parts of dry soda and a small fragment of sodium, it is on fusion converted into a phosphid, which after cooling yields phosphuretted hydrogen when moistened with water. Most phosphates in the state of powder are reduced to phosphids by simple fusion with sodium.

Arsenates are easily recognized by the alliaceous odor given when treated on charcoal, especially when fused with soda.

I. ANHYDROUS.

ARRANGEMENT OF THE SPECIES.

I. XENOTIME GROUP. O. ratio for bases and acid 3 : 5. Crystallization tetragonal.

490. XENOTIME	$\dot{Y}^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$(P\Theta)_2\vert\Theta_6\vert\bar{Y}_3$
491. CRYPTOLITE	$\dot{C}e^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$(P\Theta)_2\vert\Theta_6\vert\bar{C}e_3$

II. APATITE GROUP. Oxygen ratio for bases and acid 3 : 5, but with the addition of a fluorid or chlorid, which, if included with the bases, makes the ratio 10 : 15=2 : 3. Crystallization hexagonal. Formula A on the ratio 3 : 5, and B that of 2 : 3.

492. APATITE A	$3\dot{C}a^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}+Ca(Cl,F)$	$(P\Theta)_2\vert\Theta_6\vert\bar{C}a_3+\frac{1}{3}\bar{C}a(Cl_2,F_2)$
B	$(\frac{9}{10}\dot{C}a+\frac{1}{10}Ca(Cl,F))^{10}\overset{\cdot\cdot\cdot\cdot\cdot}{P}^3$	$P_6\Theta_4(Cl_2,F_2)\vert\Theta_{20}\vert\bar{C}a_{10}$
493. PYROMORPHITE A	$3\dot{P}b^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}+PbCl$	$(P\Theta)_2\vert\Theta_6\vert\bar{P}b_3+\frac{1}{3}\bar{P}bCl_2$
B	$(\frac{9}{10}\dot{P}b+\frac{1}{10}(PbCl))^{10}\overset{\cdot\cdot\cdot\cdot\cdot}{P}^3$	$P_6\Theta_4Cl_2\vert\Theta_{20}\vert\bar{P}b_{10}$
494. MIMETITE A	$3\dot{P}b^3\overset{\cdot\cdot\cdot\cdot\cdot}{As}+PbCl$	$(As\Theta)_2\vert\Theta_6\vert\bar{P}b_3+\frac{1}{3}PbCl$
B	$(\frac{9}{10}\dot{P}b+\frac{1}{10}(PbCl))^{10}\overset{\cdot\cdot\cdot\cdot\cdot}{As}^3$	$As_6\Theta_4Cl_2\vert\Theta_{20}\vert\bar{P}b_{10}$

III. WAGNERITE GROUP. O. ratio for bases and acid 3 : 5, but with the addition, in wagnerite, of a fluorid, which, if included with the bases, makes the ratio 4 : 5. Crystallization clinorhombic, with *I* ∧ *I*=91°–95°.

495. WAGNERITE A	$\dot{M}g^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}+MgF$	$(P\Theta)_2\vert\Theta_6\vert\bar{M}g_3+\bar{M}gF_2$
B	$(\frac{3}{4}\dot{M}g+\frac{1}{4}MgF)^4\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$(PF)\vert\Theta_4\vert\bar{M}g_2$
496. MONAZITE	$(\dot{C}e,\dot{L}a,\dot{D}i,\dot{T}h\tfrac{1}{2})^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$(P\Theta)_2\vert\Theta_6\vert(\bar{C}e,\bar{L}a\,\bar{D}i,\tfrac{1}{2}\bar{T}h)_3$
497 TURNERITE		

IV. TRIPLITE GROUP. O. ratio as in the Wagnerite group. Crystallization orthorhombic with *I* ∧ *I*=97°—101°.

498. TRIPHYLITE	$(\dot{F}e,\dot{M}n,\dot{L}i)^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$(P\Theta)_2\vert\Theta_6\vert(\bar{F}e,\bar{M}n,\bar{L}i_2)_3$

499. TRIPLITE A	$(\dot{\mathrm{Fe}}, \dot{\mathrm{Mn}})^3 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}} + \mathrm{R\,F}$	$(\mathrm{P\,\Theta})_2\|\Theta_6\ \|(\mathrm{Fe, Mn})_3 + \mathrm{R\,F}_2$
B	$(\frac{3}{4}(\dot{\mathrm{Fe}}, \dot{\mathrm{Mn}}) + \frac{1}{4}\mathrm{R\,F})^4 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$(\mathrm{P\,F})\ \|\Theta_4\ \|(\mathrm{Fe, Mn})_2$
500. HOPEITE		

V. BERZELIITE GROUP. O. ratio for bases and acid 2 : 8.

501. BERZELIITE	$(\dot{\mathrm{Ca}}, \dot{\mathrm{Mg}}, \dot{\mathrm{Mn}})^{10} \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}{}^3$	$\mathrm{As}_6\,\Theta_5\|\Theta_{20}\|(\mathrm{Ca, Mg, Mn})_{10}$

VI. CARMINITE GROUP. Contains sesquioxyds. Crystals orthorhombic.

502. CARMINITE	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}, \ddot{\mathrm{Fe}}, \dot{\mathrm{Pb}}$

VII. AMBLYGONITE GROUP. Contains alumina, lithia, and fluorine. Crystallization triclinic; $I \wedge I = 73° - 74°$.

503. AMBLYGONITE	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \ddot{\mathrm{Al}}, \dot{\mathrm{Li}}, \mathrm{F}$

VIII. HERDERITE GROUP.

Tetragonal. $O \wedge 1 = 138° 45'$; $a = 0{\cdot}6201$. Observed planes as in the annexed figure. $1 \wedge 1$, pyram., $= 124° 26'$; basal, $= 82° 30'$; $I \wedge 1 = 131° 15'$. Cleavage: I, perfect.

H.=4–5. G.=4·45–4·56; 4·557, Berz.; 4·54, Georgia, Smith. Lustre resinous. Color yellowish-brown, reddish-brown, hair-brown, flesh-red, grayish-white, pale yellow; streak pale brown, yellowish, or reddish. Opaque. Fracture uneven and splintery.

Comp.—$\dot{\mathrm{Y}}^3 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$=Phosphoric acid 37·86, yttria 62·14=100.

Analyses: 1, Berzelius (l. c.); 2, E. Zschau (Jahrb. Min. 1855, 518); 3, J. L. Smith (Am. J Sci., II. xviii. 378); 4, Damour (Bull. G. Fr., II. xiii. 542); 5, Wartha (Pogg., cxxviii. 166):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\ddot{\mathrm{Fe}}$	$\dot{\mathrm{Y}}$	$\dot{\mathrm{Ce}}$	
1. Hitteröe	33·49 [a]	—	62·58	—	, subphosph. iron 3·93=100 Berzelius.
2. "	30·74	*tr.*	60·25	7·98	, $\ddot{\mathrm{Si}}$ *tr.*=98·97 Zschau.

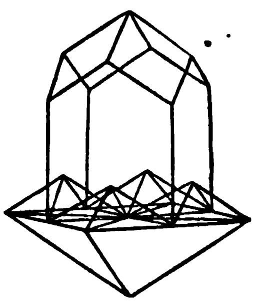
	$\ddot{\bar{P}}$	$\ddot{\bar{F}}e$	$\dot{Y}$	$\dot{C}e$	
3. Georgia	32·45	2·06	54·13	11·03[b],	$\ddot{Si}$ 0·89=100·56 Smith.
4. "	31·64	1·20[a]	60·40	——,	$\ddot{Ti}$, $\ddot{Zr}$ 7·40=100·64 Damour.
5. Wiserine	35·08	—	48·33	——,	specular iron, with trace $\ddot{Ti}$, 6·59=100 Wartha.

[a] With *tr.* of H F. [b] Includes a little La O, Di O. [c] Includes some U^2O^3.

Pyr., etc.—B.B. infusible. When moistened with sulphuric acid colors the flame bluish-green Difficultly soluble in salt of phosphorus. Insoluble in acids.

Obs.—From a granite vein at Hitterõe, with polycrase, malacon, and orthite, where the crystals are sometimes symmetrically compounded with crystals of zircon, as in the annexed figure (E. Zschau, Am. J. Sci., II. xx. 273), which is zircon above and xenotime below, the two species being closely isomorphous; at Ytterby, Sweden; the Fibir Berge, S.W. from St. Gothard; Binnenthal in Upper Valais, Switzerland (*wiserine*). In the United States, in the gold washings of Clarksville, Georgia (f. 438), associated with zircon, rutile, and cyanite; in McDowell Co., N. C.; in grayish-white and pale yellow crystals in the diamond sands of Bahia, Brazil (castelnaudite).

439



Beudant named the species *xenotime* (apparently from ξενός, *stranger to*, and τιμή, *honor*), but in the next line gives the derivation "κενός, *vain*, et τιμή, honneur," as if the word were *kenotime*, and adds afterward that his name is intended to recall the fact that the mineral was erroneously supposed by Berzelius (in 1815) to contain a new metal (the metal which he named thorium, before the later thorium was discovered). There is a sneer at the great Swedish chemist in the name, which should have occasioned its immediate rejection. Fortunately the word was misspelt from the first; and in its accepted form may be regarded as referring to the fact that the crystals are small, rare, not showy, and were long unnoticed.

491. CRYPTOLITE. Kryptolith *Wöhler*, Gel. Anz. Gött., 1846, 19, Pogg., lxvii. 424. Phosphocerite *H. Watts*, Qu. J. Ch. Soc., ii. 131, 1849.

In acicular prisms and minute grains; those of cryptolite perhaps hexagonal, Wöhler; those of phosphocerite tetragonal octahedrons and square prisms, Watts and Chapman.

G.=4·6, cryptolite; 4·78, phosphocerite. Color wine-yellow; of phosphocerite, pale sulphur-yellow or colorless. Transparent—translucent.

Comp.—$\dot{C}e^3\ddot{\bar{P}}$ (like monazite), the cerium replaced in part by didymium. The analysis of cryptolite affords better $\dot{C}e^{10}\ddot{\bar{P}}^3$. Analyses: Wöhler and Watts (l. c.):

	$\ddot{\bar{P}}$	$\dot{C}e$, $\dot{D}i$	$\dot{F}e$
1. Cryptolite	27·37	73·70	1·51=102·58 Wöhler.
2. Phosphocerite	29·66	67·38	$\ddot{\bar{F}}e$ 2·95=100 Watts.

The excess in anal. 1 is supposed to be due to oxydation of the protoxyd of cerium in the course of the analysis.

Pyr., etc.—Cryptolite is not altered by moderate heating. Soluble in concentrated sulphuric acid. Phosphocerite, according to Chapman, vitrifies partially on the edges, tinging the flame at the same time slightly green. Affords the reaction of phosphoric acid and also of cerium, producing, however, with borax and salt of phosphorus a glass which is pale violet-blue when cold, either due to the presence of didymium or a minute portion of cobalt ore.

Obs.—Cryptolite occurs in the green and red apatite of Arendal, Norway, and is discovered on putting the apatite in dilute nitric acid; constitutes 2 or 3 p. c. of the mass; it was found especially in the red apatite, or in reddish points of the green, and associated with particles of magnetic iron, hornblende, and another cerium ore of a hyacinth-red color, supposed to be monazite. This mineral was looked for in the yellowish apatites of Snarum without success. Occurs also with apatite in the Tyrol (?); and in the apatite of the Slüdianka in Siberia. Phosphocerite, according to Watts and Chapman, may be the grayish-yellow powder in the cobalt ore of Tunaberg. The crystalline forms most common in the powder are an octahedron and a square or rectangular prism, terminating in a four-sided pyramid parallel with the lateral planes, resembling fig. 248 under zircon. Genth has observed a mineral, probably cryptolite, in the Hurdstown apatite.

Named from κρυπτός, *concealed*.

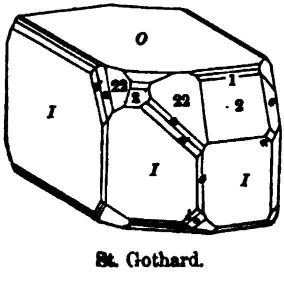
$I \wedge i\text{-}2 = 150°$

442



St. Gothard.

Cleavage: O, imperfect; I, more so. Also globular and reniform, with a fibrous or imperfectly columnar structure; also massive, structure granular.

H.=5, sometimes 4·5 when massive. G.=2·92—3·25. Lustre vitreous, inclining to subresinous. Streak white. Color usually sea green, bluish-green; often violet-blue; sometimes white; occasionally yellow, gray, red, flesh red, and brown; none bright. Transparent—

opaque. A bluish opalescence sometimes in the direction of the vertical axis, especially in white varieties. Cross fracture conchoidal and uneven. Brittle.

Var.—1. *Ordinary.* Crystallized, or cleavable and granular massive. (*a*) The *asparagus stone* (originally from Murcia, Spain) and *moroxite* (from Arendal) are ordinary apatite. The forme was yellowish-green, as the name implies; the latter was in greenish-blue and bluish crystals and the names have been used for apatite of the same shades from other places.

G.=3·211, fr. Ehrenfriedersdorf, in Saxony, G. Rose; emerald mine on the Tokovaia River Urals, 3·212, Koksch.; of Pargas (anal. 14) 3·19, Arppe; of Tammela, bluish-green (anal. 15). 3·18, Arppe; of Miask, yellow (anal. 17), 3·234, v. Rath; ib., 3·215, Alexejef; of Murcia, Spain, 3·235, Rose; of Arendal, Norway, 3·194, Rose; of Snarum, 3·174, Rose; of Greinor, Tyrol, 3·175, Rose; of St. Gothard, 3·197, Rose.

The above measurements are by Kokscharof, on crystals from the emerald mine on the Tokovaia, a fluor-apatite (anal. 27). According to him, apatite from Achmatovsk, and that of L. Laach, affords $O \wedge 1 = 139° 54'$ and $1 \wedge 1 = 142° 25'$; that from Blagodat, 139° 44′ and 142° 18½′; that from Murcia, 139° 47′ and 142° 20′; that of St. Gothard, 142° 19′; that of Ehrenfriedersdorf the same as that from the Tokovaia emerald mine.

(*b*) *Lasurapatite* is a sky-blue variety; it occurs in crystals with lapis-lazuli at Bucharei in Siberia. (*c*) *Francolite*, from Wheal Franco, near Tavistock, Devonshire, occurs in small crystalline stalactitic masses, grayish-green to brown, and in minute curving crystals.

2. *Fibrous, concretionary, stalactitic.* The name *Phosphorite* was used by Kirwan for all apatite, but in his mind it especially included the fibrous concretionary and partly scaly mineral from Estremadura, Spain, and elsewhere. It has H.=4·5; G.=2·92—3, Forbes, but 2·98—3·12 after ignition. Eupyrchroite (from Crown Point, N. Y.) belongs here; it is concentric in structure, consisting of convex subfibrous layers, more or less easily separable; H.=4½; G.=3·053; ash-gray and bluish-gray in color, and gives a green phosphorescence when heated (whence the name, from εὖ, *well*, πῦρ, *fire*, and χρόα, *a color*.

3. *Earthy apatite; Osteolite.* Mostly altered apatite (see beyond). Coprolites are mainly impure phosphate of lime.

4. *Fluor-apatite.* 5. *Chlor-apatite.* Apatite also varies as to the proportion of fluorine to chlorine, one of these elements sometimes replacing nearly or wholly the other.

Pseudoapatite of Breithaupt is pseudomorphous apatite from Kurprinz, near Freiberg, and Schlackenwald in Bohemia.

Comp.—Phosphate of lime, with chlorid or fluorid of lime, or both; $\dot{C}a^3\ddot{P} + \frac{1}{3}Ca(Cl, F)$; or $(\frac{9}{10}\dot{C}a + \frac{1}{10}Ca(Cl, F))^{10}\ddot{P}^3 =$, for *chlor-apatite*, Phosphoric acid 40·92, lime 48·43 (=89·35 $\ddot{P}$, $\dot{C}a$), chlorine 6·81, calcium 3·84 (=10·65 Cl, Ca); and for *fluor-apatite*, $\ddot{P}$ 42·26, $\dot{C}a$ 50·00 (=92·26 $\ddot{P}$, $\dot{C}a$), F 3·77, Ca 3·97 (=7·74 F, Ca); and the analyses should give for the former $\ddot{P}$ 40·92, $\dot{C}a$ 53·81, Cl 6·81; for the latter $\ddot{P}$ 42·26, $\dot{C}a$ 55·56, F 3·77 (Rammelsberg). In most kinds both fluorine and chlorine are present. The amount of fluorine has not been determined with accuracy; in the larger part of the analyses it has been deduced from the loss; and where this is the case, the amount of fluorine is not given in the table of analyses beyond. G. Rose first detected the fluorine and chlorine, and published the following as the composition of different specimens (Pogg., ix. 185):

	1. Snarum, Norway.	2. Murcia, Spain.	3. Arendal, Norway	4. Greiner, Tyrol.	5. St. Gothard, Tyrol.
Phosphate of lime	91·13	92·066	92·189	92·16	92·31
Chlorid of calcium	4·28	0·885	0·801	0·15	*tr.*
Fluorid of calcium	4·59	7·049	7·01	7·69	7·69

[a] With some Mg O and Fe O. [b] With some alumina.

The earliest examination of apatite was that of Proust, in 1788 (l. c.), on the phosphorite of Estremadura, which led him to call it a *calcareous phosphate*; and that of Klaproth, in the same year (l. c.), on the Saxon apatite, in which he found P̈ 45, Ċa 55. Pelletier in 1790 (l. c.) made a complete, although not entirely accurate, analysis of the phosphorite, detecting even the fluorine and chlorine, obtaining P̈ 34, Ċa 59, fluoric acid 2·5, muriatic acid 0·5, F̶e 1. S̈i 2, C̈ 1=100. The asparagus stone of Spain was not analyzed until 1798, by Vauquelin (l. c.); he found only phosphoric acid and lime, respectively 45·72 and 54·28 p. c. His results proved its identity with the Saxon mineral, and from this time they were united, along with phosphorite, under Werner's name of *apatite*, first given in 1786 to the Saxon mineral.

Forbes found in the eupyrchroite (Phil. Mag., IV. xxix 340) P̈ 44·12. Phosphorite of different localities has afforded a trace of iodine, and that from Amberg gave H. Reinsch in addition a trace of *bromine.* Apatite from Krageröe, according to Völcker (anal. 11), contains no fluorine. That of Jumilla afforded de Luna 1·75 p. c. of cerium, lanthanum, and didymium.

Near Coquimbo, Chili, at the mines of Tambillos, occur clear turquois-blue crystals, containing, according to F. Field (Chem. Gaz., No. 400, 1860, p. 224), P̈ 37·69, Ċa 36·64, Ċu 20·93 Ca C̶l 2·38, Ḣ 2·32=99·91, the copper being present as phosphate.

Lechartier has shown (C. R., lxv. 172) that an arsenic acid apatite may be made by fusion together of arsenate of lime and chlorid of calcium; and that from the same at a lower temperature an arsenic acid wagnerite is obtained in crystals.

Pyr., etc.—B.B. in the forceps fuses with difficulty on the edges (F.=4·5—5), coloring the flame reddish-yellow; moistened with sulphuric acid and heated colors the flame pale bluish-green (phosphoric acid); some varieties react for chlorine with salt of phosphorus, when the bead has been previously saturated with oxyd of copper, while others give fluorine when fused with this salt in an open glass tube. Gives a phosphid with the sodium test.

Dissolves in muriatic and nitric acid, yielding with sulphuric acid a copious precipitate of sulphate of lime; the dilute nitric acid solution gives with acetate of lead a white precipitate, which B.B. on charcoal fuses, giving a globule with crystalline facets on cooling. Some varieties of apatite phosphoresce on heating.

Obs.—Apatite occurs in rocks of various kinds and ages, but is most common in metamorphic crystalline rocks, especially in granular limestone, granitic and many metalliferous veins, particularly those of tin, in gneiss, syenite, hornblendic gneiss, mica schist, beds of iron ore; occasionally in serpentine, and in igneous or volcanic rocks; sometimes in ordinary stratified limestone, beds of sandstone or shale of the Silurian, Carboniferous, Jurassic, Cretaceous, or Tertiary formations. It has been observed as the petrifying material of wood.

Among its localities are Ehrenfriedersdorf in Saxony, Schwarzenstein and Pfitsch in the Tyrol; region of St. Gothard in Switzerland; Mussa-Alp in Piedmont, white or colorless, and of like form and color on the Mittaghorn in Upper Valais; Rabenstein and Amberg in Bavaria; Ziar wald and Schlackenwald in Bohemia; in England, in Cornwall, with tin ores; in Cumberland, a. Carrock Fells, in celandine-green crystals in gilbertite; in Devonshire, cream-colored at Bovey Tracey, and at Wheal Franco (*francolite*): in Ireland, in a basaltic dike near Kilroot in Antrim also in Down, Dublin, and Killiney Hill. The greenish-blue variety, called *moroxite*, occurs at Arendal, Snarum, and Krageröe in Norway, at the latter place in hornblendic gneiss, in part flesh-red, and looking much like feldspar; with magnetic iron of a greenish-yellow color at Mt. Blagodat in the Ural; with black tourmaline on the Schaitanka in Katharinenburg; on the Sl..dianka (*lasurapatite*) at the emerald mine of the Takovaia, 85 versts N. E. of Katharinenburg on the Kiräba, 70 versts S. W. of Miask, containing *no* chlorine (Pusirevsky), with G.=3·126; in Pargas, Finland. The *asparagus stone* or *spargelstein* of Jumilla, in Murcia (not C. de Gata), Spain, is pale yellowish-green in color; and a variety from Zillerthal is wine-yellow. The *phosphorite*, or massive radiated variety, is obtained abundantly near the junction of granite and argillite, in Estremadura, Spain; at Schlackenwald in Bohemia; at Krageröe, whence it has been largely exported to England; at Amberg, in Jurassic limestone, nodular and stalactitic.

In *Maine*, on Long Island, Blue-hill Bay, in veins 10 in. wide, intersecting granite. In *N. Hamp.*, crystals, often large, are abundant, 4 m. S. of the N. village meeting-house, Westmoreland, in a vein of feldspar and quartz, in mica slate, along with molybdenite; fine crystals at Piermont, in white limestone, on the land of Mr. Thomas Cross. In *Mass.*. crystals occasionally 6 in long, at Norwich (N. E. part), in gray quartz; at Bolton abundant, the forms seldom interesting; sparingly at Chesterfield, Chester, Sturbridge, Hinsdale, and Williamsburgh. In *New York*, large crystals of apatite are found in St. Lawrence Co., in granular limestone, with scapolite, sphene, etc.; one crystal from Robinson's farm, in Hammond, was nearly a foot in length, and weighed 18 lbs.; in crystals 1 m. S. E. of Governeur and 2 m. N.; in Rossie, with sphene and pyroxene, 2 m. N. of the village of Oxbow; also on the bank of Vrooman Lake, Jefferson Co., in white limestone, green prisms ½–5 in. long; Sanford mine, East Moriah, Essex Co., in magnetic iron ore, which is often thickly studded with six-sided prisms; also at Long Pond, Essex Co.; near Edenville, Orange Co., in prisms ¼–12 in. long, bright asparagus-green, in white limestone; in the same region, blue, grayish-green, and grayish-white crystals; 2 m. S. of Amity, emerald- and bluish-green crystals; at Long Pond, Essex Co., with garnet and idocrase; at Greenfield, Saratoga Co., St. Anthony's Nose, and Corlaer's Hook, less interesting; fibrous mammillated (*eupyrchroite*) at Crown Point, Essex Co., about a mile south of Hammondsville, in large quantities, quarried for agricultural purposes. In *New Jersey*, on the Morris Canal, near Suckasunny, of a brown color, in massive pyrrhotite; with the magnetite of Bryam mine; Mt. Pleasant mine near Mt. Teabo, in a low hill near the junction of Rockaway R. and Burnt Meadow Cr., ¾ m. from the canal, in masses sometimes 6 in. through; at Hurdstown, Sussex Co., where a shaft has been sunk and the apatite mined; masses brought out weigh occasionally 200 lbs., and some cleavage prisms have the planes 8 in. wide. In *Penn.*, at Leiperville, Delaware Co.; in Chester Co.. at New Garden; in Bucks Co., at Southampton. In *Maryland*, near Baltimore. In *Delaware*, at Dixon's quarry, Wilmington, of a rich blue color.

In *Canada*, in North Elmsley, and passing into South Burgess, in an extensive bed 10 ft. broad, 3 ft. of which are pure sea-green apatite, and outside of this mixed with limestone, and sometimes occurring in prisms a foot long and 4 in. through, with pyroxene and phlogopite—a *fluor-apatite* containing only 0·5 chlorine (Hunt); similar in Ross; at the foot of Calumet Falls, in blue crystals; also near Blaisdell's mill on the Gatineau; in crystals in doleryte; at St. Roch, on the Achigan, clear rose-red, amethystine, and colorless crystals, with augite.

Apatite was named by Werner from ἀπατάω, *to deceive*, older mineralogists having referred it to aquamarine, chrysolite, amethyst, fluor, schorl, etc.

For recent articles on cryst., Kokscharof, Min. Russl., ii. 39, 189, iii. 86; v. Rath, Pogg., cviii. 353; Pfaff, Pogg., cxi. 276; Hessenberg, Min. Not., Nos. ii. and iv.

Alt.—492A. OSTEOLITE is massive impure altered apatite, as stated by A. H. Church (Ch. News, xvi. 150, 1867), after analyses of specimens from various localities. The ordinary compact variety looks like lithographic stone of white to gray color. It also occurs earthy. H.=1—2. G.=2·8—3·1, fr. Hanau, Bromeis; 2·86, fr. Hanau, Church; lustre feeble or wanting. Excepting impurities, it has the composition of apatite, although most analyses, excepting those of Church, have not detected the fluorine or chlorine.

Analyses: 1–3, Bromeis, Rütz, and Ewald (Ann. Ch. Pharm., lxxix. 1); 4, Schröder (ib., lxxxix. 221, ci. 283); 5, Durré (Pogg., cv. 155):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dot{\mathrm{Ca}}$	$\ddot{\mathrm{Si}}$	$\overset{\cdot\cdot\cdot}{\bar{\mathrm{Al}}}$	$\overset{\cdot\cdot\cdot}{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\ddot{\mathrm{C}}$	$\dot{\mathrm{H}}$
1. Hanau	36·88	49·41	4·50	0·93	1·85	0·47	0·62	0·76	1·81	2·28=99·51 Bromeis.
2. "	37·41	49·24	2·75	1·25	2·78	0·79	0·46	0·81	2·34	3 45=101·28 Rütz.
3. "	37·16	48·20	2·03	*tr.*	2·31	1·85	0·43	0·78	2·55	3 63=98·80 Ewald.
4. Redwitz?	42·00	48·16	4·97	—	1·56	0·75	0·02	0·04	2·21	1 31=101·02 Schröder.
5. Schönwald	34·64	44·76	8·89	6·14	0·50	0·79	—	—	—	2·97, Cl *tr.*=98·69 D.

No. 1 was of the compact part; 2, of the earthy; 3, of the intermediate. Klaproth found in an earthy apatite from Siegeth, Hungary (Beitr., iv. 373), 2·5 p. c. of fluoric acid. A kind from a bed in the Tertiary formation of the Fichtelgebirge, white and earthy, with G.=2·82, gave Schmidt (B. H. Ztg., xx. 390) 76 p. c. $\dot{C}a^3\ddot{\bar{P}}$. Church found the white, hard osteolite of Eichen, Hanau, to afford much fluorine, and more lime than would saturate the phosphoric and carbonic acids; whence he deduces from his analysis $\dot{C}a^3\ddot{\bar{P}}$ 87·25, $\dot{C}a\,\ddot{C}$ 5·70, Ca F 4·92, $\dot{H}$ 2·34=100·21, making it true apatite.

Found in fissures or cavities in doleryte or related rocks, as if a secondary product; also in beds among stratified rocks.

Occurs at Ostheim, near Hanau (G.=2·89—3·08), and near Schönwald in Bohemia (G.=2·828), in doleryte; at Redwitz? in the Fichtelgebirge (G.=2·89, 2·82). It is named from ὀστέον, *bone*, and λίθος, bones consisting largely of the same phosphate.

492B. **Phosphatic Nodules. Coprolites.** Phosphatic nodules occur in many fossiliferous rocks, which are probably in all cases of organic origin. They sometimes present a spiral or other interior structure, derived from the animal organization that afforded them, and in such cases their coprolitic origin is unquestionable. In other cases there is no structure to aid in deciding whether they are true coprolites or not. The following are analyses of some coprolites:

	1. Burdiehouse.	2. Fifeshire.	3. Burdiehouse.	4. Burdiehouse.	5. Koschtitz.	6. Oberlaugenau.
Phosphate of lime	9·58	63·60	85·08	83·31	50·89	15·25

	100·01	97·45	100·15	100·18	99·03	100·00

Nos. 1 and 2, by Gregory and Walker; 3 and 4, by Connell; 5, by Quadrat; 6, Rochleder. See other analyses by R. Hoffmann, J. pr. Ch., xc. 469.

Phosphatic nodules, from the Lower Silurian rocks of Canada, contain sometimes fragments of shells of Lingula and Orbicula, which shells, unlike most others, consist largely of phosphates. They are found in the Chazy formation at Allumette Id. (G.=2·875), Hawkesbury, R. Ouelle (G.=3·15), and elsewhere. They have afforded T. S. Hunt (Logan's Rep. Can., 1851–52, 1863, and Am. J. Sci., II. xvii. 235, 1854) the following results:

	Allumette I.	Hawkesbury.	R. Ouelle.
Phosphate lime	36·38	44·70	40·34
Carb. lime, with some fluorid	5·00	6·60	5·14
Carb. magnesia	——	4·76	9·70
Sesquiox. iron and little $\ddot{\bar{A}}l$	[7·02]	8·60	12·62
Magnesia		——	——
Insol.	49·90	27·90	25·44
Volatile	1·70	5·00	2·13
	100·00	97·56	95·37

They are blackish externally, and yellowish-brown to blackish-brown or bluish-brown within. A phosphatic nodule, in brown coal beds near Roth, afforded Hassencamp (Jahrb. Min. 1856, 422) Phosph. lime 45·57, ph. magn. 2·04, ph. iron 27·71, magnesia 1·34, lime 4·20, alumina 0·63, organic acid 3·33, water 7·50, $\ddot{C}$ and loss 7·68=100. H.=2·5; G.=2·318. Color externally pitch-black; within, honey-yellow.

492C. *Staffelite* of Stein (Jahrb. Min. 1866, 716) occurs incrusting the phosphorite of Staffel, in botryoidal, reniform, or stalactitic masses, fibrous and radiating. H.=4. G.=3·1284. Color leek to dark green, greenish-yellow. Analysis afforded Forster (l. c.) $\ddot{\bar{P}}$ 39·05, $\ddot{C}$ 3·19, $\ddot{\bar{A}}l$ 0·026, $\dot{F}e$ 0·037, $\dot{C}a$ 54·67, F 3·05, $\dot{H}$ 1·40=101·423. Stein regards it as a result of the action of carbonated waters on phosphorite.

492D. GUANO. Guano is bone-phosphate of lime, or osteolite, mixed with the hydrous phosphate, brushite, and generally with some carbonate of lime, and often a little magnesia, alumina, iron, silica, gypsum, and other impurities. It often contains 9 or 10 p. c. of water. It is often granular or oolitic; also compact through consolidation produced by infiltrating waters, in which case it is frequently lamellar in structure, and also occasionally stalagmitic and stalactitic. Its colors are usually grayish-white, yellowish and dark brown, and sometimes reddish, and the lustre of a surface of fracture earthy to resinous. Shepard's *Pyroclasite* (Am. J. Sci., II xxii. 97) is nothing but the hard guano from Monk's Island, Caribbean sea, the mass of which he named *Pyroguanite*, under the wrong idea of its having undergone the action of heat: and Phipson's *Sombrerite* (J. Ch. Soc., xv. 277, 1862) is the same thing from Sombrero, as shown by A. A. Julien (Am. J. Sci., II. xxxvi. 423). The waters which have filtrated through the guano at Sombrero have altered the coral rock adjoining, turning it more or less completely into phosphate of lime of a yellowish or brownish color; and phosphatic stalagmites and stalactites resinous in fracture are common.

Shepard's massive *Glaubapatite*, yellowish-brown to chocolate-brown in color, and in fibrous stalactites, from Monk's Island (l. c.), is also in all probability merely the guano rock above described. He says the mineral contains 15·1 p. c. of sulphate of soda, with 74·0 of phosphate of lime, and 10·3 of water; but such a compound is hardly a possibility, and the fact of its existence needs confirmation. The name, from glauber and apatite, alludes to the composition. The mineral includes also "tabular crystals," which may possibly be *brushite*, although the composition is against it.

492E. EPIPHOSPHORITE *Breith.* (B. H. Ztg., xxv. 194). Occurs reniform, of scaly-granular structure, inclining to fibrous, vitreous lustre, leek- to celandine-green color, with H.=4·5–5, G.=3·125 According to Richter it fuses with much difficulty, and affords indications of phosphoric acid, lime, protoxyd of iron, alumina, and a very little silica; not tested for fluorine or chlorine, because of too little material. Occurs with garnets and graphite in a crystalline rock, but locality unknown.

492F. TALC-APATITE *Hermann* (J. pr. Ch., xxxi. 101). An apatite from chlorite slate in the Schischimskian mountains, near Slatoust, containing a large percentage of magnesia in place of part of the lime, and low in specific gravity. It occurs in 6-sided prisms, grouped or single: H.=5; G.=2·7–2·75; lustre dull to earthy; color milk-white, yellowish externally; feebly translucent.

Composition, according to Hermann (l. c.), excluding 9·50 of insoluble material as impurities: $\ddot{\bar{\mathrm{P}}}$ 43·11, $\dot{\mathrm{C}}\mathrm{a}$ 41·44, $\dot{\mathrm{M}}\mathrm{g}$ 8·55, $\bar{\mathrm{F}}\mathrm{e}$ 1·10, Cl 0·92, $\dddot{\mathrm{S}}$ 2·32, fluorine undetermined; whence the formula $3\,\dot{\mathrm{C}}\mathrm{a}^3\,\ddot{\bar{\mathrm{P}}} + \dot{\mathrm{M}}\mathrm{g}^3\,\ddot{\bar{\mathrm{P}}}$, with chlorid and fluorid. Berzelius suggests that the magnesia may have come from the gangue. According to Volger it is an altered impure apatite. Some magnesia is present in many apatites (Bischof.).

492G. HYDROAPATITE *Damour* (Ann. d. M., V. x. 65). In mammillary concretions, looking a little like chalcedony. H.=5·5, G.=3·10. Color milk-white. Subtransparent. Composition that of a *hydrous apatite*; $3\,\dot{\mathrm{C}}\mathrm{a}^3\,\ddot{\bar{\mathrm{P}}} + \mathrm{Ca\,F} + \dot{\mathrm{H}}$. Analysis by Damour (l. c.):

$\ddot{\bar{\mathrm{P}}}$ 40·00 $\dot{\mathrm{C}}\mathrm{a}$ 47·31 F 3·36 Ca 3·60 $\dot{\mathrm{H}}$ 5·30.

Heated in a tube it decrepitates and gives out ammoniacal water.

Found near St. Girons in the Pyrenees, in the fissures of a brownish, ferruginous, argillaceous schist, a rock which not far distant affords wavellite.

493. PYROMORPHITE. Grön Blyspat, Minera plumbi viridis pt., *Wall.*, Min., 296, 1748. Mine de Plomb verte *Fr. Trl.* Wall., i. 536, 1853. Hexagonal. $O \wedge 1 = 139° \ 38'$; $a = 0·7362$. Observed planes: O, I, i-2, 1, 2, 4, 2-2.

$O \wedge 4 = 106° \ 23'$ $O \wedge 2\text{-}2 = 124° \ 11'$ $1 \wedge 1$, pyr., $= 142° \ 12'$

$O \wedge 2 = 120 \ \ 28$ $I \wedge i\text{-}2 = 150$ $I \wedge 2\text{-}2 = 135 \ \ 46$

Cleavage: *I* and 1 in traces. *I* commonly striated horizontally. Often globular, reniform, and botryoidal or verruciform, with usually a subcolumnar structure; also fibrous, and granular.

H.=3·5—4. G.=6·5—7·1, mostly when without lime; 5—6·5, when containing lime. Lustre resinous. Color green, yellow, and brown, of different shades; sometimes wax-yellow and fine orange-yellow; also grayish-white to milk-white. Streak white, sometimes yellowish. Subtransparent—subtranslucent. Fracture subconchoidal, uneven. Brittle.

Var.—1. *Ordinary.* (*a*) *In crystals.* J. Schabus found the angles 1 ∧ 1, in green crystals from Zschopau, =142°-26′ and 80° 11′; and in brown from Bleistadt, 142° 14′ and 80° 40′ (Pogg., c. 300). (*b*) In *acicular* and *moss-like* aggregations. (*c*) *Concretionary* groups or masses of crystals, having the surface angular. (*d*) *Fibrous.* (*e*) *Granular massive.* (*f*) *Earthy;* incrusting.

2. *Polysphærite.* Containing lime; color brown of different shades, yellowish-gray, pale yellow to nearly white; streak white; G.=5·89—6·44. Rarely in separate crystals; usually in groups, globular, mammillary, verruciform. *Miesite*, from Mies in Bohemia, is a brown variety. *Nussierite* is similar and impure, from Nussière, near Beaujeu, France; color yellow, greenish, or grayish; G.=5 0415. *Cherokine* is milk-white or pinkish-white in color, and occurs in slightly acuminated prisms, and also botryoidal and massive; G.=4·8 (?); from the Canton mine, Cherokee Co., Georgia. 3. *Chromiferous;* color brilliant red and orange. 4. *Arseniferous;* color green to white; G.=5·5—6·6. 5. *Pseudomorphous;* (*a*) after galenite; (*b*) cerussite.

Both the green and brown colors occur amoug the pure phosphates of lead, as well as those containing lime.

Comp.—3 $\dot{\mathrm{P}}\mathrm{b}^3\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+\mathrm{Pb\,Cl}$, or $(\frac{9}{10}\dot{\mathrm{P}}\mathrm{b}+\frac{1}{10}\mathrm{Pb\,Cl})^{10}\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}{}^3$, with lime often replacing part of the lead, fluorid of calcium part of the chlorid of lead, and arsenic acid sometimes part of the phosphoric acid, =Phosphoric acid 15·7, oxyd of lead 74·1, chlorine 2·6, lead 7·6=Phosphate of lead 89·8, chlorid of lead 10·2=100. Hunt found the cherokine (a specimen received from Shepard) to consist of *lead* and *phosphoric acid*, with less than 1 p. c. of other material (Am. J. Sci., II. xxiv. 275).

Specimens of pyromorphite from Huelgoet are often mixed with plumbogummite, and contain alumina up to 16 p. c. (Damour, Ann. d. M., III. xvii. 191, 1840).

Pyr., etc.—In the closed tube gives a white sublimate (chlorid of lead). B.B. in the forceps fuses easily (F.=1·5), coloring the flame bluish-green; on charcoal fuses without reduction to a globule, which on cooling assumes a crystalline polyhedral form, while the coal is coated white from chlorid, and, nearer the assay, yellow from oxyd of lead. With soda on charcoal yields metallic lead; some varieties contain arsenic, and give the odor of garlic in R.F. on charcoal. With salt of phosphorus, previously saturated with oxyd of copper, gives an azure-blue color to the flame when treated in O.F. (chlorine). Soluble in nitric acid.

Obs.—Pyromorphite occurs principally in veins, and accompanies other ores of lead.

Occurs at Poullaouen and Huelgoet in Brittany: at Zschopau and other places in Saxony; at Przibram, Mies, and Bleistadt, in Bohemia; at Sonnenwirbel near Freiberg; Clausthal in the Harz; in fine crystals at Nassau; Beresof in Siberia; Cornwall (green and brown), Devon (gray), Derbyshire (green and yellow), Cumberland (golden-yellow), in England; Leadhills (red and orange formerly), in Scotland; Wicklow (clove-brown and yellowish-green) and elsewhere, Ireland.

Pyromorphite has been found in good specimens at the Perkiomen lead mine near Philadelphia, and very fine at Phenixville; also in Maine, at Lubec and Lenox; in New York, a mile south of Sing Sing; sparingly at Southampton, Massachusetts, and Bristol, Conn.; in good crystallizations of bright green and gray colors, in Davidson Co., N. C.

Named from πῦρ, *fire*, μορφή, *form*, alluding to the crystalline form the globule assumes on cooling. This species passes into the following.

Alt.—Occurs altered to galenite (Pb S), cerusite ($\dot{P}b\ddot{C}$), calamine ($\dot{Z}n^2\dddot{S}i+\dot{H}$), calcite, and limonite; to galenite, probably through the action of sulphuretted hydrogen.

4. Horhausen	86·70	2·15	——	——	10·40=98·25 Dufrénoy.
5 Cornwall	84·55	4·50	——	——	9·05=98·10 Dufrénoy.
6. Cumberland, *Campylite*	71·70	19·00	——	——	9·45=100·15 Ramm.
7. Siberia G.=6·653	76·78	13·94	——	——	9·33=100 Struve.
8. Longban, *Hedyphane*	60·10	——	12·98	15·51	10·29=98·88 Kersten.

Michaelson found for the Longban hedyphane $\ddot{\bar{\mathrm{P}}}$ 3·19, $\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 28·51, $\dot{\mathrm{P}}\mathrm{b}$ 57·45, $\dot{\mathrm{C}}\mathrm{a}$ 10·50, Cl 3·06—2·93, corresponding to Pb Cl 11·70 (J. pr. Ch., xc. 108). Ratio of $\ddot{\bar{\mathrm{P}}}$ to $\ddot{\bar{\mathrm{A}}}\mathrm{s}$ in campylite, anal. 6, 1 : 3¼ (0·50 $\dot{\mathrm{C}}\mathrm{a}$ above removed); in anal. 7, 1 : 5; in hedyphane 1 : 2; and of $\dot{\mathrm{C}}\mathrm{a}$ to $\dot{\mathrm{P}}\mathrm{b}$ in the last 4 : 3.

Domeyko obtained for an impure, earthy, yellow mimetite, from Mina Grande, near Arqueros in Chili (Ann. d. M., IV. xiv. 145), $\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 11·55, $\ddot{\bar{\mathrm{P}}}$ 5·13, $\ddot{\mathrm{V}}$ 1·86, $\dot{\mathrm{P}}\mathrm{b}$ 58·31, $\dot{\mathrm{C}}\mathrm{a}$ 7·96, $\dot{\mathrm{C}}\mathrm{u}$ 0·92, Pb Cl 9·05, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$, $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 1·1, clay 2, $\dot{\mathrm{H}}$ 1·12=99·00. Domeyko does not cite this analysis in the last edition of his mineralogy (1860). It is associated with a vanadate of lead and copper.

Pyr., etc.—In the closed tube like pyromorphite. B.B. fuses at 1, and on charcoal gives in R.F. an arsenical odor, and is easily reduced to metallic lead, coating the coal at first with chlorid of lead, and later with arsenous acid and oxyd of lead. Gives the chlorine reaction as under pyromorphite. Soluble in nitric acid.

Obs.—Occurs at Wheal Unity, near Redruth in Cornwall, and at several other of the Cornish mines; also at Beeralston in Devonshire; Roughten Gill, Drygill, etc., in Cumberland· formerly at Leadhills and Wanloch Head in Scotland. At St. Prix in the Department of the Saone, in France, in capillary crystals; at Johanngeorgenstadt, in fine yellow crystals; at Nertschinsk, Siberia, in reniform masses, brownish-red; also at Zinnwald, and Badenweiler. The crystals from Preobragansk Bergwerk, Siberia, were black externally, having a coating of pyrolusite, but yellow within. At the Brookdale mine, Phenixville, Pa., crystals of pyromorphite capped with mimetite

Named from μιμητὴς, *imitator*, it closely resembling pyromorphite. Beudant's word *mimetese* is inadmissible, because wrongly formed. Shepard's modification of it, *mimetene*, he has rejected for *mimetite* in his last edition. *Mimetite* is the correct form in view of the derivation. Mohs united this species with pyromorphite.

Artif.—Formed by fusing together arsenate and chlorid of lead, and dissolving out afterward the excess of chlorid (Lechartier, C. R., lxv. 172).

495. WAGNERITE.

Wagnerit, Phosphorsaurer Talk, *Fuchs*, Schw. J, xxxiii. 269, 1821. Magnésie phosphatée *Fr.* Pleuroklas *Breith.*, Char., 50, 193, 1823.

Monoclinic. $C=71°\ 53'$, $I \wedge I=95°\ 25'$, $O \wedge 1\text{-}\grave{\imath}=144°\ 25'$, B. & M.; $a:b:c=0·78654:1:1·045$.

4. R. Chico	28·6	——	——	45·7	24·1	——	——, insol. 1·6=100 Damour.

[a] Includes also Di O.

Thoria was detected in monazite both by Berzelius and Wöhler, though not by Hermann. Tin was detected, with the blowpipe, by Rose in the American monazite.

Shepard found in his edwardsite (l. c.) 7·77 p. c. zirconia, 4·44 $\dddot{\text{A}}\text{l}$, 3·33 $\ddot{\text{S}}\text{i}$, with 56·53 $\dot{\text{C}}\text{e}$, $\dot{\text{L}}\text{a}$, and 26·66 $\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$; but rejects his results in the last edition of his Mineralogy, referring both edwardsite and eremite to monazite.

Var.—The crystal affording the author the above angles (f. 447) was a fine one with polished faces, well calculated for accurate measurements.* Hermann gives the angle $I \wedge I=92° 30'$; Breithaupt, 94° 35'.

Descloizeaux obtained for crystals from the auriferous sands of R. Chico, in Antioquia (Ann. Ch. Phys., III. li. 445), $I \wedge I=93° 20'$, $I \wedge i\text{-}\bar{i}=136° 30'$, 76° 15', $i\text{-}\bar{i} \wedge -1\text{-}\bar{i}=127°$, $O \wedge -1\text{-}\bar{i}=129° 30'$, $-1 \wedge -1=107°$ (nearly), $-1 \wedge 1\text{-}\bar{i}=143° 40'$. Kokscharof has measured crystals from Mt. Ilmen and the river Sanarka, and found $I \wedge I=93° 22'$, $C=76° 14'$, $O \wedge 2\text{-}\bar{i}=119° 10'$, $O \wedge 1\text{-}\bar{i}=138° 9'$, $1 \wedge 1=119° 28'$, $-1 \wedge -1=106° 44'$, $O \wedge 1\text{-}\bar{i}=143° 2'$, $O \wedge -1\text{-}\bar{i}=129° 59'$; the faces were not very even, and his results, he states, were therefore not very exact.

Pyr., etc.—B.B. infusible, turns gray, and when moistened with sulphuric acid colors the flame bluish-green. With borax gives a bead yellow while hot and colorless on cooling; a saturated bead becomes enamel-white on flaming. Difficultly soluble in muriatic acid.

Obs.—Monazite was first brought by Fiedler from the Ural. It occurs near Slatoust in the Ilmen Mtn., in granite, along with flesh-red feldspar; also near the river Sanarka, in the Ural; near Nöterö in Norway (*urdite*), in crystals sometimes 1 in. across; at Schreiberhau, with gadolinite (G.=4·9). In the United States it is found in small crystals from $\frac{1}{16}$ to $\frac{1}{4}$ in. long, with the sillimanite of Norwich, and sparingly with the same mineral at Chester, Ct. A few minute crystals (*eremite* of Shepard) were found in a boulder of albitic granite, containing also a few minute zircons and tourmalines, in the northeastern part of Watertown, Ct. Good crystals are obtained with the sillimanite of Yorktown, Westchester Co., N. Y.; near Crowder's Mountain, N. C.; and in gold washings on Todd's branch, Mecklenburg Co., N. C., with garnet, zircon, and diamond Found also in the gold washings of Rio Chico, in Antioquia.

Named from μονάζω, *to be solitary*, in allusion to its rare occurrence.

Monazitoid Hermann (J. pr. Ch., xl. 21). This mineral is monazite in crystallization and external characters. H.=5. G.=5·281. Hermann states that the brown color is distinct Hermann obtained in his analysis:

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$ 17·94 $\dot{\text{C}}\text{e}$ 49·35 $\dot{\text{L}}\text{a}$ 21·80 $\dot{\text{C}}\text{a}$ 1·50 $\dot{\text{H}}$ 1·36, subst. like tantalum 6·27, $\dot{\text{M}}\text{g}$, $\dot{\text{F}}\text{e}$ *tr.*=97·72

B.B. infusible. With the fluxes like monazite.

497. TURNERITE *Levy*, Ann. Phil., xviii. 241, 1823. Turnerite is isomorphous with monazite

---

* Am. J. Sci., xxxiii, 70, 1838. Fig. 8 in that article is zircon, and not monazite.

and like it in cleavage and color, and may be the same species. It is known only n rare crystals; the original, from Mt Sorel in Dauphiny (measured by Levy, Marignac, Phillips, and Des-cloizeaux); later, from Santa Brigritta, near Ruäras in the Tavetsch valley, Alps (measured by vom Rath). The accompanying profile figure is from vom Rath (Pogg., cxix. 247), but reversed in position so as to make it correspond with the above; moreover, the plane of perfect cleavage is made the basal, as in monazite, instead of i-ì, that so made by v. Rath. Some of the angles are as follows: those unaccredited, v. Rath's calculated results, from 1-ì ∧ 1=141° 28', 1-ì ∧ 1=143° 44', i-ì ∧ 1-ì=131° 58'; those with Dx. affixed, Des-cloizeaux's ditto, from i-ì ∧ 1-ì=100, i-ì ∧ 1-ì=126° 31', 1-ì ∧ 1-ì=96° 20'; those with M., P., L., affixed, measurements by, respectively, Marignac, Phillips, Levy:

Turnerite is described as having H. above 4; lustre adamantine; color yellow or brown; streak white or grayish; transparent to translucent. Children, after some imperfect trials, made out that it contained alumina, lime, magnesia, a little iron, with no titanic acid, and very little silica. At Mt. Sorel it occurs with quartz, albite, orthoclase, crichtonite, and octahedrite; and in the Tavetsch valley, with quartz crystal and octahedrite in talcose schist.

498 TRIPHYLITE. Triphylin *Fuchs*, J. pr. Ch., iii. 98, 1834, v. 319, 1835. Tetraphylin *Berz.*, Arsb., xv. 1835. Perowskyn *N. Nordenskiöld.*

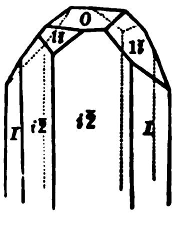
Norwich.

451



Bodenmais.

Faces of crystals usually uneven. Cleavage: *O* nearly perfect in unaltered crystals. Massive.

H.=5. G.=3·54--3·6; 3·545—3·561, Bodenmais, Oesten. Subresinous. Color greenish-gray; also bluish; often brownish-black externally Streak grayish-white. Translucent in thin fragments.

Comp.—$(\dot{\mathrm{F}}\mathrm{e}, \dot{\mathrm{M}}\mathrm{n}, \dot{\mathrm{L}}\mathrm{i})^3\overset{...}{\mathrm{P}}$, Fuchs. Oesten's analysis, which was made on the pure minera wholly unaltered, sustains Fuchs's formula. O. ratio for $\dot{\mathrm{F}}\mathrm{e}+\dot{\mathrm{M}}\mathrm{n}$, $\dot{\mathrm{L}}\mathrm{i}+\dot{\mathrm{N}}\mathrm{a}+\dot{\mathrm{M}}\mathrm{g}=2:1$.

Analyses: 1, Fuchs (J. pr. Ch., iii. 98, v. 319); 2, 3, Rammelsberg (Pogg., lxxxv. 439); 4, Baer (Arch. Pharm., II. lvii. 374); 5, G. O. Wittstein (Viert. pr. Pharm., i. 506); 6. Gerlach (ZS nat. Ver. Halle, lx 149); 7, Oesten (Pogg., cvii. 438); 8, imperfect anal. by Berzelius and N Nordenskiöld (Jahresb., xv. 211):

The excess in the analysis of the Finland mineral (tetraphyline) is supposed to be owing to an incorrect determination of the lithia.

Pyr., etc.—In the closed tube sometimes decrepitates, turns to a dark color, and gives off traces of water. B.B. fuses at 1·5, coloring the flame beautiful lithia-red in streaks, with a pale bluish-green on the exterior of the cone of flame. The coloration of the flame is best seen when the pulverized mineral moistened with sulphuric acid is treated on a loop of platinum wire. With borax gives an iron bead; with soda a reaction for manganese. Soluble in muriatic acid.

Obs.—Triphylite occurs at Rabenstein, near Zwiesel, in Bavaria; and f. 451 is from a large somewhat distorted Bavarian crystal in the cabinet of R. P. Greg, Jr., having the appearance of being altered; also at Keityö, in Finland (perowskine or tetraphyline); Norwich, Mass.

On cryst., Tschermak, Ber. Ak. Wien, xlvii. 282; R. P. Greg, this Min., 406, 1854; Dana, ib. Named from *τρίς*, *three-fold*, and *φυλή*, *family*, in allusion to its containing three phosphates.

Alt.—Triphylite and triplite, like other minerals containing protoxyd of manganese, undergo easy alteration by oxydation and hydration; and the former also by losing its alkalies. The sesquioxyd of iron in Wittstein's analysis (anal. 5) is thus accounted for. The following have come from the alteration of one or the other of these minerals.

A. HETEROSITE. Heteposite *Alluaud*, in an Art. by *Vauquelin*, Ann. Ch. Phys., xxx. 294, 1825. Heterosite, Heterozite, *Alluaud*, Ann. Sci. Nat., viii. 346, 1826.

Cleavable massive and lamellar; cleavage stated to be in three directions, unequal, affording an oblique prism of 100°-101°. H.=5·5–6; G.=3·52, or 3·39 after further alteration, Dufrénoy; lustre resinous, or like that of apatite; color greenish- and bluish-gray, becoming violet and submetallic on exposure. Soluble in acids, with a slight residue of silica. B.B. fuses to a deep brown submetallic enamel. Found in pegmatyte near Limoges, Dept. of Haute Vienne, France, and especially at the quarries of Hureaux. Named *heterosite* from *ἕτερος*, *other* or *different*, but misspelt by Vauquelin.

B. PSEUDOTRIPLITE *Blum*, Orykt., 2 Aufl., 537, with anal. by Delffs. Resembles triplite; but occurs incrusting triphylite at Rabenstein, Bavaria, to the alteration of which its formation is owing.

C. ALLUAUDITE *Damour*, Ann. d. M., IV. xiii. 341, 1848 [not Alluaudite *Bernhardi*]. In nodules, or massive, with three rectangular cleavages as in triplite, two rather easy, the other less so. H.=4–5; G.=3·468, Damour. Color brown, brownish-red at the edges by transmitted light; powder brownish-yellow. B.B. fuses easily to a black magnetic globule. Dissolves in muriatic acid with evolution of chlorine. Supposed to be altered triplite, and comes from Chanteloube, near Limoges.

D *Altered Triphylite from Norwich, Mass.* The Norwich mineral is found only in crystals, some an inch long and wide, associated with spodumene in quartz. The crystals vary much in their angles; the faces are smooth but hardly polished. The following angles were obtained by the author from 8 crystals (the right-hand *i*-2 is here accented):

	I.	II.	III.	IV.	V.	VI.	VII.	VIII.
i-2 ∧ *i*-2′	128°	131°–132°	127°–130½°	130½	126°	134°	128°	130°
i-2 ∧ *i*-ĭ			118	118		108	108	
i-2 ∧ *i*-ī		121½–122				120	115	118–119
O ∧ 1-ĭ		131	129–132					
i-2 ∧ 1-ĭ		101½–102						

	I.	II.	III.	IV.	V.	VI.	VII.	VIII.
i-$\bar{2}$ ∧ 1-$\bar{i}$		118½°	110°	110°–112°				
i-$\bar{2}$ (or i-$\bar{2}'$) ∧ I	159°	162						
O ∧ obtuse edge of I		94–97 86–87	 86	90	 86°	93°	100° 80	90° 90
I ∧ I			93					

Many of the crystals have a monoclinic form, while others are orthorhombic; but the latter is the normal form; the obliquity having resulted from some movement in the enclosing rock after the crystals were made. They closely resemble in form the crystals from Bavaria. Cleavage not distinct. Color black; streak brownish-red; opaque; brittle; H.=5·5; G.=2·876, Craw. In composition, quite near alluaudite, as observed by Mallet. Brush found the interior of a crystal true triphylite, with color grayish-green; H.=5, and G.=3·534 (Am. J. Sci., II. xxxiv. 402).

Analyses: 1, Dufrénoy (Ann. Ch. Phys., xli. 342); 2, Rammelsberg (Pogg., lxxxv. 439); 3, Fuchs (J. pr. Ch., iii. 98, v. 319); 4, Delffs (l. c.); 5, Damour (l. c.); 6, 7, W. J. Craw (Am. J. Sci., II. xi. 99); 8, J. W. Mallet (ib., xviii. 88):

	$\overset{\cdots}{\mathrm{P}}$	$\bar{\mathrm{F}}\mathrm{e}$	$\bar{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{L}}\mathrm{i}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{S}}\mathrm{i}$

8. " "	(⅓) 43·04	29·50	22·59	——	——	0·09	1·79	2·05	——, $\dot{\mathrm{M}}\mathrm{g}$ 0·73=99·79 M.

Heterosite, by Rammelsberg's analysis, gives the O. ratio for bases, acid, and water 18·67 : 18·13 : 5·64, and was made on a brownish-violet specimen having G.=3·41; by Dufrénoy's, 8 : 6 : 1. *Pseudotriplite* corresponds nearly to 9 : 10 : 2. *Alluaudite* gives approximately, supposing the manganese to be protoxyd, as stated in the analysis, for the O. ratio for $\dot{\mathrm{R}}$, $\bar{\mathrm{R}}$, $\overset{\cdots}{\mathrm{P}}$, $\dot{\mathrm{H}}$= 5 : 6 : 18 : 2; and the Norwich mineral 1 : 9 : 15 : 1. It is useless to write formulas for these compounds until the state of oxydation of the iron and manganese has been more precisely ascertained; and even then they are of little value, as the mineral in the altered state is probably a mere mixture.

MELANCHLOR *Fuchs* (J. pr. Ch., xvii. 171) is altered triphylite according to Sæmann (this Min., 4th ed., 518) It is a phosphate of iron from Rabenstein, containing, in 100 parts, 38·9 sesquioxyd and 3·87 protoxyd of iron, besides protoxyd of manganese, and 9 to 10 p. c. of water; it occurs on triphylite. The name alludes to its blackish-green color.

499. TRIPLITE. Phosphate natif de fer melangé de manganèse (fr. Limoges) *Vauq.*, J. de M., xi. 295, 1802, Ann. Ch., xli. 242, 1802. Eisenpecherz pt. *Wern.*, 1808. Orthorhombic. Imperfectly crystalline. Cleavage: unequal in three directions perpendicular to each other, one much the most distinct.

H.=4–5·5. G.=3·44–3·8; 3·617, fr. Peilau, Berg. Lustre resinous, inclining to adamantine. Color brown or blackish-brown to almost black. Streak yellowish-gray or brown. Subtranslucent—opaque. Fracture small conchoidal.

Comp.—$\dot{\mathrm{R}}^3\overset{\cdots}{\mathrm{P}}+\mathrm{R\,F}$, v. Kobell, with $\dot{\mathrm{R}}$ in anal. 3 =⅓ $\dot{\mathrm{F}}\mathrm{e}$ + ⅔ $\dot{\mathrm{M}}\mathrm{n}$, and R=1 Ca + 2 Mg + 3 Fe, which gives for the percentage composition, Phosphoric acid 32·7, protox. iron 16·6, protox. manganese 32·2, iron 6·4, magnesium 1·8, calcium 1·5, fluorine 8·8=100. Analyses: 1, Berzelius (Schw. J., xxvii. 70); 2, Bergemann (J. pr. Ch., lxxix. 414); 3, v. Kobell (J. pr. Ch., xcii. 390); 4, Fuchs (J. pr. Ch., xviii. 499); 5, Rammelsberg (4th Suppl., 247):

[a] Phosphate of lime.

[b] With some Li O.

Von Kobell's analysis becomes, on combining the fluorine with Fe, Ca, Mg, P̈ 33·85, Ḟe 19·86, Ṁn 30·00, Fe 5·54, Mg 1·83, Ca 1·57, F 8·10=100·75.

Pyr., etc.—B.B. fuses easily at 1·5 to a black magnetic globule; moistened with sulphuric acid colors the flame bluish-green. With borax in O.F. gives an amethystine colored glass (manganese); in R F. a strong reaction for iron. With soda reacts for manganese. With sulphuric acid evolves fluohydric acid. Soluble in muriatic acid.

Obs.—Found by Alluaud at Limoges in France, in a vein of quartz in granite, accompanied by apatite; occurs also at Peilau in Silesia.

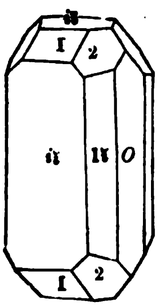
Zwieselite, a clove-brown variety, was found by Fuchs near Rabenstein, 1 league from Zwiesel, in Bavaria, in quartz (G.=3·97 Fuchs). Fuchs in his Mineralogy suggests its relation to triplite. It is stated to have a rather perfect basal cleavage; a brachydiagonal little distinct; and a prismatic parallel to a prism of 129° very imperfect.

Alt.—Often occurs coated with oxyd of manganese as a result of its alteration.

500. HOPEITE. *Brewster*, Trans. R. Soc. Edinb., x. 107, 1825. Prismatoidischer Zinkphyllit *Breith.*, Char., 38, 1832.

Orthorhombic. *I* ∧ *I*=101°, *O* ∧ 1-ĭ=133° 19′, Levy; *a* : *b* : *c*=1·0607 : 1 : 1·2131. Observed planes as in the annexed figure, with also 2-ĭ, 3-ĭ, and *i*-ī.

452



O ∧ 1-ĭ=138° 50′
1-ĭ ∧ 1-ĭ, ov. *O*,=97 40
O ∧ 2-ĭ=119 47

2 ∧ 2, brach.,=87° 3′
2 ∧ 2, macr.,=106 36
2 ∧ 2, bas.,=140

Cleavage: *i*-ĭ highly perfect. Plane *O* striated. Also in reniform masses, and amorphous.

H.=2·5—3. G.=2·76—2·85. Lustre vitreous; *i*-ĭ somewhat pearly. Color grayish-white; reddish-brown when compact. Streak white. Transparent—translucent.

Pyr., etc.—Dissolves without effervescence in muriatic or nitric acid, and is slowly affected by sulphuric acid. B.B. gives out water, and then melts with difficulty to a clear colorless globule, tinging the flame green. The globule obtained with borax remains clear on cooling. With soda it affords a scoria which is yellow when hot, and gives out copious fumes of zinc and some of cadmium. The fused mineral forms a fine blue glass with a solution of cobalt. Hopeite is supposed, therefore, to be a hydrous compound of phosphoric acid and oxyd of zinc, with a small portion of cadmium. N. Nordenskiöld, Jahresb., v. 198, 1825.

Obs.—Found in the calamine mines of Altenberg, near Aix la Chapelle.

Named in honor of Prof. Hope of Edinburgh.

The angle of ½-ĭ ∧ ½-ĭ in hopeite is near *i*-2̄ ∧ *i*-2̄ in fischerite.

501. BERZELIITE. Berzeliit *Kühn*, Ann. Ch. Pharm., xxxiv. 211, 1840. Magnesian Pharmacolite *Dana*, Min., 239, 1844. Chaux arseniatée anhydre *Dufr.* Berzelit *Haid.*, Handb., 495, 1845. Kühnite *B. & M.*, Min., 481, 1852.

Massive, with cleavage in one direction.

H.=5—6. G.=2·52. Lustre waxy. Color dirty-white or honey-yellow. Brittle.

Comp.—$(\dot{\mathrm{C}}\mathrm{a}, \dot{\mathrm{M}}\mathrm{g}, \dot{\mathrm{M}}\mathrm{n})^{10}\, \ddot{\bar{\mathrm{A}}}\mathrm{s}^{3}$. O. ratio for $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{A}}}\mathrm{s}$=1 : 1½. Analyses: Kühn (l. c.):

	$\ddot{\bar{\mathrm{A}}}\mathrm{s}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{M}}\mathrm{n}$	ign.
1.	58·51	23·22	15·68	2·13	0·30=99·84 Kühn.
2.	56·46	20·96	15·61	4·26	2·95, insol. 0·23=100·47 Kühn.

Another partial analysis gave $\dot{\mathrm{C}}\mathrm{a}$ 21·31, $\dot{\mathrm{M}}\mathrm{g}$, $\dot{\mathrm{M}}\mathrm{n}$ 17·07.

Pyr., etc.—B.B. infusible, but turns gray. With soda on charcoal gives an arsenical odor, with soda on platinum foil fuses with effervescence, and gives a manganese reaction. Soluble in nitric acid.

Obs.—Occurs at Longban in Sweden, with iron ore and granular dolomite.

502. CARMINITE. Carminspath *Sandberger*, Pogg., lxxx. 391, 1859. Carmine Spar. Carminite *Dana*, Min., 410, 1854.

Orthorhombic. In clusters of fine needles. Also in spheroidal forms with a columnar structure. Cleavage parallel to the faces of a rhombic prism.

H.=2·5. G.=4·105. Lustre vitreous, but cleavage pearly. Color carmine to tile-red; powder reddish-yellow. Translucent. Brittle.

Comp.—O. ratio for $\dot{\mathrm{P}}\mathrm{b}$, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$, $\ddot{\bar{\mathrm{A}}}\mathrm{s}$=1½ : 9 : 17; or for bases and acid 2 : 3, or, less nearly, 3 : 5. Sandberger and Muller adopt the latter, and write the formula $\dot{\mathrm{P}}\mathrm{b}^{3}\,\ddot{\bar{\mathrm{A}}}\mathrm{s}+5\,\dddot{\bar{\mathrm{F}}}\mathrm{e}\,\ddot{\bar{\mathrm{A}}}\mathrm{s}$. Analysis by R. Müller (Pogg., ciii. 345):

$\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 49·11 $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 30·29 $\dot{\mathrm{P}}\mathrm{b}$ 24·55=103·95.

Pyr., etc.—B.B. on charcoal fuses easily to a steel-gray globule, giving out arsenical vapors; with soda a globule of lead, and with borax an iron reaction. Heated in a glass tube no change Soluble in nitric acid.

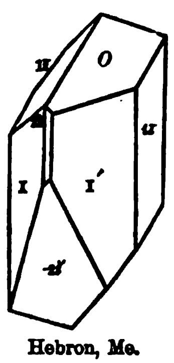
Obs.—From Horhausen in Prussia, 12–16 m. N.E. of the town of Neuwied on the Rhine, with beudantite and quartz in a mine of limonite.

503. AMBLYGONITE. Amblygonit *Breith.*, Hoffm. Min., iv. b, 159, 1817, Handb., 483.

Triclinic. Observed planes as in the annexed figure, Dana.

$I \wedge I$=73° 20′	$I \wedge i\text{-}\bar{i}$=135° 30′
$O \wedge i\text{-}\bar{i}$=105	$I \wedge i\text{-}\breve{2}$=155 30
$O \wedge I$, back,=87 40	$I' \wedge i\text{-}\breve{2}$=97 50
$O \wedge I'$=111 30 ?	$I \wedge 2\text{-}\breve{i}$=107 30
$O \wedge$ edge I/I=78 30 ?	$i\text{-}\bar{i} \wedge 2\text{-}\breve{i}$, ov. I,=142 30
$O \wedge 2\text{-}\breve{i}$=105 20	$i\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, adj.,=131 50

453



Hebron, Me.

Cleavage: O perfect; $i\text{-}\bar{i}$ nearly perfect, angle between these cleavages 104½°; also I imperfect. Usually massive, cleavable; sometimes columnar.

H.=6. G.=3–3·11; 3·046, Hebron, Brush. Lustre pearly on face of perfect cleavage (O); vitreous on $i\text{-}\bar{i}$, less perfect cleavage-face; on cross-fracture a little greasy. Color pale mountain or sea-green, white, grayish, brownish-white. Subtransparent—translucent. Fracture uneven. Optical axes very divergent; plane of axes nearly at right angles to $i\text{-}\bar{i}$; bisectrix of the acute angle negative, and parallel to the edge $O/i\text{-}\bar{i}$; Descl.

Comp.—Perhaps $(\frac{1}{2}(\mathrm{Li}, \dot{\mathrm{N}}\mathrm{a})^{3}+\frac{1}{2}\,\dddot{\bar{\mathrm{A}}}\mathrm{l})^{4}\,\ddot{\bar{\mathrm{P}}}$, with *one-ninth* of the oxygen replaced by fluorine Analyses: 1, Berzelius (Gilb. Ann., lxv. 321); 2, Rammelsberg (Pogg., lxiv. 265, Min. Ch., 359)

	$\ddot{\text{P}}$	$\overline{\overline{\text{Al}}}$	$\dot{\text{L}}$i	$\dot{\text{N}}$a	$\dot{\text{K}}$	F	
1. Chursdorf	56·69	35·69	9·11	——	——	——	Berz.
2. Arnsdorf; G.=3·11 (½)	47·58	36·88	6·68	3·29	0·43	8·11=102·97	Ramm.

In three trials the alumina was found to be 36·26, 36·62, and 36·89 p. c. Rammelsberg deduces the formula $(\overline{\overline{\text{Al}}}^5\ddot{\text{P}}^3+\dot{\text{R}}^5\ddot{\text{P}}^3)+(\text{Al}^2\text{F}^3+\text{R F})$, R standing for lithium and sodium; Rose writes $(2\dot{\text{R}}^2\ddot{\text{P}}+2\overline{\overline{\text{Al}}}\ddot{\text{P}})+(\text{Al}^2\text{F}^3+\text{Al}^2\text{O}^3)$.

Pyr., etc.—In the closed tube yields water, which at a high heat is acid and corrodes the glass. B.B. fuses easily (at 2) with intumescence, and becomes opaque white on cooling. Colors the flame yellowish-red with traces of green; the Hebron variety gives an intense lithia-red; moistened with sulphuric acid gives a bluish-green to the flame. With cobalt solution assumes a deep blue color (alumina). With borax and salt of phosphorus forms a transparent colorless glass. In fine powder dissolves easily in sulphuric acid, more slowly in muriatic.

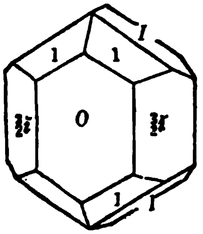
Obs.—Occurs at Chursdorf and Arnsdorf, near Penig in Saxony, where it is associated with tourmaline and garnet in granite; also at Arendal, Norway. In the U. States, in Maine, at Hebron, imbedded in a coarse granite in masses, sometimes well crystallized, with lepidolite, albite, quartz, red, green, and black tourmaline, apatite, and rarely cassiterite; also at Mt. Mica in Paris, 8 m. from Hebron, with tourmaline. The Hebron crystals have rather rough faces, admitting only of approximative measurement, and are occasionally 1 in. thick and 2 in. long (Am. J. Sci., II. xxxiv. 243). The angles above are from measurements by the author of Hebron crystals. Descloizeaux obtained from the cleavages of the Hebron mineral *O* (*p*) ∧ *i*-ī (*m*)=105°; *O* (*p*) ∧ *I* (*t*)=88° 30′, *I* (*t*) ∧ *i*-ī (*m*)=135° (C. R., lvii. 357, Pogg., cxxiii. 188).

The name is from ἀμβλύς, *blunt*, and γόνυ, *angle*.

504. HERDERITE. Herderite *Haid.*, Phil. Mag., iv. 1, 1828. Allogonit *Breith.*, Ulb., 23, 1830, Char., 78, 1832.

Orthorhombic. *I* ∧ *I*=115° 53′, *O* ∧ 1-ī=145° 51′; *a* : *b* : *c*=0·6783 : 1 : 1·5971. Observed planes as in the annexed figure, with also 3, 4, and 6-ĭ.

454



O ∧ 1=141° 19′
O ∧ 3=112 35
O ∧ $\frac{3}{2}$-ĭ=147 30
1 ∧ 1, mac.,=141° 17′
1 ∧ 1, brach.,=116 3
O ∧ *I*=90

Cleavage: *I* interrupted. Surfaces *I* and 1 very smooth, and delicately lined parallel to their edge of intersection.

H.=5. G.=2·985. Lustre vitreous, inclining to subresinous. Streak white. Color various shades of yellowish- and greenish-white. Translucent. Fracture small conchoidal. Very brittle. Index of refraction 1·47.

Comp.—Probably, according to trials by Turner and Plattner, an anhydrous phosphate of alumina and lime with fluorine.

Pyr., etc.—B.B. fuses with difficulty to a white enamel; becomes blue with cobalt solution. Dissolves when finely powdered in muriatic acid.

Obs.—Very rare at the tin mines of Ehrenfriedersdorf in Saxony. Resembles the asparagus variety of apatite.

Named after Baron von Herder, director of the Saxon mines.

---

505. MONIMOLITE. Monimolit *L. J. Igelström*, Œfv. Ak. Stockh., 1865, 227.

Tetragonal. In octahedrons. Also massive and incrusting.

H.=4·5—5. G.=5·94. Lustre submetallic, greasy. Color yellow Powder citron-yellow. Fracture granular.

Comp.—($\dot{\text{Pb}}$, $\dot{\text{Fe}}$, $\dot{\text{Mn}}$, $\dot{\text{Ca}}$, $\dot{\text{Mg}}$)^4 $\ddot{\ddot{\text{Sb}}}$, but mainly antimonate of lead. **Analysis:** Igelström (l. c.)

$\ddot{\ddot{\text{Sb}}}$ 40·29 $\dot{\text{Pb}}$ 42·40 $\dot{\text{Fe}}$ $\dot{\text{Mn}}$ 6·20 $\dot{\text{Ca}}$ 7·59 $\dot{\text{Mg}}$ 3 25=99·73.

Pyr., etc.—B.B. on charcoal gives a malleable lead-colored globule, which in O.F. gives a white coating of antimony, and nearer the assay the yellow of oxyd of lead. Insoluble in strong acids, or with carbonated or caustic alkalies, even on fusion. Reduced by hydrogen gas at a red heat; becomes soluble in acids.

Obs.—Occurs with tephroite at the manganese mine of Pajsberg, in Wermland, Sweden.

506. ROMEITE. Romeine *Damour*, Ann. d. M., III. xx. 247, 1841; V. iii. 179, 1853

Tetragonal. In octahedrons, near the regular octahedron in form; 1 ∧ 1, basal, 110° 50′—111° 20′; over the summit, 68° 10′—69° 10′. Occurs in groups of minute crystals. Cleavage none.

H. above 5·5. G. in grains, 4·714; in powder, 4·675. Color hyacinth or honey-yellow.

Comp.—$\dot{\text{R}}^3$, SbO^3, SbO^5 Damour=Antimony 62·24, oxygen 16·32, lime 21·44=100. **Analysis** by Damour (l. c., 1853):

O 15·82 Sb 62·18 Fe 1·31 $\dot{\text{Mn}}$ 1·21 $\dot{\text{Ca}}$ 16·29 $\dddot{\text{Si}}$ sol. 0·96 insol. 1·90=99·67.
or Sb O^5 40·79 Sb O^3 36·82 $\dot{\text{Fe}}$ 1·70 1·21 16·29 0·96 1·90=99·67.

In his earlier analysis (1841) Damour obtained Sb O^3 79·31, $\dot{\text{Fe}}$ 1·20, $\dot{\text{Mn}}$ 2·16, $\dot{\text{Ca}}$ 16·67, $\dddot{\text{Si}}$ sol 0·64=99·98.

Pyr., etc.—B.B. fuses to a blackish slag. With borax affords a colorless glass in the inner flame, a violet in the outer (manganese). With soda on charcoal gives white antimonial fumes and globules of metallic antimony; fused on platinum foil with soda gives a bluish-green manganate. Insoluble in acids.

Obs.—Romeite was found by B. de Lom at St. Marcel in Piedmont, in small nests or veins in the gangue which accompanies manganese, consisting in part of feldspar, epidote, quartz, limonite, and greenovite.

Named by Damour (*not* by Dufrénoy) after the crystallographer Romé de l'Isle.

507. AMMIOLITE. Antimonite de Mercure *Domeyko*, Ann. d. M., IV. vi. 183, 1844. Cinabrio subido *Domeyko*, Min., 168, 1845. Ammiolite *Dana*, Min., 534, 1850. Antimoniato de cobre con cinabrio terroso *Domeyko*, Min., 129, 1860.

Earthy powder. Color deep red, scarlet.

Comp.—Results variable; but regarded as antimonate of copper mixed with cinnabar and with other impurities. Analyses by Domeyko (Min., 129, 1860) of the material obtained in the earliest part of a process of levigation:

$\ddot{\ddot{\text{Sb}}}$	$\dot{\text{Cu}}$	Hg	S	$\ddot{\text{Fe}}$	quartz	$\dot{\text{H}}$ and loss.
24·1	16·9	19·9	3·3	2·2	24·8	8·8
29·5	15·6	23·6	3·3	3·1	8·1	16·9
28·1	18·1	19·8	3·1	1·1		

Rivot has found in a similar substance from Chili (Ann. d. M., V. vi. 556), Sb 36·5, Cu 12·2, Hg 22·2, Te 14·8, Fe, S *tr.*, quartz 2·5, O and loss 12·6, and observes that his result indicates the presence of tellurid of mercury and antimonic acid along with antimonate of copper.

Pyr., etc.—Effervesces with nitric acid, without loss of color; but loss of color by action of muriatic acid, and an abundant deposit of white antimonic acid. Heated in a matrass, a sublimate of mercury.

Obs.—Found in many of the Chilian mines, filling cavities in the quartzose or argillo-ferruginous gangue of the mercurial tetrahedrite, and in the pores of the imperfectly compact tetrahedrite itself, and has proceeded from the decomposition of this mercurial ore.

Named from *ἄμμιον*, *vermilion*.

F. Field has analyzed a red earthy substance from Tambillos, near Coquimbo, Chili, and made it a compound of antimonite of mercury and sulphantimonite of mercury; but there is much uncertainty over his results. He obtained (Q. J. Ch. Soc., xii. 27,

Sb	S	Hg	$\ddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{H}}$	quartz
14·21	5·43	34·42	2·68	4·46	35·50=96·70.
15·26	5·98	37·94	2·94	4·98	29·78=96·88.

He takes the loss as partly oxygen, and thus makes $\mathrm{Sb\,O^3}$, $\mathrm{Sb\,S^3}$, Hg O, Hg S as the constituents. The material is probably a mixture of cinnabar, etc.

APPENDIX.

508. **Arsenate of Nickel** (Nickelerz, $\dot{\mathrm{Ni}}^3\ddot{\bar{\mathrm{A}}}\mathrm{s}$, *C. Bergemann*, J. pr. Ch., lxxv. 239, 1858). Crystalline massive or amorphous. H.=4. G.=4·838. Color dark grass-green to brownish in spots where amorphous; streak lighter.

Formula given by Bergemann (l. c.) $\dot{\mathrm{Ni}}^3\ddot{\bar{\mathrm{A}}}\mathrm{s}$=Arsenic acid 38·0, oxyd of nickel 62·0=100. His analysis afforded:

$\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 36·57 $\ddot{\bar{\mathrm{P}}}$ 0·14 $\dot{\mathrm{Ni}}$ 62·07 $\dot{\mathrm{Co}}$ 0·54 $\dot{\mathrm{Cu}}$ 0·34 $\ddot{\bar{\mathrm{B}}}\mathrm{i}$ 0·24 $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ *tr.*=99·90.

Unaltered in the closed tube. B.B. on charcoal affords arsenical fumes; with borax in R.F. gives a gray bead (nickel); with soda on charcoal gives off arsenical fumes and yields a magnetic mass. From Johanngeorgenstadt, along with the following, nickel oxyd, and native bismuth.

509. **Arsenate of Nickel** (Nickelerz, $\dot{\mathrm{Ni}}^3\ddot{\bar{\mathrm{A}}}\mathrm{s}$, *C. Bergemann*, J. pr. Ch., lxxv. 239, 1858). Amorphous. H.=4. G.=4·982. Color sulphur-yellow. Formula $\dot{\mathrm{Ni}}^3\ddot{\bar{\mathrm{A}}}\mathrm{s}$, Bergemann,=Arsenic acid 50·5, $\dot{\mathrm{Ni}}$ 49·5=100. Analysis by Bergemann (l. c.):

$\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 50·53 $\ddot{\bar{\mathrm{P}}}$ *tr.* $\dot{\mathrm{Ni}}$ 48·24 $\dot{\mathrm{Co}}$ 0·21 $\dot{\mathrm{Cu}}$ 0·57 $\ddot{\bar{\mathrm{B}}}\mathrm{i}$ 0·62=100·17.

Like the preceding in pyrognostic characters. Occurs at Johanngeorgenstadt, with the preceding.

II. HYDROUS PHOSPHATES, ARSENATES, ANTIMONATES.

ARRANGEMENT OF THE SPECIES.

A. Phosphates and Arsenates of Bases in the Protoxyd state.

I. STRUVITE GROUP. Contain ammonia. O. ratio for bases and acid 3 : 5.

515. **Stercorite** $(\frac{1}{3}\dot{\mathrm{N}}\mathrm{a}+\frac{1}{3}\mathrm{NH^4O}+\frac{1}{3}\dot{\mathrm{H}})^3\ddot{\bar{\mathrm{P}}}+8\dot{\mathrm{H}}$ $\mathrm{P\Theta|\Theta_3|(\frac{1}{3}Na+\frac{1}{3}Am+\frac{1}{3}H)_3+4\,aq}$

516. **Struvite** $(\frac{2}{3}\dot{\mathrm{M}}\mathrm{g}+\frac{1}{3}\mathrm{NH^4O})^3\ddot{\bar{\mathrm{P}}}+12\dot{\mathrm{H}}$ $\mathrm{(P\Theta)_2|\Theta_6|(\frac{1}{3}Am_2+\frac{2}{3}Mg)_3+12\,aq}$

II. HAIDINGERITE GROUP. Contain lime. O. ratio 3 : 5. Orthorhombic, with a pearly diagonal cleavage.

517 **Haidingerite** $(\frac{2}{3}\dot{\mathrm{C}}\mathrm{a}+\frac{1}{3}\dot{\mathrm{H}})^3\ddot{\bar{\mathrm{A}}}\mathrm{s}+3\dot{\mathrm{H}}$ $\mathrm{(As\Theta)_2|\Theta_6|(\frac{2}{3}\Theta a+\frac{1}{3}H_2)_3+3\,aq}$

III. PHARMACOLITE GROUP. Contain lime or magnesia. O. ratio 3 : 5. Monoclinic, with a pearly clinodiagonal cleavage.

518. **Brushite**	$(\frac{2}{3}\dot{\text{Ca}}+\frac{1}{3}\dot{\text{H}})^3\ddot{\bar{\text{P}}}+4\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert(\frac{2}{3}\Theta\text{a}+\frac{1}{3}\text{H}_2)_3+4\text{ aq}$
519. **Metabrushite**	$(\frac{2}{3}\dot{\text{Ca}}+\frac{1}{3}\dot{\text{H}})^3\ddot{\bar{\text{P}}}+3\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert(\frac{2}{3}\Theta\text{a}+\frac{1}{3}\text{H}_2)_3+3\text{ aq}$
520. **Pharmacolite**	$(\frac{2}{3}\dot{\text{Ca}}+\frac{1}{3}\dot{\text{H}})^3\ddot{\bar{\text{As}}}+5\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert(\frac{2}{3}\Theta\text{a}+\frac{1}{3}\text{H}_2)_3+5\text{ aq}$
521. **Churchite**	$(\dot{\text{Ca}},\dot{\text{Ce}})^3\ddot{\bar{\text{P}}}+4\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert(\Theta\text{a},\Theta\text{e})_3+4\text{ aq}$
522. **Hœrnesite**	$\dot{\text{Mg}}^3\ddot{\bar{\text{As}}}+8\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert\text{Mg}_3+8\text{ aq}$
523. **Rœsslerite**	$(\frac{2}{3}\dot{\text{Mg}}+\frac{1}{3}\dot{\text{H}})^3\ddot{\bar{\text{As}}}+12\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert(\frac{2}{3}\text{Mg}+\frac{1}{3}\text{H}_2)_3+12\text{ aq}$

IV. VIVIANITE GROUP. Contain iron, manganese, nickel, cobalt, or zinc. O. ratio 3 : 5 Monoclinic, with a pearly clinodiagonal cleavage.

524. **Vivianite**	$\dot{\text{Fe}}^3\ddot{\bar{\text{P}}}+8\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert\text{Fe}_3+8\text{ aq}$
525. **Symplesite**	$\dot{\text{Fe}}^3\ddot{\bar{\text{As}}}+n\text{ aq}$	$(\text{As}\Theta)_2\vert\Theta_6\vert\text{Fe}_3+n\text{ aq}$
526. **Erythrite**	$\dot{\text{Co}}^3\ddot{\bar{\text{As}}}+8\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert\Theta\text{o}_3+8\text{ aq}$
527. **Annabergite**	$\dot{\text{Ni}}^3\ddot{\bar{\text{As}}}+8\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert\text{Ni}_3+8\text{ aq}$
529. **Cabrerite**	$(\dot{\text{Ni}},\dot{\text{Co}},\dot{\text{Mg}})^3\ddot{\bar{\text{As}}}+8\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert(\text{Ni},\Theta\text{o},\text{Mg})_3+8\text{ aq}$
530. **Köttigite**	$(\dot{\text{Zn}},\dot{\text{Co}},\dot{\text{Ni}})^3\ddot{\bar{\text{As}}}+8\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert(\text{Zn},\Theta\text{o},\text{Ni})_3+8\text{ aq}$
531. **Hureaulite**	$(\dot{\text{Mn}},\dot{\text{Fe}},\dot{\text{H}})^3\ddot{\bar{\text{P}}}+2\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert(\text{Mn},\text{Fe},\text{H}_2)_3+2\text{ aq}$

V. CHONDRARSENITE GROUP. Contain manganese. O. ratio 1 : 1? No cleavage observed.

532. **Chondrarsenite**	$\dot{\text{Mn}}^5\ddot{\bar{\text{As}}}+2\frac{1}{2}\dot{\text{H}}$	$\text{As}_2\vert\Theta_{10}\vert\text{Mn}_5+2\frac{1}{2}\text{ aq}$

VI. OLIVENITE GROUP. Contain $\dot{\text{Cu}}$, $\dot{\text{Zn}}$ as the protoxyd bases. General formula $\dot{\text{R}}^3(\ddot{\bar{\text{P}}},\ddot{\bar{\text{As}}})+n$ aq, with sometimes $\dot{\text{Cu}}\dot{\text{H}}$, or $\dot{\text{Zn}}\dot{\text{H}}$, accessory. Orthorhombic, without pearly cleavage; *I* ∧ *I* near 90°.

533. **Trichalcite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+5\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert\Theta\text{u}_3+5\text{ aq}$
534. ? **Thrombolite**	$\ddot{\bar{\text{P}}},\text{Cu},\dot{\text{H}}$	
535. **Libethenite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{P}}}+\dot{\text{Cu}}\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert\Theta\text{u}_3+\Theta\text{u}\,\text{H}_2\Theta_2$
536. **Olivenite**	$\dot{\text{Cu}}^3(\ddot{\bar{\text{As}}},\ddot{\bar{\text{P}}})+\dot{\text{Cu}}\dot{\text{H}}$	$((\text{As},\text{P})\Theta)_2\vert\Theta_6\vert\Theta\text{u}_3+\Theta\text{u}\,\text{H}_2\Theta_2$
537. **Adamite**	$\dot{\text{Zn}}^3\ddot{\bar{\text{As}}}+\dot{\text{Zn}}\dot{\text{H}}$	$(\text{As},\Theta)_2\vert\Theta_6\vert\text{Zn}_3+\text{Zn}\,\text{H}_2\Theta_2$
538. **Conichalcite**	$(\dot{\text{Cu}},\dot{\text{Ca}})^3(\ddot{\bar{\text{P}}},\ddot{\bar{\text{As}}})+\dot{\text{Cu}}\dot{\text{H}}+\frac{1}{2}\dot{\text{H}}$	$((\text{As P})\Theta)_2\vert\Theta_6\vert(\Theta\text{u},\Theta\text{a})_3+\Theta\text{u}\,\text{H}_2\Theta_2+\frac{1}{2}\text{ aq}$
539. **Bayldonite**	$(\dot{\text{Cu}},\dot{\text{Pb}})^3\ddot{\bar{\text{As}}}+\dot{\text{Cu}}\dot{\text{H}}+\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert(\Theta\text{a},\text{Pb})_3+\Theta\text{u}\,\text{H}_2\Theta_2+\text{aq}$
540. **Euchroite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+\dot{\text{Cu}}\dot{\text{H}}+6\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_6\vert\Theta\text{u}+\Theta\text{u}\,\text{H}_2\Theta_2+6\text{ aq}$

VII. LIROCONITE GROUP. Contain $\dot{\text{Cu}}$. General formula $\dot{\text{R}}^3(\ddot{\bar{\text{P}}},\ddot{\bar{\text{As}}})+n$ aq, with mostly 2 $\dot{\text{Cu}}\dot{\text{H}}$ or 3 $\dot{\text{Cu}}\dot{\text{H}}$ accessory. Monoclinic, without a very distinct basal cleavage.

541. **Tagilite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{P}}}+\dot{\text{Cu}}\dot{\text{H}}+2\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_3\vert\Theta\text{u}_3+\Theta\text{u}\,\text{H}_2\Theta_2+2\text{ aq}$
542. **Liroconite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+(\frac{1}{3}\dot{\text{Cu}}^3+\frac{2}{3}\ddot{\bar{\text{Al}}})\dot{\text{H}}^3+9\dot{\text{H}}$	$(\text{As}\Theta)_2\vert\Theta_3\vert\Theta\text{u}_3+\text{Q}+9\text{ aq}$
543. **Pseudomalachite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{P}}}+3\dot{\text{Cu}}\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert\Theta\text{u}_3+3\,\Theta\text{u}\,\text{H}_2\Theta_2$
543A. **Ehlite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{P}}}+2\dot{\text{Cu}}\dot{\text{H}}+\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert\Theta\text{u}_3+2\,\Theta\text{u}\,\text{H}_2\Theta_2+\text{aq}$
543B. **Dihydrite**	$\dot{\text{Cu}}^3\ddot{\bar{\text{P}}}+2\dot{\text{Cu}}\dot{\text{H}}$	$(\text{P}\Theta)_2\vert\Theta_6\vert\Theta\text{u}_3+2\,\Theta\text{u}\,\text{H}_2\Theta_2$

544. Erinite	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+2\dot{\text{Cu}}\dot{\text{H}}$	$(\text{As}\Theta)_2\|\Theta_6\|\Theta\text{u}_3+2\Theta\text{u}\text{H}_2\Theta_2$
545. Cornwallite	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+2\text{Cu}\dot{\text{H}}+3\dot{\text{H}}$	$(\text{As}\Theta)_2\|\Theta_6\|\Theta\text{u}_3+2\Theta\text{u}\text{H}_2\Theta_2+3\text{ aq}$

VIII. CHALCOPHYLLITE GROUP. Contain $\dot{\text{Cu}}$. A perfect basal cleavage.

546. Tyrolite	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+2\text{Cu}\dot{\text{H}}+7\dot{\text{H}}$	$(\text{As}\Theta)_2\|\Theta_6\|\Theta\text{u}_3+2\Theta\text{u}\text{H}_2\Theta_2+7\text{ aq}$
547. Clinoclasite	$\dot{\text{Cu}}^3\ddot{\bar{\text{As}}}+3\dot{\text{Cu}}\dot{\text{H}}$	$(\text{As}\Theta)_2\|\Theta_6\|\Theta\text{u}_3+3\Theta\text{u}\text{H}_2\Theta_2$
548. Chalcophyllite	*a* $\text{Cu}^3\ddot{\bar{\text{As}}}+5\text{Cu}\dot{\text{H}}+7\dot{\text{H}}$	$(\text{As}\Theta)_2\|\Theta_6\|\Theta\text{u}_3+5\Theta\text{u}\text{H}_2\Theta_2+7\text{ aq}$
	b $\dot{\text{Cu}}^6\ddot{\bar{\text{As}}}+3\dot{\text{Cu}}\dot{\text{H}}+9\dot{\text{H}}$	$\text{As}_2\|\Theta_{10}\|\Theta\text{u}_6+3\Theta\text{u}\text{H}_2\Theta_2+9\text{ aq}$

B. Phosphates and Arsenates of Bases wholly, or in part, in the Sesquioxyd state

(1) Oxygen ratio for $(\dot{\text{R}}^3, \ddot{\bar{\text{R}}})$, $(\ddot{\bar{\text{P}}}, \ddot{\bar{\text{As}}})=3:5$, with water and sometimes other accessory constituents. Plumbogummite is of uncertain relations.

549. Berlinite	$\ddot{\bar{\text{Al}}}\ddot{\bar{\text{P}}}+\tfrac{1}{2}\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|\beta\text{Al}_2+\tfrac{1}{2}\text{ aq}$
550. Callainite	$\ddot{\bar{\text{Al}}}\ddot{\bar{\text{P}}}+5\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|\beta\text{Al}_2+5\text{ aq}$
551. Lazulite	$\ddot{\bar{\text{Al}}}\ddot{\bar{\text{P}}}+\dot{\text{Mg}}\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|\beta\text{Al}_2+\text{MgH}_2\Theta_2$
552. Barrandite	$(\ddot{\bar{\text{Al}}}, \ddot{\bar{\text{Fe}}})\ddot{\bar{\text{P}}}+4\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|\beta(\text{Al}, \text{Fe})_2+4\text{ aq}$
553. Scorodite	$\ddot{\bar{\text{Fe}}}\ddot{\bar{\text{As}}}+4\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|\beta\text{Fe}_2+4\text{ aq}$
554. Wavellite	$\ddot{\bar{\text{Al}}}\ddot{\bar{\text{P}}}+\tfrac{1}{3}\ddot{\bar{\text{Al}}}\dot{\text{H}}^3+5\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|\beta\text{Al}_2+\text{Q}+5\text{ aq}$
555. Trolleite	$\ddot{\bar{\text{Al}}}\ddot{\bar{\text{P}}}+\tfrac{1}{3}\ddot{\bar{\text{Al}}}\dot{\text{H}}^3$	$(\text{P}\Theta)_2\|\Theta_6\|\beta\text{Al}_2+\beta\text{Al}\text{H}_2\Theta_2$
556. Plumbogummite	(?) $\dot{\text{Pb}}^3\ddot{\bar{\text{P}}}+6\ddot{\bar{\text{Al}}}\dot{\text{H}}^3$	$(\text{P}\Theta)_2\|\Theta_6\|\text{Pb}_3+18\beta\text{Al}\text{H}_2\Theta_2$
557. Calcioferrite	$(\ddot{\bar{\text{Fe}}}, \dot{\text{Ca}}^3)\ddot{\bar{\text{P}}}+\tfrac{1}{3}\ddot{\bar{\text{R}}}\dot{\text{H}}^3+4\dot{\text{H}}$	$(\text{P}\Theta)_2\|\Theta_6\|(\Theta\text{a},\beta\text{Fe})_3+\tfrac{1}{3}\beta\text{R}\text{H}_2\Theta_2+4\text{ aq}$
558. Pharmacosiderite	$\ddot{\bar{\text{Fe}}}\ddot{\bar{\text{As}}}+\tfrac{1}{3}\ddot{\bar{\text{Fe}}}\dot{\text{H}}^3+4\dot{\text{H}}$	$(\text{As}\,\text{O})_2\|\Theta_6\|\beta\text{Fe}_2+\beta\text{Fe}\text{H}_2\Theta_2+4\text{ aq}$

(2) O. ratio for $(\dot{\text{R}}^3, \ddot{\bar{\text{R}}})$, $\ddot{\bar{\text{P}}}=4:5$.

559. Cirrolite	$(\tfrac{1}{3}\dot{\text{Ca}}^3+\tfrac{1}{3}\ddot{\bar{\text{Al}}})^4\ddot{\bar{\text{P}}}^3+3\dot{\text{H}}$	$\text{P}_2\Theta\|\Theta_6\|(\tfrac{1}{3}\Theta\text{a}+\tfrac{1}{3}\beta\text{Al})_3+\text{aq}$

Trolleite (555), *calcioferrite* (557), and *pharmacosiderite* (558), have the O. ratio 4 : 5, and if part of the alumina or iron is not present as an accessory hydrate, they should be included in this group. *Wavellite* (554) is also near it.

(3) O. ratio for $(\dot{\text{R}}^3, \ddot{\bar{\text{R}}})$, $(\ddot{\bar{\text{P}}}, \ddot{\bar{\text{As}}})=1:1$; but doubtful.

560. Childrenite	$(\tfrac{4}{7}(\dot{\text{Fe}}, \dot{\text{Mn}})^3+\tfrac{3}{7}\ddot{\bar{\text{Al}}})^5\ddot{\bar{\text{P}}}^3+15\dot{\text{H}}$	$\text{P}_2\|\Theta_{10}\|(\tfrac{4}{7}(\text{Fe}, \text{Mn})+\tfrac{3}{7}\beta\text{Al})_5+5\text{ aq}$
561.? Attacolite	$\ddot{\bar{\text{P}}}, \ddot{\bar{\text{Al}}}, \dot{\text{Ca}}, \dot{\text{Mn}}, \dot{\text{Fe}}, \dot{\text{H}}$	

(4) O. ratio for $(\dot{\text{R}}^3, \ddot{\bar{\text{R}}})$, $(\ddot{\bar{\text{P}}}, \ddot{\bar{\text{As}}})=6:5$.

562. Augelite	$\ddot{\bar{\text{Al}}}^2\ddot{\bar{\text{P}}}+3\dot{\text{H}}$	$\beta\text{Al}_4\Theta\|\Theta_{10}\|\text{P}_2+3\text{ aq}$
563. Turquois	$\ddot{\bar{\text{Al}}}^2\ddot{\bar{\text{P}}}+5\dot{\text{H}}$	$\beta\text{Al}_4\Theta\|\Theta_{10}\|\text{P}_2+5\text{ aq}$
564. Peganite	$\ddot{\bar{\text{Al}}}^2\ddot{\bar{\text{P}}}+6\dot{\text{H}}$	$\beta\text{Al}_4\Theta\|\Theta_{10}\|\text{P}_2+6\text{ aq}$
565. Fischerite	$\ddot{\bar{\text{Al}}}^2\ddot{\bar{\text{P}}}+8\dot{\text{H}}$	$\beta\text{Al}_4\Theta\|\Theta_{10}\|\text{P}_2+8\text{ aq}$
566. Tavistockite	$(\ddot{\bar{\text{Al}}}, \text{Ca}^3)^2\ddot{\bar{\text{P}}}+3\dot{\text{H}}$	$(\Theta\text{a}, \beta\text{Al})_4\Theta\|\Theta_{10}\|\text{P}_2+3\text{ aq}$
567. Chenevixite	$(\ddot{\bar{\text{Fe}}}, \dot{\text{Cu}}^3)^2\ddot{\bar{\text{As}}}+3\dot{\text{H}}$	$(\Theta\text{u}, \beta\text{Fe})_4\Theta\|\Theta_{10}\|\text{As}_2+3\text{ aq}$
568 Dufrenite	$\ddot{\bar{\text{Fe}}}^2\ddot{\bar{\text{P}}}+2\tfrac{1}{2}\dot{\text{H}}$	$\beta\text{Fe}_4\Theta\|\Theta_{10}\|\text{P}_2+\tfrac{1}{2}\text{ aq}$
569. Cacoxenite	(?) $\ddot{\bar{\text{Fe}}}^2\ddot{\bar{\text{P}}}+12\dot{\text{H}}$	$\beta\text{Fe}_4\Theta\|\Theta_{10}\|\text{P}_2+12\text{ aq}$

570. Arseniosiderite	$(\mathrm{\bar{F}e}, \mathrm{\dot{C}a}^3)^2\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s} + 6\,\dot{\mathrm{H}}$	$(\mathrm{\bar{C}a}, \beta\mathrm{\bar{F}e})_6\, \Theta \,\vert\, \Theta_{16} \,\vert\, \mathrm{As}_2 + 6\,\mathrm{aq}$
571. Evansite	$\mathrm{\bar{A}l}^3\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}} + \mathrm{\bar{A}l}\,\dot{\mathrm{H}}^3 + 15\,\dot{\mathrm{H}}$	$\beta\mathrm{\bar{A}l}_6\, \Theta \,\vert\, \Theta_{16} \,\vert\, \mathrm{P}_2 + 3\,(\beta\mathrm{\bar{A}l}\,\mathrm{H}_6\Theta_6) + 15\,\mathrm{aq}$
572. Torbernite	$\mathrm{\bar{U}}^3\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}} + \mathrm{\dot{C}u}\,\dot{\mathrm{H}} + 7\,\dot{\mathrm{H}}$	$\beta\mathrm{\bar{U}}_6\, \Theta \,\vert\, \Theta_{16} \,\vert\, \mathrm{P}_2 + \mathrm{\bar{C}u}\,\mathrm{H}_2\Theta_2 + 7\,\mathrm{aq}$
573. Autunite	$\mathrm{\bar{U}}^3\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}} + \mathrm{\dot{C}a}\,\dot{\mathrm{H}} + 7\,\dot{\mathrm{H}}$	$\beta\mathrm{\bar{U}}_6\, \Theta \,\vert\, \Theta_{16} \,\vert\, \mathrm{P}_2 + \mathrm{\bar{C}a}\,\mathrm{H}_2\Theta_2 + 7\,\mathrm{aq}$

(5) O. ratio for $(\dot{\mathrm{R}}^3, \mathrm{\bar{R}}), (\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}) = 3 : 2$.

574. Amphithalite	$(\mathrm{\bar{A}l}, \mathrm{\dot{C}a}^3)^5\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}{}^2 + 7\,\dot{\mathrm{H}}$	$(\mathrm{\bar{C}a}, \beta\mathrm{\bar{A}l})_{15}\, \Theta_5 \,\vert\, \Theta_{20} \,\vert\, \mathrm{P}_4 + 7\,\mathrm{aq}$
575. Sphærite	$\mathrm{\bar{A}l}^5\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}{}^2 + 15\,\dot{\mathrm{H}}$	$\beta\mathrm{\bar{A}l}_{15}\, \Theta_5 \,\vert\, \Theta_{20} \,\vert\, \mathrm{P}_4 + 16\,\mathrm{aq}$
576. Borickite	$(\mathrm{\bar{F}e}, \mathrm{\dot{C}a}^3)^5\, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}{}^2 + 15\,\dot{\mathrm{H}}$	$(\mathrm{\bar{C}a}, \beta\mathrm{\bar{F}e})_{15}\, \Theta_5 \,\vert\, \Theta_{20} \,\vert\, \mathrm{P}_4 + 15\,\mathrm{aq}$

C. Phosphates or Arsenates combined with Sulphates.

580. Diadochite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \dddot{\mathrm{S}}, \mathrm{\bar{F}e}, \dot{\mathrm{H}}$
581. Pitticite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}, \dddot{\mathrm{S}}, \mathrm{\bar{F}e}, \dot{\mathrm{H}}$
582. Beudantite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}, \dddot{\mathrm{S}}, \mathrm{\bar{F}e}, \mathrm{\dot{P}b}, \dot{\mathrm{H}}$
583. Lindackerite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}, \dddot{\mathrm{S}}, \mathrm{\dot{C}u}, \mathrm{\dot{N}i}, \dot{\mathrm{H}}$
584. Svanbergite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \dddot{\mathrm{S}}, \mathrm{\bar{A}l}, \mathrm{\dot{C}a}, \mathrm{\dot{N}a}, \dot{\mathrm{H}}$
585. Picite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \dddot{\mathrm{S}}, \mathrm{\dot{F}e}, \mathrm{\dot{M}n}, \dot{\mathrm{H}}$

D. Antimonates.

586. Bindheimite	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{S}}\mathrm{b}, \mathrm{\dot{P}b}, \dot{\mathrm{H}}$

In the preceding formulas the value of Q may be learned from the corresponding formula in the other column. In many of the phosphates of copper the member $n\,\mathrm{\dot{C}u}\,\dot{\mathrm{H}}$ is made an accessory, as done by Rammelsberg and others.

515. STERCORITE. Stercorite *Herapath*, Q. J. Ch. Soc., 1849. Microcosmic Salt. Native Salt of Phosphorus.

In crystalline masses and nodules. G.=1·6151. Lustre vitreous. Color white, stained yellowish-brown. Transparent. Fragile. Not efflorescent. Easily soluble in hot and cold water.

Comp.—$\mathrm{\dot{N}a}\,\mathrm{NH^4O}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}} + 9\,\dot{\mathrm{H}}$=Phosphoric acid 34·05, ammonia 12·40, soda 14·92, water 38·63=100. Analysis by T. J. Herapath (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$ 34·325 Am. 7·680 $\mathrm{\dot{N}a}$ 15·752 $\dot{\mathrm{H}}$ 42·243=100.

Mixed with about 9 p. c. of impurities, consisting of organic matters along with chlorid of sodium, carbonate of lime, carbonate of magnesia, phosphate of lime, sand, etc.

Pyr., etc.—B.B. intumesces, blackens, and gives off water and ammonia, colors the flame momentarily a faint green, and fuses to a transparent colorless glass, soluble in boiling water.

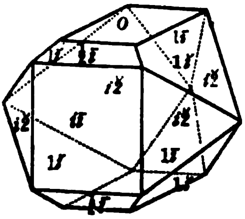
Obs.—Found in guano at the island of Ichaboe on the west coast of Africa, and named from the Latin *stercus*, *dung*.

This species is identical with the *Salt of Phosphorus*, used as a flux in blowpipe analysis.

516. STRUVITE. Struvit *Ulex*, Œfv. Ak. Stockh., 1845, iii. 32, Ann. Ch. Pharm., lxvi. 41 Guanite *E. F. Teschemacher*, Phil. Mag., III. xxviii. 546, 1846.

Orthorhombic. Hemihedral, two opposite sides having unlike planes $I \wedge I$=101° 42′, $O \wedge$ 1-ī=132° 32′; $a : b : c$=1·0900 : 1 : 1·2283. Observed planes as in the annexed figure.

458



$O \wedge$ 1-ĭ=138° 25′ | i-2̆ $\wedge$ i-2̆, ov. i-ī,=63° 8′
$O \wedge$ ½-ī=151 25 | 1-ĭ $\wedge$ 1-ĭ, ov. O,=96 50
$O \wedge$ i-ī=90 | ½-ī $\wedge$ ½-ī, ov. i-ī,=57 10

Cleavage: O, perfect. Twins: composition-face i-ī.

H.=2. G.=1·65–1·7. Color slightly yellowish to brown; white. Lustre vitreous. Translucent; sometimes opaque. Brittle. Tasteless, being but slightly soluble.

Comp.—N H^4 O $\dot{M}g^2$ $\ddot{\bar{P}}$+12 $\dot{H}$=Phosphoric acid 29·0, magnesia 16·3, ammonia 10·6, water 44·1 =100. Ulex obtained (Jahrb. Min. 1851, 51):

$\ddot{\bar{P}}$	$\dot{M}g$	$\dot{F}e$	$\dot{M}n$	Am. $\dot{H}$
28·56	13·46	3·06	1·12	53·76

Pyr., etc.—In the closed tube gives off water and ammonia and becomes opaque. B.B. colors the flame green, and fuses easily to an enamel, which, heated with cobalt solution, assumes a beautiful purple color. Soluble in acids.

Obs.—Found in guano from Saldanha Bay, coast of Africa, imbedded in patches of crystals; also under an old church in Hamburg, where quantities of cattle dung existed in the soil above a bed of peat which contained the crystals. This salt forms when a tribasic phosphate and a salt of ammonia are dissolved together, and a salt of magnesia is added to the mixture.

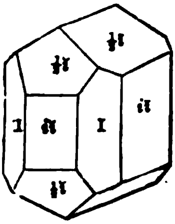
The dimensions of the crystals are nearly those of barytes if 1-ĭ be taken as ½-ĭ.

Named after the Russian statesman v. Struve.

517. HAIDINGERITE. *Turner* Edinb. J. Sci., iii. 303, 1825.

Orthorhombic. $I \wedge I$=100° (80° over i-ĭ), $O \wedge$ 1-ī=148° 16′; $a : b : c$ =0·595 : 1 : 1·1918. Observed planes: vertical, I, i-ī, i-ĭ; domes, ½-ī, 2-ī, ½-ĭ, 1-ĭ; octahedral, 4-2̆, ⅘-⅘. ½-ī $\wedge$ ½-ī, top,=146° 53′, 1-ĭ $\wedge$ 1-ĭ=126° 58′, $I \wedge$ i-ī=140°, $I \wedge$ i-ĭ=130°. Cleavage: i-ĭ highly perfect. Mostly in minute crystals aggregated into botryoidal forms and drusy crusts.

459



H.=1·5–2·5. G.=2·848. Lustre vitreous. Streak white. Color white. Transparent—translucent. Sectile; thin laminæ slightly flexible.

Comp.—(⅔ $\dot{C}a$+⅓ $\dot{H}$)^3 $\ddot{\bar{\bar{A}}}s$+3 $\dot{H}$=Arsenic acid 58·1, lime 28·3, water 13·6=100. Turner (l. c.) obtained, arsenate of lime 85·681, and water 14·319. Dissolves easily in nitric acid.

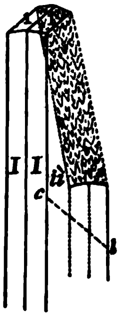
Pyr.—B.B. like pharmacolite.

Obs.—Supposed to be from Baden or Joachimsthal, according to R. P. Greg, Jr., whose cabinet contained the only specimen that has been observed; probably the latter place, according to Vogl (Min. Joach., 186). It is associated with pharmacolite.

Named after W. Haidinger.

518. BRUSHITE. *G. E. Moore*, Proc. Acad. Cal., iii. 167, 1864, Am. J. Sci., II. xxxix. 1865.

Monoclinic. C=62° 45′, $I \wedge I$=142° 26′; $a : b : c$=0·5396 : 1 : 2·614



460

I ∧ *i-i*=108° 47′, 1 ∧ *i-i*=101° 40′, 1 ∧ 1=156° 46′ (156° 20′ by approximate measurement), –1 ∧ –1 (unobserved planes) = 164° 22′, angle between edge *I* / *I* and lines of cross cleavage *cl* (=*O* on orthodiagonal section or plane *i-i*) 117°—117½°, and between same edge *I* / *I* and edge 1 / 1 (=*i-i* on 1-*i*)= 95°—95½°; whence *O* ∧ 1-*i*=about 147° 30′, Dana. Cleavage: clinodiagonal, perfect and pearly; *O* (parallel to *cl*) perfect, crystals often breaking transversely along this plane. Crystals small and slender. Also concretionary massive, consisting of lamellar individuals, and having pearly cleavages.

H.=2—2·5. G.=2·208. Lustre of *i-i* pearly, elsewhere vitreous, and in part splendent; when massive, earthy, or more or less resinous. Colorless to pale yellowish. Transparent—translucent.

Comp.—$(\frac{2}{3}\dot{C}a+\frac{1}{3}\dot{H})^3\overset{\cdots}{\bar{P}}+4\dot{H}$, or, of the general formula, $\dot{R}^3\overset{\cdots}{\bar{P}}+aq$. Analyses: 1, 2, Moore (l. c.); 3, Julien (ib., xl. 379):

	$\overset{\cdots}{\bar{P}}$	$\dot{C}a$	$\dot{H}$
1. Aves I.	41·50	32·65	26·33=100·48 Moore.
2. "	41·32	32·73	26·40=100·45 Moore.
3. Sombrero	39·95	32·11	25·95, $\ddot{\bar{A}}l$, $\ddot{\bar{F}}e$ 0·33, $\dddot{S}$ 0·78, hygrosc. 1·23=100·35 Julien.

Pyr., etc.—Heated in a closed tube whitens, and at an incipient red heat gives off water. B.B. in the platinum forceps fuses easily with intumescence, tinging the flame green; the button crystalline with brilliant facets on cooling. Dissolves readily in dilute nitric and muriatic acids.

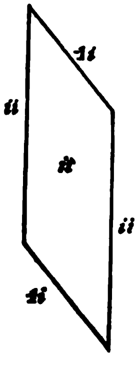
Obs.—Occurs on the rock guano of Aves Island and Sombrero in the Caribbean Sea, in groups and crusts consisting of delicate and mostly transparent crystals. Named after G. J. Brush.

The species may be regarded as isomorphous with *vivianite*; 2*a* : *b* : ½*c* of brushite equalling 1·0792 : 1 : 1·307, which is very near the ratio in vivianite given on page 557. The two agree in formula, except that one has 4 $\dot{H}$ and the other 8 $\dot{H}$. It is isomorphous also with pharmacolite if the prism *I* (142° 26′) be regarded as corresponding to *i*-2 of the latter, the angle of which is 141° 8′.

519. METABRUSHITE. *A. A. Julien*, Am. J. Sci., II. xl. 371, 1865. Zeugite *Julien*, ib., p. 373. Ornithite *Julien*, ib., p. 377.

Monoclinic, with pearly clinodiagonal cleavage, as in brushite. Occurring planes, the clinodiagonal *i-i*, with the two orthodiagonal *i-i* and –1-*i*, giving the section in the annexed figure. Crystals usually having *i-i* broad and even, but not shining, and the other planes deeply furrowed and rounding into one another, as in fig. 462; sometimes thin and flattened parallel to *i-i*. Angle *i-i* ∧ –1-*i* varying, 38°—46°, mostly 38°—42°; and 38° in the best crystals (Dana). Cleavage: clinodiagonal perfect.

H. = 2·5—3. G. = 2·288, 2·356, 2·362. Lustre feeble, except on the cleavage-face, which is pearly, somewhat resinous in fracture. Color pale yellow, buff, to nearly white; streak uncolored. Translucent to transparent. Brittle.



461

462

Comp.—$(\frac{2}{3}\dot{\mathrm{C}}\mathrm{a}+\frac{1}{3}\dot{\mathrm{H}})^3\ddot{\mathrm{P}}+3\dot{\mathrm{H}}$=Phosphoric acid 41·90, lime 35·42, water 20·68=100; or same as brushite, excepting one less of water. Analyses: 1, Julien (l. c.):

	$\ddot{\mathrm{P}}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dddot{\mathrm{Al}}$, $\dddot{\mathrm{Fe}}$	$\dot{\mathrm{H}}$	$\dddot{\mathrm{S}}$
1. (⅔)	42·72	32·98	0·52	0·79	21·83	0·05, hygrosc. 1·50=100·39 Julien.

The water included some organic matter.

Pyr., etc.—Same as for brushite.

Obs.—From Sombrero, coating cavities in guano and the coral rock altered by filtrations from the overlying guano. Crystals sometimes 1 inch long and ¼ inch broad.

This compound, as Julien states, has been recognized as an artificial salt by Raewsky and Berzelius

Alt.—The crystals of metabrushite from Sombrero are often hollow from the removal of the interior, and otherwise altered. Julien describes the following varieties:

1. H.=3·25. G.=2·971. The crust of the hollow crystals thin, and surfaces within and without often coated by minute rhombs of calcite; the *zeugite* of Julien. 2. Crust rather thicker, without a glittering surface of calcite rhombs. 3. G.=2·988—3·030; in narrow blades sometimes an inch long; the crust thick, the crystals being nearly or quite solid.

4. *Ornithite* of Julien, from Sombrero (l. c., p. 377), appears also to be altered metabrushite, its crystals presenting the same forms and habit, but usually quite small and very thin parallel to the orthodiagonal; also sometimes thin parallel to the clinodiagonal, and acute rhombic in section; angle *i-i* ∧ −1-*i*=about 38°; H.=2·5. The analysis given was made on only one-tenth of a gram, and the results are hence unavoidably doubtful.

Analyses of 1, 3, 4, afforded Julien (the water including some organic matter):

	$\ddot{\mathrm{P}}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dddot{\mathrm{Fe}}$, $\dddot{\mathrm{Al}}$	$\dddot{\mathrm{S}}$	$\ddot{\mathrm{C}}$	F	Na Cl
Var. 1. *Zeugite* (⅔)	46·55	44·21	3·02	3·59	0·66	0·19	0·24	*tr.*	1·08=99·54 Julien.
Var. 3. "	43·24	48·87	3·98	0·56	1·02	0·18	1·74	*tr.*	? =99·59 Julien.
Var. 4. *Ornithite*	40·14	45·77	9·45	—	4·62	—	—	—	—=99·98 Julien.

In 1, O. ratio for $\ddot{\mathrm{P}}$, $\dot{\mathrm{C}}\mathrm{a}$ (impurities excluded)=2·95 : 1·56; ornithite corresponds nearly to the formula $\dot{\mathrm{C}}\mathrm{a}^3\ddot{\mathrm{P}}+2$ aq.

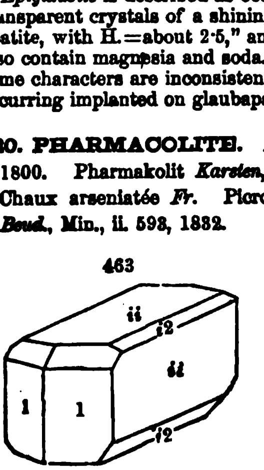
There occur also hemispherical stellated groups of white crystals, as altered ornithite, which Mr. Julien has not analyzed, but supposed to be the same compound *minus* the water. One crystal of the so-called ornithite examined by the author had on its edges and surface microscopic tufts of acicular crystals.

Epiglaubite and crystallized *Glaubapatite* of Shepard (Am. J. Sci., II. xxii. 96, 1856). One or the other of these may be metabrushite or brushite. Glaubapatite has already been remarked upon on page 535. It may be added that there is further proof that no such guano compound exists (combination of sulphate of soda and phosphate of lime) in that A. A. Julien has found no evidence of it in his investigations. His results suggest that Shepard's soda may have come from common salt present, and his sulphuric acid from sulphate of lime.

Epiglaubite is described as occurring in "small aggregates or interlaced masses of minute semi-transparent crystals of a shining vitreous lustre, which are always implanted on druses of glaubapatite, with H.=about 2·5," and as being "a largely hydrate phosphate, chiefly of lime, and may also contain magnesia and soda." It is not impossible that the mineral is metabrushite, although some characters are inconsistent with such a conclusion. If so, the name *epiglaubite* (meaning occurring implanted on glaubapatite) is inapplicable, and should be rejected.

520. PHARMACOLITE. Arseniksaurer Kalk (von Wittichen) *Selb*, Scherer's J., iv. 537, 1800. Pharmakolit *Karsten*, Tab., 75, 1800. Arsenikblüthe *Wern.*, pt. Arseniate of Lime. Chaux arseniatée *Fr.* Picropharmacolit *Stromeyer*, Gilb. Ann., lxi. 185, 1819. Arsenicite *Beud.*, Min., ii. 593, 1832.

463



Monoclinic. *I* ∧ *I*=111° 6′, *i*-2 ∧ *i*-2=141° 8′, *i*-*ì* ∧ *i*-2=109° 26′, *i*-*i* ∧ *i*-*ì*=90°, 1 ∧ 1=117° 24′, *i*-*ì* ∧ 1=121° 28′, *i*-*i* ∧ 1=95° 46′, *i*-*i*, on edge 1/1,=83° 14′. Cleavage: *i*-*ì* eminent. One of the faces 1 often obliterated by the extension of the other. Surfaces *i*-*i* and *i*-2 usually striated parallel to their mutual intersection. Rarely in crystals; commonly in delicate silky fibres or acicu lar crystallizations, in stellated groups. Also botryoidal and stalactitic and sometimes massive.

H.=2—2·5. G.=2·64—2·73. Lustre vitreous; on *i-ī* inclining to pearly. Color white or grayish; frequently tinged red by arsenate of cobalt. Streak white. Translucent—opaque. Fracture uneven. Thin laminæ flexible.

Comp.—$(\frac{2}{3}\dot{\mathrm{C}}\mathrm{a}+\frac{1}{3}\dot{\mathrm{H}})^3\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}+5\dot{\mathrm{H}}$=Arsenic acid 51·1, lime 24·9, water 24·0=100. Analyses: 1, Klaproth (Beitr., iii. 277); 2, John (Ch. Unters., ii. 221); 3, Rammelsberg (Pogg., lxii. 150):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$
1. Wittichen	50·54	25·00	24·46=100 Klaproth.
2. Andreasberg	45·68	27·28	23·86=96·82 John.
3. Glücksbrunn	51·58	23·59	23·40, $\dot{\mathrm{C}}\mathrm{o}$, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}$ 1·43=100 Ramm.

The cobalt in the last is attributed to a mixture with cobalt bloom. Turner obtained for a specimen of unknown locality (Brewst. J., iii. 306) Arsenate of lime 79·01, water 20·99=100. The name *arsenicite* is applied by Beudant to the mineral analyzed by John on the ground of the analysis alone.

Pyr., etc.—In the closed tube yields water and becomes opaque. B.B. in O.F. fuses with intumescence to a white enamel, and colors the flame light blue (arsenic). On charcoal in R.F. gives arsenical fumes, and fuses to a semi-transparent globule, sometimes tinged blue from traces of cobalt. The ignited mineral reacts alkaline to test paper. Insoluble in water, but readily soluble in acids.

Obs.—Found with arsenical ores of cobalt and silver. Has been found at Wittichen, Baden, in crystals; at St. Marie aux Mines in the Vosges, in botryoidal or globular groups; at Andreasberg in the Harz, and at Riechelsdorf and Bieber in Hessia; at Glücksbrunn in Thuringia; at Joachimsthal in Bohemia.

This species was named, in allusion to its containing arsenic, from φάρμακον, *poison*.

Viewing the form as above, it is remotely homœomorphous with cobalt bloom and vivianite.

520A. *Picropharmacolite* of Stromeyer, from Riechelsdorf (l. c.), contains Arsenic acid 46·97, lime 24·65, magnesia 3·22, oxyd of cobalt 1·00, water 23·98=99·82, affording the formula $(\dot{\mathrm{C}}\mathrm{a}, \dot{\mathrm{M}}\mathrm{g})^5\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}^2+12\dot{\mathrm{H}}$, Ramm.; but it is probably impure pharmacolite. The prefix *picro*, from πικρος, *bitter*, alludes to the magnesia present.

521. CHURCHITE. A new British mineral containing cerium *A. H. Church*, Ch. News, xii. 121, 1865. Churchite *C. G. Williams*, ib. 183. Hydrated Cerous Phosphate *Church*, J. Ch. Soc., II. iii. 259, 1865.

Monoclinic? In fan-like aggregations of minute crystals. Cleavage perfect in one direction (the clinodiagonal?); also radiated columnar.

H.=3. G.=3·14? Lustre vitreous; pearly on cleavage plane; color pale smoke-gray, tinged with flesh-red. Streak white. Transparent to translucent. Fracture conchoidal. Doubly refracting.

Comp.—O. ratio for $\dot{\mathrm{R}}, \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}, \dot{\mathrm{H}}=3:5:4$; $(\frac{5}{6}\dot{\mathrm{C}}\mathrm{e}+\frac{1}{6}\dot{\mathrm{C}}\mathrm{a})^3\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+4\dot{\mathrm{H}}$=Phosphoric acid 27·78, ceria 52·73, lime 5·47, water 14·07=100. Analysis · Church (J. Ch. Soc., II. iii. 262):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dot{\mathrm{C}}\mathrm{e}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$
28·48	51·87	5·42	14·93=100·70 Church.

Pyr., etc.—B.B. in tube yields acid water, becoming opaque. In outer flame becomes reddish, and difficultly soluble. With borax in outer flame gives a bead which is orange-yellow and opaline while hot, and colorless or slightly amethystine when cold.

Obs.—Occurs at Cornwall, in a copper lode, as a coating $\frac{1}{16}$ of an inch thick on quartz and argillaceous schist. C. G. Williams (l. c.) has proved churchite to contain didymium. Church obtained a trace of fluorine. Cleavage takes place parallel to a rhombic plane, which Maskelyne calls the *basal* plane.

Named after Prof. A. H. Church, of Cirencester, Eng

522. HŒRNESITE. Hörnesit *Haid.*, Verh. G. Reichs., 41, 1860, Ber. Ak. Wien, xl 18 1860.

Monoclinic. Cleavage eminent in one direction, like talc. Also columnar; stellar-foliated.

H.=0·5–1. G.=2·474. Cleavage pearly. Color snow-white. Folia transparent, flexible.

Comp.—$\dot{\text{M}}\text{g}^3\,\ddot{\bar{\text{A}}}\text{s}+8\,\dot{\text{H}}$=Arsenic acid 46·6, magnesia 24·3, water 29·1=100, analogous to vivianite. Analysis: v. Hauer (l. c.):

$\ddot{\bar{\text{A}}}\text{s}$ 46·33 $\dot{\text{M}}\text{g}$ 24·54 $\dot{\text{H}}$ 29·07=99·94.

Pyr., etc.—In a glass tube gives much water. B.B. fuses easily, and on charcoal affords the odor of arsenic. Insoluble in water and easily soluble in acids.

Obs.—First distinguished by Kenngott in minerals from the Bannat (vicinity either of Cziklowa or Orawitza) in the Imperial Mineral Cabinet at Vienna. Occurs in a coarsely granular calcite, containing also some garnets.

Named after Dr. Hörnes.

523. RŒSSLERITE. *R. Blum*, Jahresb. Wett. Ges. Hanau, 32, 1861.

In thin crystalline plates, with columnar or fibrous structure. Cleavage apparent in one direction. Also in vermiform efflorescences.

H.=2–3. G.= ? Lustre vitreous to dull. Colorless or white. Transparent to translucent. Becomes opaque and dull on exposure.

Comp.—$(\frac{2}{3}\dot{\text{M}}\text{g}+\frac{1}{3}\dot{\text{H}})^3\,\ddot{\bar{\text{A}}}\text{s}+12\,\dot{\text{H}}$=Arsenic acid 39·65, magnesia 13·80, water 46·55. Analysis by Delffs (l. c.):

$\ddot{\bar{\text{A}}}\text{s}$ 40·16 $\dot{\text{M}}\text{g}$ 14·22 $\dot{\text{C}}\text{e}$ *tr.* $\dot{\text{H}}$ 45·62

Pyr., etc.—B.B. fuses to a white enamel, and in a closed tube gives water. On charcoal gives arsenical fumes. Soluble in muriatic acid.

Obs.—Occurs in the Kupferschiefer, at Bieber, with pharmacolite and erythrite.

Named after Dr. C. Rössler of Hanau.

A mineral in monoclinic crystals occurs at Joachimsthal and Kremnitz, which, according to Tschermak (Anzeig. Ak. Wien, 1867, 218), has the composition $(\frac{2}{3}\dot{\text{M}}\text{g}+\frac{1}{3}\dot{\text{H}})^3\,\ddot{\bar{\text{A}}}\text{s}+8\,\dot{\text{H}}$, and which is probably rœsslerite.

524. VIVIANITE. Bloa Järnjord, Naturligit Berlinerblätt, Calx Martis phlogisto juncta, etc., *Cronst.*, 182, 1758. Cæruleum Berolinense nativum *Born.*, Lithoph., i. 136, 1772. 464

Surface *i-ì* smooth, others striated. Cleavage: *i-ì*, highly perfect; *i-i* and ½-*i* in traces. Often reniform and globular. Structure divergent, fibrous, or earthy; also incrusting.

H.=1·5–2. G.=2·58–2·68. Lustre, *i-ì* pearly or metallic pearly; other faces vitreous. Color white or colorless, or nearly so, when unaltered; often blue to green, deepening on exposure; usually green when seen perpendicularly to the cleavage-face, and blue transversely; the two colors mingled, producing the ordinary dirty blue color. Streak colorless to bluish-white, soon changing to indigo-blue; color of the dry powder often liver-brown. Transparent—translucent; becoming opaque on exposure. Fracture not observable. Thin laminæ flexible. Sectile.

Comp.—$\dot{F}e^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}+8\dot{H}$=Phosphoric acid 28·3, protoxyd of iron 43·0, water 28·7=100, when colorless, being isomorphous with erythrite; but changes readily, owing to oxydation of the iron; analysis afforded Rammelsberg $6(\dot{F}e^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}+8\dot{H})+\overset{\cdot\cdot\cdot}{\overline{F}}e^3\overset{\cdot\cdot\cdot\cdot\cdot}{P}^2+8\dot{H})$.

Analyses: 1, Vogel (Gilb. Ann., lix. 174); 2, Rammelsberg (Pogg., lxiv. 411); 3, Stromeyer (Unters., 274); 4, 5, Rammelsberg (Pogg., lxiv. 411); 6, Brandes (Schw. J., xxxi. 77); 7, Thomson (Min., i. 452); 8, W. Fisher (Am. J. Sci., II. ix. 84); 9, Rammelsberg (J. pr. Ch., lxxxvi. 344):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$\overset{\cdot\cdot\cdot}{\overline{F}}e$	$\dot{F}e$	$\dot{H}$

15. Barguis, *earthy, blue*	19·79	33·11	13·75	26·10, $\dot{M}g$ 7·37=100·12 Struve.
16. Allentown, N. J., "	29·65	18·45	27·62	25·60, $\dot{M}g$ 0·08=101·35 Kurlbaum.

The anglarite corresponds to the formula $\dot{F}e^4\overset{\cdot\cdot\cdot\cdot\cdot}{P}+4\dot{H}$; it is probably massive vivianite.

A vivianite from New Zealand afforded R. Pattison (Phil. Mag., III. xxv. 495):

Phos. iron 62·8, water 28·4, organic matter 2·8, silica 5·2=99·2.

Pyr., etc.—In the closed tube yields neutral water, whitens, and exfoliates. B.B. fuses at 1·5, coloring the flame bluish-green, to a grayish-black magnetic globule. With the fluxes reacts for iron. Soluble in muriatic acid.

Obs.—Occurs associated with pyrrhotite and pyrite in copper and tin veins; sometimes in narrow veins with gold, traversing gray-wacke; both friable and crystallized in beds of clay, and sometimes associated with limonite, or bog iron ore; often in cavities of fossils or buried bones.

At St. Agnes in Cornwall transparent indigo crystals have been found, 1 in. in diameter and 2 long, on pyrrhotite; at Wheal Falmouth, and near St. Just; in Devonshire, near Tavistock; at Bodenmais, and the gold mines of Vöröspatak in Transylvania, in crystals; on the promontory of Kertsch in the Black Sea, in large indistinct crystals in the interior of shells. The earthy variety, sometimes called *blue iron earth* or *native Prussian blue* (*Fer azuré*), occurs in Greenland, Syria, Carinthia, Cornwall, etc. The friable varieties in bog iron ore in several peat swamps in the Shetland Isles, at Ballagh in the Isle of Man, accompanying sometimes the horns of the elk and deer, and near an old slaughter-house in Edinburgh. At Cransac, France, in crystals formed after the burning of a coal mine.

In N. America, it occurs in *N. York*, at Harlem, in crystals accompanying stilbite and feldspar in fissures in gneiss. In *New Jersey*, at Imleytown, in dark blue crystals; at Allentown, Monmouth Co., in considerable abundance, both crystallized, in nodules, and earthy, imbedded in bog iron ore and associated with clays; at Mullica Hill, Gloucester Co. (*Mullicite*), in cylindrical masses, consisting of divergent fibres or acicular crystals; at Franklin, occasionally; it often fills the interior of belemnites and other fossils in the Ferruginous sand formation. Also in *Delaware* (see anal. 8 above), 4 m. W. of Cantwell's Bridge, and near Middletown, in Green sand, in fine large crystals which are colorless when first obtained, evidently, as Fisher observed, containing only protoxyd of iron; near Cape Henlopen, in Sussex Co. In *Maryland*, in the north part of Somerset and Worcester Cos. In *Virginia*, with bog ore in Stafford Co., and 8 or 10 m. from Falmouth, with gold and galenite. In *Canada*, with limonite at Vandreuil, abundant.

Named by Werner after J. G. Vivian, an English mineralogist who discovered the specimens in Cornwall. Werner was not aware of their identity with the *Blaueisenerde* when he gave the name.

Alt.—Becomes altered, as above stated, through the oxydation of the iron, which the analyses given illustrate. Tschermak obtained (Ber. Ak. Wien, xlix. 342) for an altered vivianite in crystals from a cabinet in Vienna, $\dddot{\mathrm{P}}$ 30·5, $\ddot{\mathrm{F}}\mathrm{e}$ 55·0, $\dot{\mathrm{N}}\mathrm{a}$ 1·5, $\dot{\mathrm{H}}$ 14·0=101. G.=2·95; lustre metallic-pearly; color on face of cleavage pinchbeck-brown, elsewhere blackish-brown; streak ochre-yellow.

Beraunite Breithaupt (Handb., 156, 1841, B. H. Ztg., 1853, 402) is of similar origin and character. It occurs in small foliated and columnar aggregations, with one perfect metallic-pearly cleavage, having H.=2; G.=2·878; color hyacinth-red to reddish-brown; streak dirty yellow. Plattner found it to be a hydrous phosphate of sesquioxyd of iron. From St. Benigna, near Beraun, in Bohemia; and reported also from Wheal Jane, near Truro, England, by Greg, associated with pure and altered vivianite.

525. SYMPLESITE. Symplesit *Breith.*, J. pr. Ch., x. 501, 1837.

Monoclinic. In form resembling erythrite. Cleavage perfect parallel with the clinodiagonal face. In minute prismatic crystals; also aggregated.

H.=2·5, nearly. G.=2·957. Lustre of cleavage-face pearly; elsewhere vitreous. Color pale indigo, inclined to celandine-green; sometimes between leek- and mountain-green. Streak bluish-white. Subtransparent to translucent.

Comp.—Supposed to be an arsenate of the protoxyd of iron.

Pyr., etc.—In the closed tube yields much water; at a high temperature some arsenous acid sublimes, imparting an acid reaction to the water, and giving a black magnetic residue. B.B. in the forceps infusible, but colors the outer flame light blue (arsenic), and becomes black and magnetic. On charcoal gives a strong arsenical odor. With the fluxes reacts for iron, and gives also traces of manganese and sulphuric acid (Plattner).

According to Breithaupt, when heated in a glass tube, it turns brown, and loses 26¼ p. c. of water. Plattner found 24¾ p. c.

Obs.—Occurs at Lobenstein in Voigtland, with spathic iron.

526. ERYTHRITE. Kobold-Blüthe *Brückmann*, Magnalia, 161, etc., 1727. Kobolt Blomma Flos Cobalti [the cryst.], Koboltbeslag [impure earthy], Cobalti minera colore rubro, etc. *Wall.*, Min., 234, 1747. 465

Schneeberg.

Surfaces *i-i* and 1-*i* vertically striated. Cleavage: *i-ì* highly perfect, *i-i* and 1-*i* indistinct. Also in globular and reniform shapes, having a drusy surface and a columnar structure; sometimes stellate. Also pulverulent and earthy, incrusting.

H.=1·5—2·5; the lowest on *i-ì*. G.=2·948. Lustre of *i-ì* pearly; other faces adamantine, inclining to vitreous; also dull and earthy. Color crimson and peach-red, sometimes pearl or greenish-gray; red tints incline to blue, perpendicular to cleavage-face. Streak a little paler than the color, the dry powder deep lavender-blue. Transparent—subtranslucent. Fracture not observable. Thin laminæ flexible in one direction. Sectile.

Var.—1. Crystallized and foliated. 2. Earthy. The latter is the *earthy cobalt bloom* (Kobaltbeschlag *Germ.*, Rhodoise *Huot*).

Comp.—$\dot{C}o^3 \ddot{\ddot{A}}s + 8\dot{H}$=Arsenic acid 38·43, oxyd of cobalt 37·55, water 24·02; $\dot{C}o$ often partly replaced by $\dot{F}e$, $\dot{C}a$, or $\dot{N}i$. Analyses: 1, Bucholz (Gehlen's J., II. ix. 308); 2, Laugier (Mem. d. Mus. d'hist., ix. 233); 3, 4, 5, Kersten (Pogg., lx. 251); 6, Lindaker (Vogl's Joach.):

	$\ddot{\ddot{A}}s$	$\dot{C}o$	$\dot{N}i$	$\dot{F}e$	$\dot{C}a$	$\dot{H}$
1. Riechelsdorf	37	39	——	——	——	22=98 Bucholz.
2. Allemont	40·0	20·5	9·2	5·5	——	24·5=99·7 Laugier.
3. Schneeberg	38·43	36·52	——	1·01	——	24·10=100·06 Kersten.
4. "	38·30	33·42	——	4·01	——	24·08=99·81 Kersten.
5. "	38·10	29·19	——	——	8·00	23·90=99·19 Kersten.
6. Joachimsthal	36·42	23·75	11·26	8·51	0·42	23·52, $\dddot{S}$ 0·86=99·74 Lindaker.

Pyr., etc.—In the closed tube yields water at a gentle heat and turns bluish; at a higher heat gives off arsenous acid, which condenses in crystals on the cool glass, and the residue has a dark gray or black color. B.B. in the forceps fuses at 2 to a gray bead, and colors the flame light blue (arsenic). B.B. on charcoal gives an arsenical odor, and fuses to a dark gray arsenid, which with borax gives the deep blue color characteristic of cobalt. Soluble in muriatic acid, giving a rose-red solution.

The *earthy cobalt bloom*, of a peach-blossom color (kobaltbeschlag), is shown by Kersten to be cobalt bloom, with some free arsenous acid. He obtained:

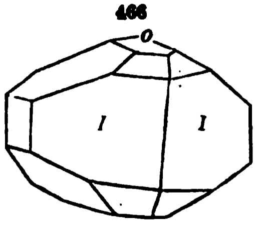
	$\ddot{\ddot{A}}s$	$\ddot{A}s'$	$\dot{C}o$	$\dot{F}e$	$\dot{H}$
1. Schneeberg	51·00	19·10	16·60	2·10	11·90=100·70.
2. Annaberg	48·10	20·00	18·30	——	12·13=98·53,

with a trace of nickel, lime, and sulphuric acid (Pogg., lx. 262).

Obs.—Occurs at Schneeberg in Saxony, in micaceous scales, stellularly aggregated; in brilliant specimens, consisting of minute aggregated crystals, at Saalfeld in Thuringia; also at Riechelsdorf in Hessia; Wolfach and Wittichen in Baden; Modum in Norway. The earthy peach-blossom varieties have been observed at Allemont in Dauphiny; in Cornwall, at the Botallack mine, St. Just, etc.; near Alston in Cumberland; near Killarney in Ireland. A perfectly green variety occurs at Platten in Bohemia, and sometimes red and green tinges have been observed on the same crystals.

Erythrite, when abundant, is valuable for the manufacture of smalt. Named from ἐρυθρός red.

466



526A. **Roselite.** The *roselite* of Levy (Ann. Phil., II. viii 439, 1824, and Ed. J. Sci., ii. 177) is probably a variety of cobalt bloom; and Kersten suggests that it may be identical with the variety in the third of his analyses above, which contains lime an element detected by Children in roselite. The form here given is from Levy. Haidinger makes it a twin with composition parallel to i-$\bar{i}$.

Orthorhombic. $I \wedge I = 132° 48'$. $O \wedge 1$-$\bar{i} = 158° 2'$. Cleavage distinct and brilliant, parallel to i-$\bar{i}$. It is deep rose-red, with the lustre vitreous, and H.$=3$.

Its only known locality is at Schneeberg in Saxony, where it has been found in small quantities on quartz. Named after G. Rose, of Berlin.

526B. **Lavendulan** (Breithaupt, J. pr. Ch., x. 505, 1837). Amorphous, with a greasy lustre, inclining to vitreous. H.$=2{\cdot}5-3$. G.$=3{\cdot}014$, Breithaupt. Color lavender-blue. Streak pale blue. Translucent. Fracture conchoidal.

Contains, according to Plattner, arsenic, and the oxyds of cobalt, nickel, and copper, with water. J. Lindaker (Jahrb. G. Reichs., iv. 555) found oxyd of copper as a prominent ingredient with the others mentioned. Fuses easily before the blowpipe, coloring the flame deep blue, and yielding a globule which becomes crystalline on cooling. On charcoal yields an arsenical odor. With the fluxes gives the reaction of cobalt. Occurs at Annaberg in Saxony, with cobalt and other ores, and is a result of their alteration.

527. ANNABERGITE. Ochra Niccoli, Niccolum calciforme, *Cronst.*, Min., 218, 1758. Nickelocker. Nickelblüthe. Nickel Ochre; Nickel Green; Arseniate of Nickel. Nickel Arseniaté. Annabergite *B & M.*, 503, 1852.

Monoclinic. In capillary crystals; also massive and disseminated. Soft. Color fine apple-green. Streak greenish-white. Fracture uneven, or earthy.

Comp.—$\dot{N}i^3 \overset{\cdots}{A}s + 8\dot{H}$ = Arsenic acid 38·6, oxyd of nickel 37·2, water 24·2=100. Analyses: 1, Berthier (Ann. Ch. Phys., xiii. 52); 2, Stromeyer (Schw. J., xxv. 220); 3–5, Kersten (Pogg., lx. 251):

	$\overset{\cdots}{A}s$	$\dot{N}i$	$\dot{C}o$	$\dot{H}$
1. Allemont	36·8	36·2	2·5	25·5=100 Berthier.
2. Riechelsdorf	36·97	37·35	—	24·32, $\dot{F}e$ 1·13, $\dddot{S}$ 0·23=100 Strom.; some $\dot{C}o$ with $\dot{N}i$.
3. Schneeberg	38·30	36·20	1·53	23·91, $\dot{F}e$ *tr.*=99·94 Kersten.
4. "	38·90	35·00	—	24·02, " 2·21=100·13 Kersten.
5. "	37·21	36·10	*tr.*	23·92, " 1·10, $\overset{\cdots}{A}s$ 0·52=98·85 Kersten.

Pyr., etc.—In the closed tube gives off water and darkens in color. B.B. fuses easily, and on charcoal gives an arsenical odor and yields a metallic button, which with borax glass gives at first a cobalt-blue glass, and later the violet to reddish-brown color characteristic of nickel; in R.F. it becomes gray from reduced nickel. Soluble in acids.

This species is probably isomorphous with erythrite.

Obs.—Occurs on smaltite at Allemont in Dauphiny, and is supposed to result from the decomposition of this ore; also at Kamsdorf, near Saalfeld; at Annaberg; at Riechelsdorf, and other mines of nickel ores. It has been occasionally observed associated with copper nickel in the cobalt mine at Chatham, Connecticut.

528. *Hydrous Bibasic Arseniate of Nickel and Cobalt.* Under this name D. Forbes describes (Phil. Mag., IV. xxv. 103) a mineral occurring in the desert of Atacama in veins in a decomposed dioryte. A few yards below the surface it passes into chloanthite, from which mineral it appears to have been derived. H.$=2{\cdot}5$. G.$=3{\cdot}086$. Structure fibro-crystalline. Lustre dull to silky or resinous Color grayish-white. Analysis afforded $\overset{\cdots}{A}s$ 44·05, $\dot{N}i$ 19·71, $\dot{C}o$ 9·24, $\dot{H}$ 26·98=99·98; from which Forbes deduces the formula $(\dot{N}i, \dot{C}o)^2 \overset{\cdots}{A}s + 8\dot{H}$, which requires $\overset{\cdots}{A}s$ 43·89, $\dot{C}o$, $\dot{N}i$ 28·63, $\dot{H}$ 27·48 =100, making it allied to pharmacolite. B.B. in the closed tube yields water, becoming darker; on charcoal fuses imperfectly, evolves arsenic fumes, leaving metallic globules of an arsenid of nickel and cobalt. With fluxes gives reactions for nickel and cobalt.

By regarding a portion of the water basic, the mineral becomes a tribasic arsenate and thus approaches annabergite. Kenngott names it *Forbesite* (Ueb., 1862–'65, 46, 1868).

529. CABRERITE. Wasserhaltige Nickeloxyd-Magnesia *J. H. Ferber*, B. H. Ztg, xxii. 306, 1863. Cabrerite *Dana*.

Monoclinic. Like erythrite in habit. Cleavage: clinodiagonal perfect. Also fibrous, concentric. Reniform and granular.

H.=2. G.=2·96. Lustre pearly on face of cleavage; silky when fibrous. Color apple-green. Translucent to transparent.

Comp.—O. ratio for $\dot{R}$, $\dddot{\bar{A}}s$, $\dot{H}$=3 : 5 : 8. $\dot{R}^3\dddot{\bar{A}}s+8\dot{H}$, in which $\dot{R}$ corresponds to $\dot{N}i$, $\dot{C}o$, $\dot{M}g$ in the ratio 5 : 1 : 4½. Analysis: Ferber (l. c.), having only a small quantity at his disposal:

$\dddot{\bar{A}}s$ 42·37 $\dot{N}i$ 20·01 $\dot{C}o$ 4·06 $\dot{M}g$ 9·29 $\dot{H}$ 25·80=101·53.

Pyr., etc.—In the closed tube yields water and becomes grayish-yellow. B.B. in R.F. infusible: on charcoal gives arsenical fumes.

Obs.—From the Sierra Cabrera, Spain, in a gangue of brown spar, which is connected with the mountain limestone and argillaceous schist. Results from the alteration of arsenids of nickel and cobalt.

530. KÖTTIGITE. Zinkarseniat *Otto Köttig*, J. pr. Ch., xlviii. 183, 1849; *Naumann*, ib., 256. Köttigite *Dana*, Min., 487, 1850.

Monoclinic, and isomorphous with erythrite, Naumann. Massive, or in crusts, with crystalline surface and fibrous structure. Cleavage: clinodiagonal perfect.

H.=2·5–3. G.=3·1. Lustre of surface of fracture silky. Color light carmine- and peach-blossom-red, of different shades. Streak reddish-white. Translucent to subtranslucent.

Comp.—$(\dot{Z}n, \dot{C}o, \dot{N}i)^3\dddot{\bar{A}}s+8\dot{H}$, or analogous to erythrite. Analysis by Köttig (l. c.):

$\dddot{\bar{A}}s$ [37·17] $\dot{Z}n$ 30·52 $\dot{C}o$ 6·91 $\dot{N}i$ 2·00 $\dot{C}a$ *tr.* $\dot{H}$ 23·40=100.

Pyr., etc.—In the closed tube gives much water, and at a higher temperature a faint crystalline sublimate of arsenous acid. B.B. fuses easily, coloring the flame blue; on charcoal in R.F. gives copious fumes of arsenic and coats the coal with oxyd of zinc; with soda the coating is much more marked, and is yellow while hot and white on cooling; this moistened with cobalt solution and heated in O.F. assumes a green color. With borax and salt of phosphorus gives a cobalt-blue glass.

Obs.—Occurs with smaltite at the cobalt mine Daniel, near Schneeberg. The color is owing partly to the arsenate of cobalt in the mineral.

531. HUREAULITE. *Alluaud*, Vauquelin, Ann. Ch. Phys., xxx. 302, 1825; *Alluaud*, Ann. d. Sci. Nat., viii. 349, 1826. *Dufrénoy*, Ann. Ch. Phys., xli. 338, 1829; *Descloizeaux* and *Damour*, ibid., III. liii. 293.

Monoclinic $I \wedge I$ (planes unobs.)=99° 21′; i-2 ∧ i-2=61°; $O \wedge I$=90° 17′, $O \wedge i$-i (=C)=90° 33′, $O \wedge$ 1-ì=138° 22′, $O \wedge$ 3-í=122° 53′, $O \wedge$ ¼-ì =174° 2′. In small crystals, isolated or grouped, the groups sometimes mammillary, or fascicled as in stilbite. Cleavage not observed. Also to a limited extent massive, compact, scaly, or imperfectly fibrous.

H.=5. G.=3·185, yellow, and 3·198, reddish, Damour. Lustre vitreous, somewhat greasy, bright. Color brownish-orange, rose-violet, and pale rose, nearly colorless. Streak similar. Transparent—translucent. Optically biaxial; axes very divergent, the plane orthodiagonal; bisectrix positive.

Var.—The (*a*) brownish-orange or yellowish, (*b*) the rose-violet, and (*c*) the pale rose, are three varieties, differing somewhat in their crystalline planes. The orange is the most common. The crystals approach in habit those of crocoisite, though of very different angles.

Comp.—O. ratio for $\dot{R}, \ddot{P}, \dot{H}=1:2:1$; whence $(\dot{M}n, \dot{F}e)^5 \ddot{P}^2+5\dot{H}$, with $\dot{M}n:\dot{F}e=5:1$, or better $(\dot{M}n, \dot{F}e, \dot{H})^3 \ddot{P}+2\dot{H}$=Phosphoric acid 39·1, protoxyd of manganese 40·2, protoxyd of iron 8·3, water 12·4=100. Analyses: 1, Dufrénoy (l. c.); 2, 3, 4, Damour (l. c.):

			$\ddot{P}$	$\dot{M}n$	$\dot{F}e$	$\dot{H}$	
1.	Limoges		38·00	32·85	11·10	18·00=99·95	Dufrénoy.
2.	"	*yellow*	37·96	41·15	8·10	12·35, quartz 0·35=99·91	Damour.
3.	"	"	38·20	42·04	6·75	12·00 " 0·50=99·49	Damour.
4.	"	*reddish*	37·83	41·80	8·73	11·60 " 0·30=100·26	Damour.

Pyr., etc.—In the closed tube gives water. B.B. fuses to a reddish-yellow crystalline pearl, brown in the outer flame, then becomes black, and the flame is colored green. Reactions of manganese and iron. Easily soluble in acids.

Obs.—Found in cavities of triphyline or its altered form heterosite, in granite, at Limoges, commune of Huréaux, France.

The crystals were first examined by Dufrénoy (l. c.), and afterward more completely by Descloizeaux (l. c.).

532. CHONDRARSENITE. Kondroarsenit *Igelström*, Œfv. Ak. Stockh., xxii. 3, 1865.

In small grains.

H.=3. Color yellow to reddish-yellow. Translucent. Brittle. Fracture conchoidal.

Comp.—An arsenate of manganese. O. ratio for $\dot{R}, \ddot{A}s, \dot{H}=2:2:1$; whence $\dot{M}n^5 \ddot{A}s+2\frac{1}{2}\dot{H}$ Analysis: Igelström (l. c.):

$\ddot{A}s$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$	
33·50	51·59	2·05	4·86	7·00,	$\ddot{C}$ *tr.*=99·00 Igelström.

Pyr., etc.—B.B. in tube decrepitates, blackens, and gives neutral water. On charcoal easily fusible to a black bead, not magnetic; in the inner flame gives arsenical fumes. With borax gives manganese reaction. Easily and completely soluble in dilute muriatic and nitric acids.

Obs.—Occurs in the Paisberg mines, Wermland, in veins of barite intersecting hausmannite.

Named from its similarity in occurrence, color, and transparency to chondrodite, while differing from it in being an arsenate.

---

533. TRICHALCITE. Trichalcit *Herm.*, J. pr. Ch., lxxiii. 212, 1858.

In radiated groups, columnar; also in dendritic forms.

H.=2·5. Lustre silky. Color verdigris-green.

Comp.—$\dot{C}u^3\ddot{A}s+5\dot{H}$. Analysis by Hermann (l. c.):

$\ddot{A}s$	$\ddot{P}$	$\dot{C}u$	$\dot{H}$
38·73	0·67	44·19	16·41=100.

Pyr., etc.—Heated decrepitates, yields much water, and becomes dark brown. B.B. on charcoal fuses in the outer flame to a pearl, and in the inner yields a bead of copper. Dissolves easily in cold muriatic acid.

Obs.—From the Turjinsk copper mine, or Beresovsk, on tetrahedrite. Resembles tyrolite.

534. THROMBOLITE. Thrombolith *Breith.*, J. pr. Ch., xv. 321, 1838.

Amorphous.

H.=3–4. G.=3·38–3·40. Lustre vitreous. Color emerald-, leek-, or dark green. Streak emerald-green. Opaque. Fracture conchoidal.

Comp.—According to an imperfect analysis by Plattner (l. c.) it contains:

$\ddot{P}$ 41·0 $\dot{C}u$ 39·2 $\dot{H}$ 16·8, besides a small amount of silica and alumina.

Pyr., etc.—In the closed tube gives much water and turns black. B.B. fuses easily and first colors the flame blue, like chlorid of copper, and later gives a dark emerald-green. On charcoal fuses to a black globule, which, after long blowing, yields globules of copper. With the fluxes reacts for copper. With boric acid and iron gives a fusible phosphid (Plattner).

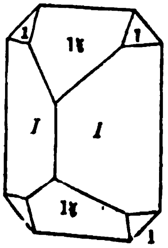
Obs.—Found with malachite in a fine-grained limestone at Retzbanya, Hungary.

535. LIBETHENITE. Olivenerz pt. Phosphorkupfererz pt. Phosphate of Copper pt. Cuivre phosphaté pt. Octaedrisches Phosphorkupfer *Leonh.*, Leonh. u. Selb's Min. Stud., 1812. Blättricher Pseudomalachite pt. *Hausm.*, Handb., 1036, 1813. Libethenit *Breith.*, Char., 267, 1823. Aphérèse *Beud.*, ii. 569, 1832. Pseudo-libethenit *Ramm.*, Min. Ch., 344, 1860.

Orthorhombic. $I \wedge I$=92° 20′, $O \wedge 1\text{-}\bar{i}$=143° 50′; $a : b : c$=0·7311 : 1 : 1·0416. Observed planes as in the annexed figure, with also the prismatic planes $i\text{-}\bar{2}$. $1\text{-}\breve{i} \wedge 1\text{-}\breve{i}$, top,=109° 52′, $1 \wedge 1$, ov. $1\text{-}\breve{i}$,=118° 12′, adj.,=120° 56′, ov. I,=90° 46′, $I \wedge 1$=135° 23′. Cleavage: diagonal, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, very indistinct. Also globular or reniform, and compact.

H.=4. G.=3·6–3·8. Lustre resinous. Color olive-green, generally dark. Streak olive-green. Translucent to subtranslucent. Fracture subconchoidal—uneven. Brittle.

467



Comp.—$\dot{C}u^4\ddot{P}+\dot{H}$, or $\dot{C}u^3\ddot{P}+\dot{C}u\dot{H}$ (Ramm.)=Phosphoric acid 29·7, oxyd of copper 66·5, water 3·8=100. Analyses; 1, Kühn (Ann. Ch. Pharm., li. 154); 2, Bergemann (Pogg., civ. 190); 3, Hermann (J. pr. Ch., xxxvii. 175); 4, Chydenius (Acta Soc. Sc. Fenn., v. 340); 5, F. Field (Chem. Gaz., June, 1859); 6, H. Müller (Qu. J. Ch. Soc., xi. 202); 7, Berthier (Ann. d. M., viii. 334); 8, Rhodius (Ann. Ch. Pharm., lxii. 371):

	$\ddot{P}$	$\dot{C}u$	$\dot{H}$
1. Libethen, *cryst.*	29·44	66·94	4·05=100·43 Kühn.
2. "	26·46	66·29	4·04, $\ddot{A}s$ 2·30=99·09 Bergemann.
3. N. Tagilsk	28·61	65·89	5·50=100 Hermann.
4. "	29·48	64·47	3·63, $\ddot{A}s$ *tr.*, $\dot{F}e$ 1·77, $\ddot{C}$ 0·82=100·22 Chydenius.
5. Coquimbo	29·31	66·42	3·74=99·47 Field
6. Congo, Africa (?)	28·89	66·98	[4·13]=100 Müller.
7. Libethen	28·7	63·9	7·4=100 Berthier.
8. Ehl	28·9	63·1	7·3=99·3 Rhodius.

G. of anal. 3=3·6–3·8; 8, 4·27.

The analysis by Berthier is identical with Rhodius's analysis of ehlite=$\dot{C}u^4\ddot{P}+2\dot{H}$, and the mineral is called *Pseudo-libethenite* by Rammelsberg, who writes the formula $\dot{C}u^3\ddot{P}+\dot{C}u\dot{H}+\dot{H}$. Beudant cites the same analysis in connection with his name Aphérèse.

Pyr., etc.—In the closed tube yields water and turns black. B.B. fuses at 2 and colors the flame emerald-green. On charcoal with soda gives metallic copper, sometimes also an arsenical odor. Fused with metallic lead on charcoal is reduced to metallic copper, with the formation of phosphate of lead, which treated in R.F. gives a crystalline polyhedral bead on cooling. With the fluxes reacts for copper. Soluble in nitric acid.

Obs.—Occurs in cavities in quartz, associated with chalcopyrite, at Libethen, near Neusohl, in Hungary; at Rheinbreitenbach and Ehl on the Rhine; at Nischne Tagilsk in the Ural; in Bolivia, S. A., with malachite; at the Mercedes mine, near Coquimbo, Chili, with tagilite and limonite; also in small quantities near Gunnis Lake in Cornwall, and near Redruth; in the Ural.

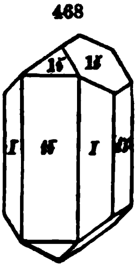
468



Orthorhombic. *I* ∧ *I*=92° 30′, *O* ∧ 1-ĭ=144° 14′; *a* : *b* : *c*=0·72 : 1 : 1·0446. Observed planes as in the figure. 1-ĭ ∧ 1-ĭ, top, =110° 50′ (110° 47′, Descl.), *i*-ĭ ∧ 1-ĭ=124° 35′, *i*-ĭ ∧ *I*=136° 15′. Cleavage: *I* and 1-ĭ in traces. Sometimes acicular. Also globular and reniform, indistinctly fibrous, fibres straight and divergent, rarely promiscuous; also curved lamellar and granular.

H.=3. G.=4·1–4·4. Lustre adamantine—vitreous; of some fibrous varieties pearly. Color various shades of olive-green, passing into leek-, siskin-, pistachio-, and blackish-green; also liver- and wood-brown; sometimes straw-yellow and grayish-white. Streak olive-green—brown. Subtransparent—opaque. Fracture, when observable, conchoidal—uneven. Brittle. Optically like libethenite, Descl.

Var.—1. *Ordinary.* (*a*) *Crystallized*; G.=4·378, Cornwall, Damour; 4·135, ib., Hermann.

(*b*) *Fibrous*; finely and divergently fibrous, of green, yellow, brown, and gray, to white colors, with the surface sometimes velvety or acicular; G.=3·913, Hermann; found investing the common variety or passing into it; called *wood-copper* or *wood-arseniate* (*Holzkupfererz*).

(*c*) *Earthy*; nodular or massive; sometimes soft enough to soil the fingers.

Comp.—$\dot{C}u^4(\dddot{\ddot{A}}s, \dddot{\ddot{P}})+\dot{H}$, or $\dot{C}u^3(\dddot{\ddot{A}}s, \dddot{\ddot{P}})+\dot{C}u\dot{H}$ =, the arsenic being to the phosphoric acid as 6 : 1, Arsenic acid 35·7, phosphoric acid 3·7, oxyd of copper 57·4, water 3·2=100, and isomorphous with libethenite. Analyses: 1, v. Kobell (Pogg., xviii. 249); 2, 3, Richardson (Thom. Min., i. 614); 4, Hermann (J. pr. Ch., xxxiii. 291); 5, Damour (Ann. Ch. Phys., III. xiii. 404); 6, Thomson (Min., i. 615); 7, Hermann (l. c.):

		$\dddot{\ddot{A}}s$	$\dddot{\ddot{P}}$	$\dot{C}u$	$\dot{H}$
1.	Cornwall, *cryst.*	36·71	3·36	56·43	3·50=100 Kobell.

7.	" "	40·50	1·00	51·03	3·83, $\ddot{\dot{F}}e$ 3·64=100 Hermann.

Pyr., etc.—In the closed tube gives water. B.B. fuses at 2, coloring the flame bluish-green, and on cooling the fused mass appears crystalline. B.B. on charcoal fuses with deflagration, gives off arsenical fumes, and yields a metallic arsenid, which with soda yields a globule of copper. With the fluxes reacts for copper. Soluble in nitric acid.

Obs.—The crystallized varieties occur disposed on, or coating, cavities of quartz in Cornwall, at Wheal Gorland, Ting Tang, Wheal Unity, and other mines near St. Day; also near Redruth; near Tavistock, in Devonshire; also in inferior specimens at Alston Moor, in Cumberland; at Camsdorf and Saalfeld in Thuringia; the Tyrol; the Bannat; Siberia; Chili; and other places.

The name olivenite alludes to the olive-green color.

None of the mineral phosphates or arsenates were distinctively recognized in ancient mineralogy. The species containing copper, if observed, were left to pass under the general names of *chrysocolla* and *malachites*. In 1747, Wallerius has, besides *Koppar-Lasur* or azurite, the two species Copper Green (malachite) and Copper Blue (chrysocolla and azurite in part), but without well-defined limits. Cronstedt, in 1758, describes the Mountain Blue as sometimes impure (terra calcarea mixta), and hence effervescing with aqua-fortis. Fontana, in 1778, announced the green *carbonate* after an analysis; and Bergmann in his Sciagraphia, 1782, recognizes only carbonate of copper, and calls wrongly the *green mica* of Werner (1780, and later *torbernite*) a chlorid. In

1786 Klaproth analyzed an *arsenate*, and Werner soon after gave it the name of *Olivenerz*; and in Werner's system of 1789 (Bergm. J., 382, 1789), Azurite, Malachite, Copper green of compact texture not effervescing with acids (chrysocolla), and Olivenerz, together with a so-called *Eisenschüssig Kupfergrün* (mostly earthy green carbonate), were the only species. Karsten's Tabellen of 1800 contains no addition to the list. But in 1801 Bournon announced, from an analysis by Chenevix, a second arsenate, afterward called *Liroconite;* Vauquelin a third, afterward named *Chalcophyllite*; Klaproth a fourth, the *Strahliges Olivenerz*, or *Clinoclase*. Klaproth also published at the same time an analysis of the first *phosphate*, now called *Pseudomalachite*; besides one of the oxychlorid *Atacamite*, which mineral had been brought from Chili as *copper sand* between 1780 and 1790, and was pronounced an oxyd by Vauquelin, and a chlorid by Karsten in his Tabellen of 1800.

537. ADAMITE. Adamine *C. Friedel*, C. R., lxii. 692, 1866.

Orthorhombic. $I \wedge I=91^\circ\ 33'$, $O \wedge 1\text{-}\bar{\imath}=143^\circ\ 40'$; $a:b:c=0{\cdot}73547:1:1{\cdot}0271$; isomorphous with olivenite. $I \wedge i\text{-}\breve{3}=161^\circ\ 43\frac{1}{2}'$, $I \wedge i\text{-}\breve{3}=161^\circ\ 25'$, $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath}=107^\circ\ 20'$, $I \wedge 1=135^\circ\ 45'$, $1 \wedge 1$, over $1\text{-}\bar{\imath}$, $=120^\circ\ 4'$. Cleavage: $1\text{-}\bar{\imath}$ very distinct.

H.=3·5. G.=4·338. Lustre vitreous, strong. Color honey-yellow, violet, the latter often external only. Streak white. Transparent. Plane of optical axes parallel to the base, and normal to $i\text{-}\breve{\imath}$; angle in oil for a plate of violet variety, normal to the obtuse bisectrix, 115° 50′ for the red rays; Descl.

Comp.—O. ratio for $\dot{R}$, $\ddot{\bar{A}}s$, $\dot{H}=4:5:1$; $\dot{Z}n^4\ddot{\bar{A}}s+\dot{Z}n\dot{H}$=Arsenic acid 40·2, oxyd of zinc 56·7, water 8·1=100. But the analysis gives $1\frac{1}{2}$ $\dot{H}$ instead of 1 $\dot{H}$. Analysis: Friedel (l. c.):

$\ddot{\bar{A}}s$ 39·95 $\dot{Z}n$ 54·32 $\dot{F}e$ 1·48 $\dot{M}n$ *tr.* $\dot{H}$ 4·55=100·30.

It is a zinc olivenite.

Pyr., etc.—Heated in a closed tube decrepitates feebly, and yields a little water, becoming white and porcelanous. On charcoal fuses, producing a coating of oxyd of zinc, and a feeble odor of arsenic. In a closed tube with soda and charcoal gives a ring of arsenic. With borax in O. F. pearl-yellow while hot, colorless on cooling. Easily soluble in dilute muriatic acid.

Obs.—From Chañarcillo, Chili, with limonite and native silver. Named after Mr. Adam of Paris.

538. CONICHALCITE. Konichalcit *Breith.* & Fritzsche, Pogg., lxxvii. 139, 1849.

Reniform and massive, resembling malachite.

H.=4·5. G.=4·123. Color pistachio-green, inclining to emerald-green; streak the same. Subtranslucent. Brittle. Fracture splintery.

Comp. - $(\dot{C}u, \dot{C}a)^4(\ddot{\bar{A}}s, \ddot{\bar{P}})+\dot{C}u\dot{H}+\frac{1}{2}\dot{H}$, with some vanadic acid replacing (?) part of the phosphoric, the copper and lime in equal proportions, the arsenic to the other acids as 2 : 1. Closely allied to olivenite and volborthite. Analysis by Fritzsche (l. c.):

$\ddot{\bar{A}}s$ 30·68 $\ddot{\bar{P}}$ 8·81 $\ddot{\bar{V}}$ 1·78 $\dot{C}u$ 31·76 $\dot{C}a$ 21·36 $\dot{H}$ 5·61.

Pyr., etc.—In the closed tube decrepitates, gives water, and turns black. In the forceps fuses, and colors the flame at first emerald-green, but after a time light blue adjacent to the assay. On charcoal fuses with deflagration to a red slag-like mass, which gives an alkaline reaction to test paper, and with soda gives a globule of copper. On charcoal, with salt of phosphorus and metallic lead, yields a glass which is dark yellow while hot and chrome-green on cooling (vanadium).

Obs.—From Hinajosa de Cordova, in Andalusia, Spain. Named from κονία, *lime*, and χαλκός.

539. BAYLDONITE. *A. H. Church*, J. Ch. Soc., II. iii. 265, 1865.

In minute mammillary concretions, with a drusy surface. Structure often somewhat reticulated.

H.=4·5. G.=5·35. Lustre strong resinous. Color grass-green to blackish-green. Streak siskin- to apple-green. Subtranslucent. Fracture subconchoidal, uneven.

Comp.—O. ratio for $\dot{\text{R}}$, $\ddot{\bar{\text{A}}}\text{s}$, $\dot{\bar{\text{H}}}$=4 : 5 : 2 nearly; whence $(\dot{\text{P}}\text{b}, \dot{\text{C}}\text{u})^4 \ddot{\bar{\text{A}}}\text{s} + 2\dot{\bar{\text{H}}}$, with $\dot{\text{P}}\text{b} : \dot{\text{C}}\text{u}$= 1 : 3; or $(\dot{\text{P}}\text{b}, \dot{\text{C}}\text{u})^3 \ddot{\bar{\text{A}}}\text{s} + \dot{\text{C}}\text{u}\dot{\bar{\text{H}}} + \dot{\bar{\text{H}}}$, Church,=Arsenic acid 31·6, oxyd of copper 32·8, oxyd of lead 30·7, water 4·9=100. Analysis: Church (l. c.):

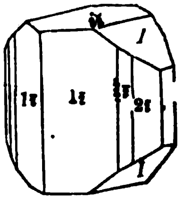
	$\ddot{\bar{\text{A}}}\text{s}$	$\dot{\text{C}}\text{u}$	$\dot{\text{P}}\text{b}$	$\dot{\bar{\text{H}}}$
(⅔)	31·76	30·88	30·13	4·58, $\ddot{\bar{\text{F}}}\text{e}$, $\dot{\text{C}}\text{a}$, and loss 2·65=100 Church.

Pyr., etc.—B.B. gives off water and becomes black, which latter reaction Church regards as indicating that part of the copper exists in the mineral as hydrate. On charcoal fuses to a black bead, deflagrates, giving off arsenical fumes, and leaves a white metallic bead of lead and copper. With borax in outer flame gives a blue bead. Difficultly soluble in nitric acid.

Obs.—Occurs in Cornwall. Named after Dr. John Bayldon.

540. EUCHROITE. Euchroit *Breith.*, Char., 172, 266, 1823.

469



Orthorhombic. $I \wedge I$=92° 8′, $O \wedge$ 1-ī=148° 40′; $a : b : c$=0·6088 : 1 : 1·038. Observed planes as in the annexed figure. 1-ī ∧ 1-ī=117° 20′, *i*-ī ∧ 1-ī=121° 20′, *i*-ī ∧ ⅔-ī=132° 24′, *i*-ī ∧ 2-ī=140° 36½′, 2-ī ∧ 2-ī, ov. *i*-ī, =101° 13′. Cleavage: *I* and 1-ī. Faces 1-ī vertically striated.

H.=3·5—4. G.=3·389. Lustre vitreous. Color bright emerald- or leek-green. Transparent—translucent. Fracture small conchoidal—uneven. Rather brittle.

Comp.—$\dot{\text{C}}\text{u}^4 \ddot{\bar{\text{A}}}\text{s} + 7\dot{\bar{\text{H}}}$, or $\dot{\text{C}}\text{u}^3 \ddot{\bar{\text{A}}}\text{s} + \dot{\text{C}}\text{u}\dot{\bar{\text{H}}} + 6\dot{\bar{\text{H}}}$ (Ramm.)=Arsenic acid 34·1, oxyd of copper 47·2, water 18·7=100. Analyses: 1, Turner (Edinb. Phil. J., iv. 301); 2, 3, Kühn (Ann. Ch Pharm., li. 128); 4, Wöhler (ib., 285):

	$\ddot{\bar{\text{A}}}\text{s}$	$\dot{\text{C}}\text{u}$	$\dot{\bar{\text{H}}}$
1. Libethen	33·02	47·85	18·80=99·67 Turner.
2. "	34·42	46·97	19·31=100·70 Kühn.
3. "	32·42	46·99	19·31, $\dot{\text{C}}\text{a}$ 1·12=99·84 Kühn.
4. "	33·22	48·09	18·39=99·70 Wöhler.

Pyr., etc.—In the closed tube gives more water, but has otherwise the same reactions as olivenite.

Obs.—Occurs in quartzose mica slate at Libethen in Hungary, in crystals of considerable size, having much resemblance to dioptase.

Named from εὐχροα, *beautiful color.*

If the prism 2-ī were made the fundamental vertical prism in euchroite, then $I \wedge I$ would equa. 101° 13′, and 1-ī ∧ 1-ī, top,=87° 52′, nearly as in wolfram and hopeite. The cleavage is not in accordance with this view.

Alt.—Tschermak suggests that olivenite may be euchroite altered by the loss of water, he finding crystals of olivenite projecting from the holes of cavernous euchroite (Ber. Ak. Wien, li. 129).

541. TAGILITE. Tagilith (fr. N. Tagilsk) *Hermann*, J. pr. Ch., xxxvii. 184, 1846; (fr. Ullersreuth) *Breith.*, B. H. Ztg., xxiv. 309.

Monoclinic, but like liroconite in habit of crystals, Breith. Cleavage: brachydiagonal, distinct. Also in reniform or spheroidal concretions. Structure fibrous; also earthy.

H.=3—4. G.=about 3·5, Hermann; 4·076, Breith. Lustre vitreous

Color verdigris- to emerald-green. Streak verdigris-green. Subtranslucent. Brittle.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$, $\dot{\mathrm{H}}$=4 : 5 : 3; whence $\dot{\mathrm{C}}\mathrm{u}^4\,\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+3\,\dot{\mathrm{H}}$; or, $\dot{\mathrm{C}}\mathrm{u}^3\,\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+\dot{\mathrm{C}}\mathrm{u}\,\dot{\mathrm{H}}+2\,\dot{\mathrm{H}}$ (Ramm.)=Phosphoric acid 27·7, oxyd of copper 61·8, water 10·5=100. Analyses: 1, 2, Hermann (l. c.); 3, Field (Ch. Gaz., June 15, 1859):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{H}}$
1. Ural	26·44	61·29	10·77, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}$ 1·50=100 Hermann.
2. "	26·91	62·58	10·71=100 Hermann.
3. Coquimbo	27·42	61·70	10·25=99·37 Field.

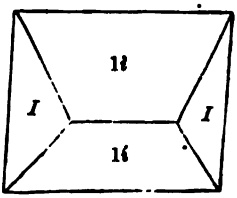
Pyr., etc.—No blowpipe characters are given by Hermann.

Obs.—Occurs at Nischne Tagilsk on limonite; at the Arme Hilfe mine, Ullersreuth, in minute crystals and reniform groups or masses, on limonite, with quartz; in S. America, at the Mercedes mine, Coquimbo, fibrous, on limonite.

Hermann's *tagilite* was in reniform concretions, with H.=3, G.=3·5, and color emerald- to mountain-green; and had the composition mentioned. The other characters in the above description (excepting the anal. by Field) are from Breithaupt, in an account of the Ullersreuth ore, which he refers to tagilite, but which has not been analyzed, and may or may not be that species.

542. LIROCONITE. Octahedral Arseniate of Copper (fr. Cornwall) *Bourn.*, Phil. Trans., 1801 174, Rashleigh's Brit. Min., ii., pl. 2, 5, 11, 1802. Linsenerz *Wern.*, 1803, Ludwig's Min., ii. 215, 1804; *Karsten*, Tab., 64, 1808. Linsenkupfer *Hausm.*, Handb., 1051, 1813. Lirokonmalachit pt. *Mohs*, Grundr., 180, 1822. Chalcophacit *Glocker*, Handb., 859, 1831.

470



Monoclinic, Breith., Descl. $I \wedge I=74°\ 21'$, Descl.; 72° 22′, B. & M.; 71° 59′, Breith. $1\text{-}\grave{\imath} \wedge 1\text{-}\grave{\imath}=61°\ 31'$, Descl.; 60° 40′, B. & M. $C=88°\ 33'$. Observed planes as in the annexed figure. Cleavage lateral, but obtained with difficulty. Rarely granular.

H.=2–2·5. G.=2·882, Bournon; 2·926, Haid.; 2·985, Hermann; 2·964, Damour. Lustre vitreous, inclining to resinous. Color and streak sky-blue—verdigris-green. Fracture imperfectly conchoidal, uneven. Imperfectly sectile.

Comp.—O. ratio fr. anal. 1, 3, 4, for $\dot{\mathrm{R}}$, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{l}$, ($\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$), $\dot{\mathrm{H}}$=4 : 2 : 5 : 12; whence $\dot{\mathrm{C}}\mathrm{u}^3\,(\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s},\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}})+(\tfrac{1}{3}\,\dot{\mathrm{C}}\mathrm{u}^3+\tfrac{2}{3}\,\overset{\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{l})\,\dot{\mathrm{H}}^3+9\,\dot{\mathrm{H}}$, if the alumina and a fourth of the copper may be in the state of hydrate. It is closely parallel with that of pseudomalachite, the second member corresponding in oxygen to $\dot{\mathrm{C}}\mathrm{u}^3\,\dot{\mathrm{H}}^3$, or $3\,\dot{\mathrm{C}}\mathrm{u}\,\dot{\mathrm{H}}$. As the O. ratio for bases and acid is 6 : 5, the formula might be written $(\tfrac{2}{3}\,\dot{\mathrm{C}}\mathrm{u}^3+\tfrac{1}{3}\,\overset{\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{l})^2\,(\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s},\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}})+12\,\dot{\mathrm{H}}$. Analyses: 1, T. Wachtmeister (Ak. H. Stockh., 80, 1832); 2, Hermann (J. pr. Ch., xxxiii. 296); 3, 4, Damour (Ann. Ch. Phys., III. xiii. 404):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\overset{\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{H}}$
1. Cornwall	20·79	3·61	8·03	35·19	22·24, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}$ 3·41, $\overset{\cdot\cdot\cdot}{\mathrm{S}}\mathrm{i}$ 4·04, gangue 2·95=100·26 W.
2. "	23·05	3·73	10·85	36·38	25·01, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}$ 0·98=100 Hermann.
3. "	22·22	3·49	9·68	37·18	25·49=98·06 Damour.
4. "	23·40	3·24	10·09	37·40	25·44=98·47 Damour.

Pyr., etc.—In the closed tube gives much water and turns olive-green. B.B. cracks open, but does not decrepitate; fuses less readily than olivenite to a dark gray slag; on charcoal cracks open, deflagrates, and gives reactions like olivenite. Soluble in nitric acid.

Obs.—Crystals occasionally an inch in diameter; usually quite small. With various ores of copper, pyrite, and quartz, at Wheal Gorland, Wheal Muttrell, and Wheal Unity, in Cornwall; also in minute crystals at Herrengrund in Hungary; and in Voigtland.

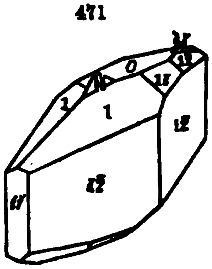
The prism *i*-2 (which may be taken as *I*) has the front angle 111° 17′, if calculated from $I \wedge I=72°\ 22'$, and this is near the angle $I \wedge I$ of pseudomalachite. Moreover, the formulas of the two are similar, as shown above.

Named from λειρός, *pale*, and κονία, *powder*.

543. PSEUDOMALACHITE. Phosphorsaures Kupfer pt. *Karst.*, *Klapr.*, N. Schrift. Berl. Ges. Nat., Fr. iii. 304, 1801. Phosphorkupfer *id.*, Tab., 64, 97, 1808. Phosphorkupfererz *Wern.* Cuivre phosphaté *H.*, Tabl., 92, 1809. Phosphate of Copper. Pseudomalachit *Hausm.*, Handb., 1035, 1813. Phosphorochalcit *Glocker*, Handb., 847, 1831. Ypoléime *Beud.*, Tr., ii. 570, 1832. Ehlit, Prasin-chalzit, *Breith.* Char., 45, 49, 1832. Lunnit *Bernhardi.* Kupferdiaspore *Kühn*, J. Ch. Pharm., li. 125, 1844. Dihydrit *Herm.*, J. pr. Ch., xxxvii. 178, 1846.

Orthorhombic, hemihedral (monoclinic?). $I \wedge I=109°\ 28'$, $O \wedge 1\text{-}\bar{i}=146°\ 18\tfrac{1}{2}'$; $a:b:c=\sqrt{2}:1:0{\cdot}6667$. Observed planes as in the annexed figure. $i\text{-}2 \wedge i\text{-}2=141°\ 4'$ and $38°\ 56'$, $1 \wedge 1=117°\ 49'$, $O \wedge \tfrac{1}{2}\text{-}\bar{i}=166°\ 34'$, $1\text{-}\bar{i} \wedge 1\text{-}2=168°\ 46'$. Cleavage: $i\text{-}\bar{i}$ imperfect. Also reniform or massive; indistinctly fibrous, and having a drusy surface.

471



H.=4·5—5. G.=4—4·4. Lustre adamantine, inclining to vitreous. Color dark emerald-, verdigris-, or blackish-green, often darker at the surface. Streak green, a little paler than the color. Translucent—subtranslucent. Fracture small conchoidal—uneven. Brittle.

Var., Comp.—The analyses vary much, and have been regarded by Hermann and others as indicating that two or three species are here included; but the differences may be only a consequence of mixture. The supposed species distinguished are as follows:

A. *Ehlite* (and Prasin) of Breithaupt. Formula $\dot{\mathrm{C}}\mathrm{u}^6\ddot{\bar{\mathrm{P}}}+3\dot{\mathrm{H}}$, or $\dot{\mathrm{C}}\mathrm{u}^3\ddot{\bar{\mathrm{P}}}+2\dot{\mathrm{C}}\mathrm{u}\,\dot{\mathrm{H}}+\dot{\mathrm{H}}$ (Ramm), = Phosphoric acid 23·9, oxyd of copper 67·0, water 9·1=100. Occurs crystallized; also reniform and botryoidal, with a radiating fibrous structure; also massive. G.=3·8—4·4. Includes analyses 1—7, and perhaps others.

The name *Prasin* is used by Breithaupt for pseudomalachite in general; he cites Berthier's analysis (No. 3) of a Libethen ore, and one by Lunn (p. 569) of a Rheinbreitenbach specimen, and mentions other localities in Bavaria, Voigtland, and Siberia. For his *ehlite* he gives Bergemann's analysis of an Ehl specimen (No. 5) which does not differ essentially from Berthier's. According to a recent analysis of the Ehl mineral by Bergemann (No. 6), it contains 7 p. c. of *vanadic* acid replacing part of the phosphoric.

B. *Dihydrite.* Formula $\dot{\mathrm{C}}\mathrm{u}^6\ddot{\bar{\mathrm{P}}}+2\dot{\mathrm{H}}$, or $\dot{\mathrm{C}}\mathrm{u}^3\ddot{\bar{\mathrm{P}}}+2\dot{\mathrm{C}}\mathrm{u}\,\dot{\mathrm{H}}$ (Ramm), = Phosphoric acid 24·7, oxyd of copper 69·0, water 6·3=100. Includes the analyses having 6 to 6·5 p. c. of water.

C. *Pseudomalachite.* Formula $\dot{\mathrm{C}}\mathrm{u}^6\ddot{\bar{\mathrm{P}}}+3\dot{\mathrm{H}}$, or $\dot{\mathrm{C}}\mathrm{u}^3\ddot{\bar{\mathrm{P}}}+3\dot{\mathrm{C}}\mathrm{u}\,\dot{\mathrm{H}}$ (Ramm), = Phosphoric acid 21·1, oxyd of copper 70·9, water 8·0=100. Includes analyses 16–19.

Nordenskiöld unites *Dihydrite* and *Ehlite.*

Analyses: 1, Hermann (J. pr. Ch., xxxvii); 2, Kühn (Ann. Ch. Pharm., xxxiv. 218); 3, Berthier (Ann. d. M., viii.); 4, Nordenskiöld (l. c.); 5, Bergemann (Schw. J., liv. 305); 6, Bergemann (Jahrb. Min. 1858, 195); 7, Heddle (Phil. Mag., IV. x. 39); 8, 9, Hermann (l. c.); 10–13, Nordenskiöld (l. c.); 14, Arfvedson (Jahresb., iv. 143); 15, Kühn (l. c., lv. 124); 16, 17, Kühn (l. c.) 18, Rhodius (Pogg., lxii. 369); 19, Church (Ch. News, x. 217); 20, Bergemann (Pogg., civ. 190):

20. Lins	19·89	69·97	8·21, $\ddot{\bar{\text{A}}}\text{s}$ 1·78=99·85 Bergemann.

Rev. F. Lunn obtained for an ore from Rheinbreitenbach (Ed. Phil. J., v. 211, 1821) $\ddot{\bar{\text{P}}}$ 21·687, $\dot{\text{Cu}}$ 62·847, $\dot{\text{H}}$ 15·454=99·988, giving the formula $\dot{\text{Cu}}^5\ddot{\bar{\text{P}}}^2+5\,\dot{\text{H}}$. But no later analyst has found as much water. Beudant cites this analysis under his *ypoleime*.

Pyr., etc.—Like libethenite; some varieties decrepitate remarkably and yield a black powder in the closed tube.

Obs.—Occurs in veins traversing slate at Virneberg, near Rheinbreitenbach, and at Ehl, near Lins, on the Rhine, along with other copper ores; at Hirschberg in Voigtland; Libethen in Hungary; Nischne Tagilsk in Siberia. Found in Cornwall, consisting of minute globular concretions. Also met with in the Perkiomen mine, Pa.; in Cabarras Co., N. C.

The phosphates of copper were included in the oliveners and malachite of the mineralogists of last century.

Pseudomalachite of Hausmann is the earliest of the names of this species, and is as short and as good as the later *Phosphorochalcite* of Glocker. *Lunnite* was substituted by Bernhardi, and has been used in some recent works. But Lunn's one analysis was not made until 1821, and gives a different composition from that since obtained. It will certainly be soon enough to use his name in mineralogy when a mineral having the composition he arrived at, and thus befitting it, has been identified.

544. ERINITE. *Haid.*, Ann. Phil., II. iv. 154, 1828.

In mammillated crystalline groups, concentric in structure and fibrous, and rough from the terminations of very minute crystals; the concentric layers compact, and often easily separable. Traces of cleavage in one direction.

H.=4·5—5. G.=4·043. Lustre almost dull, slightly resinous. Color fine emerald-green, slightly inclining to grass-green. Streak green, paler than the color. Subtranslucent—nearly opaque. Brittle.

Comp.—$\dot{\text{Cu}}^5\ddot{\bar{\text{A}}}\text{s}+2\,\dot{\text{H}}$, or $\dot{\text{Cu}}^3\ddot{\bar{\text{A}}}\text{s}+2\,\dot{\text{Cu}}\,\dot{\text{H}}$ (Ramm.),=Arsenic acid 34·7, oxyd of copper 59·9, water 5·4=100. Analysis (approximative) by Turner (l. c.):

$\ddot{\bar{\text{A}}}\text{s}$ 33·78 $\dot{\text{Cu}}$ 59·44 $\dot{\text{H}}$ 5·01 $\dddot{\bar{\text{A}}}\text{l}$ 1·77=100.

Pyr., etc.—In the closed tube decrepitates and yields water. B.B. on charcoal emits arsenical fumes and fuses, giving an arsenid, which in O.F. yields a globule of copper. Soluble in nitric acid.

Obs.—Stated by Haidinger to come from the County of Limerick, Ireland; but shown by Church to be a Cornish species.

545. CORNWALLITE. Cornwallit *Zippe*, Abh. d. Böhm. Ges. Prag, 1846.

Amorphous.

H.=4·5. G.=4·160. Color emerald-green to dark verdigris-green. Fracture conchoidal.

Comp.—$\dot{\text{Cu}}^5\ddot{\bar{\text{A}}}\text{s}+5\,\dot{\text{H}}$, or $\dot{\text{Cu}}^3\ddot{\bar{\text{A}}}\text{s}+2\,\dot{\text{Cu}}\,\dot{\text{H}}+3\,\dot{\text{H}}$ (Ramm.). According to Lerch, who obtained, as a mean of two analyses (l. c., Ramm. Min. Ch., 377):

$\ddot{\bar{\text{A}}}\text{s}$ 30·22 $\ddot{\bar{\text{P}}}$ 2·15 $\dot{\text{Cu}}$ 54·55 $\dot{\text{H}}$ 13·02=99·94.

Pyr., etc.—In the matrass yields water. B.B. on charcoal gives arsenical fumes, and a bead of copper enveloped in a brittle crust.

Obs.—From Cornwall, occurring in small botryoidal or disseminated individuals on olivenite. Resembles malachite, but differs from it in not effervescing with acids.

546. TYROLITE. Kupferschaum *Wern.*, Hoffm. Min., iii. 180, 1816, Letzt. Min. Syst., 19, 50, 1817. Kupaphrite *Shep.*, Min., i. 294, 1835. Tirolit *Haid.*, Handb., 509, 1845.

Orthorhombic. Observed planes: *O*, *i-ĭ*, *I*. Cleavage: *O*, perfect. Usually reniform, massive; structure radiate foliaceous, surface drusy.

H.=1—2. G.=3·02—3·098. Lustre: *O* pearly; other faces vitreous. Color pale apple-green and verdigris-green, inclining to sky-blue. Streak a little paler. Translucent—subtranslucent. Fracture not observable. Very sectile. Thin laminæ flexible.

Comp.—$\dot{C}u^5\ddot{\bar{A}}s+9\dot{H}$, or $\dot{C}u^3\ddot{\bar{A}}s+2\dot{C}u\dot{H}+7\dot{H}$ (Ramm.),=Arsenic acid 29·2, oxyd of copper 50·3, water 20·5=100, with carbonate of lime as impurity. Analysis: v. Kobell (Pogg., xviii. 253):

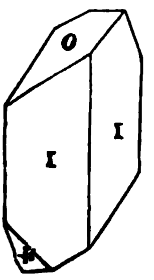
Falkenstein, Tyrol $\ddot{\bar{A}}s$ 25·01 $\dot{C}u$ 43·88 $\dot{H}$ 17·46 $\dot{C}a\ddot{C}$ 13·65=100.

Pyr., etc.—In the closed tube decrepitates and yields much water. B.B. in the forceps fuses to a steel-gray globule. On charcoal gives off arsenical fumes, and fuses quietly without deflagration to a slaggy mass, which in R.F. yields globules of copper. Soluble in nitric acid with effervescence. Soluble in ammonia, yielding a blue solution and a white residue of carbonate of lime.

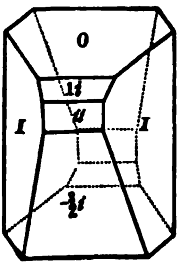
Obs.—Usually occurs in the cavities of calamine, calcite, or quartz, accompanied by other ores of copper, appearing in small aggregated and diverging fibrous groups of a pale green color, and possessing a delicate silky lustre. Has been observed in the Bannat; at Posing and Libethen in Hungary; Nertschinsk in Siberia; Falkenstein and Schwatz in the Tyrol; Saalfeld in Thuringia; Riechelsdorf in Hessia; Schneeberg in the Erzgebirge; in zechstein-dolomite near Bieber.

547. CLINOCLASITE. Strahliges Olivenerz *Karst.*, Klapr., N. Schrift. Berl. Ges. Fr., iii. 298, 1801. Cupreous Arsenate of Iron *Bourn.*, Phil. Trans., 1801 (with anal. by Chenevix). Strahlenerz *Karsten*, Tab., 64, 97, 1808. Cuivre arseniaté férrifère *H.*, Tabl., 91, 1809. Strahlenkupfer *Hausm.*, Handb., 1050, 1813. Strahlerz *Wern.* Klinoklas *Breith.*, Uib., 1830. Siderochalcit *Glocker*, Grundr., 840, 1831. Aphanèse *Beud.*, Tr., ii. 602, 1832. Aphanesite *Shep.*, Min., 1835. Abichit *Bernhardi*, Glocker's Grundr., 579, 1839.

472



473



Monoclinic. *C*=80° 30′, *I* ∧ *I*, front,=56°, side, 124°. Observed planes as in the annexed figures. $O \wedge -\frac{1}{2}i$=99° 30′, $O \wedge 1\text{-}i$=123° 48′. Cleavage: basal, highly perfect. Also massive, hemispherical, or reniform; structure radiated fibrous.

H.=2·5—3. G.=4·19—4·36. Lustre: *O* pearly; elsewhere vitreous to resinous. Color internally dark verdigris-green; externally blackish-blue green. Streak bluish-green. Subtranslucent. Not very brittle.

Comp.—$\dot{C}u^6\ddot{\bar{A}}s+8\dot{H}$, or $\dot{C}u^3\ddot{\bar{A}}s+3\dot{C}u\dot{H}$ (Ramm.),=Arsenic acid 30·2, oxyd of copper 62·7, water 7·1=100. Analyses: 1, Rammelsberg (2d Suppl., 78); 2, Damour (Ann. Ch. Phys., III xiii.):

			$\ddot{\bar{A}}s$	$\ddot{\bar{P}}$	$\dot{C}u$	$\dot{H}$	$\ddot{\bar{F}}e$
1	Cornwall	G.=4·258—4·359	29·71	0·64	60·00	7·64	0·89, $\dot{C}a$ 0·50, $\dddot{S}i$ 1·12=100 Ramm
2.	"	G.=4·312	27·09	1·50	62·80	7·57	0·49=99·44 Damour.

Pyr., etc.—Same as for olivenite.

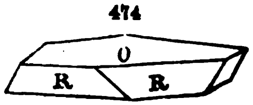
Obs.—Occurs in Cornwall, with other ores of copper, at Ting Tang mine, Wheal Unity, and Wheal Gorland, and at Bedford United Mines, near Tavistock. The crystals usually present a very dark blue color and brilliant lustre, but are rarely recognizable, being aggregated in diverging groups. or disposed in extremely minute individuals, in cavites of quartz; whence the name *aphanesite*, from 'αφανής, *unmanifest*. Also found in the Erzgebirge.

Named *Clinoclasite* in allusion to the basal cleavage being oblique to the sides of the prism.

548. CHALCOPHYLLITE. Cuivre arseniaté lamelliforme *H.*, Tr., 1801; *Vauquelin*, J. d. M., x. 562, 1801. Blättriges Olivenerz, Kupferglimmer, *Karst.*, Hoff's Mag., i. 543, 1801; Ludwig's Werner, 180, 1803. Copper Mica *Jameson*, Min., 1820. Kupferphyllit *Breith.*, Char., 42, 1832. Chalkophyllit *Breith.*, Handb., 149, 1847. Tamarite *B. & M.*, Min., 1852.

Rhombohedral. $R \wedge R = 69° 48'$, $O \wedge R = 108° 44'$; $a = 2{\cdot}5536$. Observed planes: R, 2, O, $-\frac{1}{4}$, I. $\frac{1}{4} \wedge \frac{1}{4} = 88° 46'$, $O \wedge \frac{1}{4} = 124° 9'$. Usually in six-sided tabular crystals; plane O sometimes triangularly striated. Cleavage: O highly perfect. Also foliated massive, and in druses.

474



H.=2. G.=2·4—2·66; 2·435, Cornwall, Hermann; 2·659, ib., Damour. Lustre: of O pearly; of other faces vitreous or subadamantine. Color emerald- or grass-green to verdigris-green. Streak somewhat paler than the color. Transparent—translucent. Fracture scarcely observable.

Comp.—$\dot{\text{Cu}}^8 \ddot{\bar{\text{As}}} + 12 \dot{\text{H}}$, or $\dot{\text{Cu}}^8 \ddot{\bar{\text{As}}} + 5 \dot{\text{Cu}} \dot{\text{H}} + 7 \dot{\text{H}}$, from Chenevix's analysis, = Arsenic acid 21·3, oxyd of copper 58·7, water 20·0=100. From Hermann's analysis, $\dot{\text{Cu}}^8 \ddot{\bar{\text{As}}} + 23 \dot{\text{H}}$ = Arsenic acid 18·0, oxyd of copper 49·6, water 32·4=100. Analyses: 1, Chenevix (Phil. Trans., 1801); 2, Hermann (J. pr. Ch., xxxiii. 294); 3, 4, Damour (Ann. Ch., Phys., III. xiii. 404):

			$\ddot{\bar{\text{As}}}$	$\dot{\text{Cu}}$	$\dot{\text{H}}$
1.	Cornwall		21	58	21=100 Chenevix.
2.	"	G.=2·435	17·51	44·45	31·19, $\dot{\text{Fe}}$ 2·92, $\ddot{\bar{\text{Al}}}$ and $\ddot{\bar{\text{P}}}$ 3·93=100 Hermann.
3.	"	G.=2·659	19·85	52·92	23·94, $\ddot{\bar{\text{Al}}}$ 1·80, $\ddot{\bar{\text{P}}}$ 1·29=99·30 Damour.
4.	"	"	21·27	52·30	22·58, $\ddot{\bar{\text{Al}}}$ 2·13, $\ddot{\bar{\text{P}}}$ 1·56=99·84 Damour.

Pyr., etc.—In the closed tube decrepitates, yields much water, and gives a residue of olive-green scales. In other respects like olivenite. Soluble in nitric acid, and in ammonia.

Obs.—The copper mines of Tingtang, Wheal Gorland, and Wheal Unity, near Redruth, are its principal localities in Cornwall. Occurs also crystallized in iron ore at Sayda in Saxony; in minute crystals at Herrengrund in Hungary; Moldawa in the Bannat.

Taking $\frac{1}{4} R$ as the fundamental rhombohedron, then $R \wedge R = 88° 46'$, and $a = 1{\cdot}7768$.

Alt.—Found altered to chrysocolla.

---

549. BERLINITE. Berlinit *C. W. Blomstrand*, Priv. contrib., dated Lund, Dec. 9, 1867.

Compact massive, without a trace of cleavage.

H.=6. G.=2·64. Lustre vitreous. Colorless to grayish or pale rose-red. Streak uncolored. Translucent. Fracture uneven.

Comp.—$\ddot{\bar{\text{Al}}}\ \ddot{\bar{\text{P}}} + \frac{1}{2} \dot{\text{H}}$, Blomstrand, = Phosphoric acid 55·9, alumina 40·5, water 3·6 = 100. Analysis: C. W. Blomstrand (l. c.):

$\ddot{\bar{\text{P}}}$ ($\frac{3}{4}$) 54·84 $\ddot{\bar{\text{Al}}}$ 40·27 $\ddot{\bar{\text{Fe}}}$ 0·26 $\dot{\text{H}}$ 4·14=99·51.

Pyr., etc.—B.B. whitens without fusing. A deep blue color with cobalt. Hardly attacked by acids. Easily decomposed on fusion with alkalies, and the resulting mass soluble in water with evolution of much heat.

Obs.—Resembles quartz. From the iron mine of Westana in Scania, Sweden, where it occurs sparingly in quartz, from which it is ordinarily separated by a thin layer of lazulite.

Named after Prof. N. H. Berlin, of the University of Lund.

550. CALLAINITE. ? Callaina *Plin.*, xxxvii. 33. Turquois pt. Callais *Damour*, C. R., lix 936, 1864. Callainite *Dana.*

Massive. Texture wax-like.

H.=3·5–4. G.=2·50–2·52. Color apple-green to emerald-green, spotted or lined with whitish and bluish. Translucent.

Comp.—$\bar{\text{A}}\text{l}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+5\dot{\text{H}}$=Phosphoric acid 42·39, alumina 30·75, water 26·86=100. **Analysis:** A. Damour (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$	$\bar{\text{A}}\text{l}$	$\bar{\text{F}}\text{e}$	$\dot{\text{M}}\text{n}$	$\dot{\text{C}}\text{a}$	$\dot{\text{H}}$	Sand
42·58	29·57	1·82	*tr.*	0·70	23·62	2·10=100·39.

Pyr., etc.—When heated yields water, and becomes opaque, chocolate-brown, and friable B.B. infusible.

Obs.—From a Celtic grave, near Mané-er H'roek in Lockmariaquer, in rounded pieces from the size of a flax-seed to that of a pigeon's egg, and found in the collections of the Polymathic Society of Morbihan, in western France.

Damour makes this mineral the *callais* of Pliny, and especially in view of its *green* color. But the callais was blue, and the green stone really related to it was probably the *callaina* (see p 581). Yet, as this identity is not established, the name *callainite* is better than Pliny's name unmodified.

551. LAZULITE. Himmelblau Fossil von Steiermark [Styria] *Widenmann*, Bergm. J., 345, Ap. 1791; Smalteblaue F. von Vorau, Schrift. Ges. N. Rammelsberg found some silica, as impurity, in his analyses, which is excluded in the results above given.

Pyr., etc.—In the closed tube whitens and yields water. B.B. with cobalt solution the blue color of the mineral is restored. In the forceps whitens, cracks open, swells up, and without fusion falls to pieces, coloring the flame bluish-green. The green color is made more intense by moistening the assay with sulphuric acid. With the fluxes gives an iron glass; with soda on charcoal an infusible mass. Unacted upon by acids, retaining perfectly its blue color.

Obs.—Occurs both massive and crystallized in narrow veins, traversing clay slate, in the torrent beds of Schladming and Rädelgraben, near Werfen in Salzburg, with spathic iron; in Gratz, near Vorau; in Krieglach, in Styria; at Hochthäligrat, at the Gorner glacier, Rympfischwang, Upper Valais, in Switzerland, H.=about 4; also in veins or pockets in quartzite, in Horrsjöberg Wermland, massive and granular, sometimes in 8-sided crystals 6 inches long and 2 inches in diameter; in the iron mine of Westana, in Scania, Sweden, massive, of a dark azure color, also at Tijuco in Minas Geraes, Brazil. Abundant at Crowder's Mt., Lincoln Co., N. C.; and in fine sky-blue crystals, often 1—1½ inch long and broad, on Graves Mt., Lincoln Co., Ga., 50 m above Augusta, with cyanite, rutile, pyrophyllite, etc.

The name lazulite is derived from an Arabic word, *azul*, meaning *heaven*, and alludes to the color of the mineral.

On cryst., Prüfer, Nat. Abhandl. Wien, i. 169; Dana, Am. J. Sci., II. xxvii. 38

552. BARRANDITE. Barrandit *v. Zepharovich*, Ber. Ak. Wien, lvi. 1867.

In spheroidal concretions, indistinctly radiated fibrous, with the surface crystalline angular; concentric in structure.

H.=4·5. G.=2·576. Lustre between vitreous and greasy. Color pale-bluish, reddish, greenish or yellowish-gray. Streak yellowish to bluish-white. Translucent to opaque.

Comp.—O. ratio for $\overline{\text{R}}, \ddot{\text{P}}, \dot{\text{H}}$=3 : 5 : 4, with $\overline{\text{R}}=\frac{4}{7}\,\overline{\text{Fe}}+\frac{3}{7}\,\overline{\text{Al}}$; whence $(\frac{4}{7}\,\overline{\text{Fe}}+\frac{3}{7}\,\overline{\text{Al}})\ddot{\text{P}}+4\,\dot{\text{H}}$= Phosphoric acid 40·63, alumina 12·61, sesquioxyd of iron 26·16, water 20·60=100. **Analysis:** E. Boricky (l. c.):

$\ddot{\text{P}}$	$\overline{\text{Al}}$	$\overline{\text{Fe}}$	$\dot{\text{H}}$
39·68	12·74	26·58	21·00=100.

Pyr., etc.—Yields water with an acid reaction. B.B. splits open and becomes darker in color; moistened with sulphuric acid colors the flame bluish-green. Soluble in hot muriatic acid.

Obs.—Occurs at Cerhovic, N.N.W. of Przibram, in Bohemia, in clefts in a Lower Silurian sandstone, with cacoxene and stilpnosiderite; the translucent globules ½ to 1½ mm. in diameter, and having within some resemblance to opal; the opaque variety without lustre; sometimes a grain of limonite at centre, and particles of the same as impurity.

Alt.—Stated to give origin by alteration to dufrenite, similar globules and fibrous crusts at the locality having the composition of the latter mineral.

---

553. SCORODITE. Cupreous Arseniate of Iron. Cupro-martial Arsenate *Bourn.*, Phil. Trans., 1801, 191. Martial Arseniate of Copper. Cuivre arseniaté ferrifère *H.*, Tabl., 91, 1809. An *Iron-sinter* (Eisensinter, Arsenik-sinter), from Nertschinsk, analyzed by Hermann, is an amorphous scorodite. Hermann obtained (J. pr. Ch., xxxiii. 95) $\ddot{\bar{A}}s$ 48·05, $\ddot{\bar{F}}e$ 36·41, $\dot{H}$ 15·54=100.

Pyr., etc.—In the closed tube yields neutral water and turns yellow. B.B. fuses easily, coloring the flame blue. B.B. on charcoal gives arsenical fumes, and with soda a black magnetic scoria. With the fluxes reacts for iron. Soluble in muriatic acid.

Obs.—Found of brown color in the granitic mountains of Schwarzenberg in Saxony, associated with arsenopyrite; at Löling, near Huttenberg in Carinthia, with leucopyrite; at Chanteloube, near Limoges; at Nertschinsk, Siberia, in fine crystals; also as an amorphous crust or *iron-sinter* on beryl, topaz, and quartz; leek-green, in the Cornish mines, coating cavities of ferruginous quartz; at the Minas Goraes, in Brazil; in Popayan; at the gold mines of Victoria in Australia, in quartz with arsenopyrite and gold.

Occurs in minute crystals and druses of leek-green and greenish-white colors, near Edenville, N. Y., with arsenopyrite, iron-sinter, etc., in white limestone; in Cabarras Co., N. C., on G. Luderick's farm, in aggregations of greenish-white, brownish- and leek-green crystals; coating cavities of quartz and limonite with copper ores and pyrite.

The cobalt-scorodite of Lippmann (l. c.) occurs in bluish crystals with quartz and hypochlorite, at Schneeberg; it has not been analyzed.

Named from σκόροδον, *garlic*, alluding to the odor before the blowpipe.

Alt.—Scorodite occurs altered to limonite.

554. WAVELLITE. Wavellite *Babbington*, Davy's Mem. in Phil. Tr., 162, 1805. Hydrargillite *Davy*, ib., 155, 162. Devonite *Thomson*. * With peroxyd of manganese.

Hermann obtained much less fluorine than Berzelius, and gives a different formula. But Berzelius remarks that this ingredient may easily fall short.

The cement of a conglomerate near Loughhill, Co. of Limerick, Ireland, consisting of emerald green, with some white, crystals, approaches wavellite in composition, affording A. Gages (J. G Soc. Dubl., viii. 73) $\ddot{\bar{P}}$ 30·88, $\ddot{\bar{A}}l$ 36·16, $\ddot{\bar{F}}e$ 1·81, $\dot{N}i$ 0·33, $\dot{H}$ 23·56, F *tr.*, $\ddot{S}i$ 3·61, apatite 1·58, quartz 1·00=98·94. A wavellite containing oxyd of lead occurs at Rosières in stalactites, as detected by Berthier.

Pyr., etc.—In the closed tube gives off much water, the last portions of which react acid and color Brazil-wood paper yellow (fluorine), and also etch the tube. B.B. in the forceps swells up and splits frequently into fine acicular particles, which are infusible, but color the flame pale green; moistened with sulphuric acid the green becomes more intense. Gives a blue with cobalt solution. Some varieties react for iron and manganese with the fluxes. Heated with sulphuric acid gives off fumes of fluohydric acid, which etch glass. Soluble in muriatic acid, and also in caustic potash.

Obs.—Wavellite was first discovered in a tender clay slate near Barnstaple, in Devonshire, by Dr. Wavel. It has since been found at Clonmel and Cork, Ireland; in the Shaint Isles of Scotland; at Zbirow in Bohemia; Zajecov in Bohemia; at Frankenberg and Langenstriegis, Saxony; Diensberg near Giessen, Hesse Darmstadt; on brown iron ore in the Jura limestone at Amberg in Bavaria (the *lasionite* of Fuchs); in a manganese mine at Weinbach near Weilburg in Nassau (Genth); at Villa Rica, Minas Geraes, Brazil.

In the United States reported as found near Saxton's River, Bellows Falls, N. H.; also at the slate quarries of York Co., Pa., near the Susquehanna; at Washington mine, Davidson Co., N. C., with actinolite, pyrite, and native silver; at Steamboat, Chester Co., Pa., in a bed of limonite, abundant in stalactitic forms, part looking like gibbsite, part drusy with rhombic crystals, and often coated with a pearly scaly mineral yet undetermined.

Named after Dr. Wavel, the discoverer. The species was considered a variety of diaspore by D'Aubuisson, Bournon, Hausmann, and some other early mineralogists, and placed next to diaspore by Werner in 1817; while Jameson arranged it in 1816 among the zeolites.

Calculating from the angle $I \wedge I = 126° 25'$, the prism i-$\bar{2}$ has the angle, over i-$\bar{i}$, $=90° 34'$, very near the angle $I \wedge I$ of lazulite.

554A. **Kapnicite** *Kenng.*, Ueb., 1855, and 1856–57. Probably wavellite. Occurs in fibrous radiated rounded concretions, the fibres rhombic prisms pyramidally terminated, with vitreous lustre; H.=3·5—4; G.=2·356 (Städeler). Städeler obtained (Ann. Ch. Pharm., cix. 305) $\ddot{\bar{P}}$ 35·49, $\ddot{\bar{A}}l$ 39·59, with water 24·92 (from the loss)=100, and remarks on the close approximation to wavellite. From Kapnik in Hungary.

554B. **Planerite.** Under this name Hermann has described (Bull. Soc. Nat. Mosc., xxxv. 240, 1862) a mineral from the copper mines of Gumeschefsk, in the Ural. It occurs in thin subcrystalline, botryoidal layers in the cavities of a quartz rock. H.=5; G.=2·65. Color on fresh surface verdigris-green, passing to olive-green on exposure to the air. Lustre dull. Translucent on the edges. Analysis afforded:

$$\ddot{\bar{P}}\ 33{\cdot}94 \quad \ddot{\bar{A}}l\ 37{\cdot}48 \quad \dot{C}u\ 3{\cdot}72 \quad \dot{F}e\ 3{\cdot}52 \quad \dot{H}\ 20{\cdot}93 = 99{\cdot}59.$$

From which Hermann deduces the formula $(\ddot{\bar{A}}l^3 \ddot{\bar{P}}^2 + 9\dot{H}) + \frac{1}{4}(\dot{C}u, \dot{F}e)\dot{H}$. He regards the hydrated oxyds of iron and copper as unessential, and as occurring in many other aluminous phosphates as turquois, peganite, and fischerite.

B.B. in tube decrepitates, yielding much neutral water. Easily soluble in borax, giving copper reaction. Only slightly attacked by acids, but easily decomposed by boiling with caustic soda Named after Planer. director of the mines Possibly impure wavellite

555. TROLLEITE. Trolleit *C. W. Blomstrand*, Priv. contrib., dated Dec. 9, 1867.

Compact, with indistinct cleavage.

H. a little below 6. G.=3·10. Lustre more or less vitreous. Colo pale green. Fracture even, to conchoidal.

Comp.—$\overset{...}{\overline{\mathrm{Al}}}\,\overset{.....}{\mathrm{P}}+\frac{1}{3}\,\overset{...}{\overline{\mathrm{Al}}}\,\dot{\mathrm{H}}^3$=Phosphoric acid 47·8, alumina 46·2, water 6·0=100. Analysis: C. W Blomstrand (l. c.):

	$\overset{.....}{\mathrm{P}}$	$\overset{...}{\overline{\mathrm{Al}}}$	$\overset{...}{\overline{\mathrm{Fe}}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
(⅔)	46·72	43·26	2·75	0·97	6·23=99·93.

Pyr., etc.—B.B. same as for berlinite. Scarcely attacked by acids.

Obs.—Constitutes small detached masses and veins in other phosphates, at the iron mine of Westana, in Scania, Sweden.

Named after the chemist H. G. Trolle Wachtmeister.

556. PLUMBOGUMMITE. Plomb rouge en stalactites—tantot en globules, *de Lisle*, Demeste Lettres Min., ii. 399, 1779; Crist., iii. 399, 1783. 6. *Hitchcockite*	18·74	——	25·54	29·04	20·86	0·90	1·44	——,	$\ddot{\mathrm{C}}$ 1·98, Cl 0·04, insol. 0·48=99·02 G.

[a] With some Mn^3O^3.

Berzelius made the mineral a hydrous aluminate of lead, $\dot{\mathrm{Pb}}\,\overset{...}{\overline{\mathrm{Al}}}^2+6\,\dot{\mathrm{H}}$. Damour concluded from his results that in Berzelius's investigation the phosphoric acid was precipitated with the alumina and oxyd of lead, and so lost sight of. He observes that his own analyses, though so widely different, agree in affording 1 : 1 for the O. ratio of water and alumina, and regards the alumina as present in the state of a hydrate. He writes for the formula of anal. 3, $\dot{\mathrm{Pb}}^3\overset{.....}{\mathrm{P}}+6\,\overset{...}{\overline{\mathrm{Al}}}\,\dot{\mathrm{H}}^3$. Dufrénoy inclines to adopt Damour's view (Min., iii. 294, 1856).

In Genth's analysis of hitchcockite, the O. ratio for the water and alumina is 3 : 2; for the whole $\dot{\mathrm{Pb}}$, $\overset{...}{\overline{\mathrm{Al}}}$, $\overset{.....}{\mathrm{P}}$, $\dot{\mathrm{H}}$, 2·1 : 12·2 : 10·5 : 18·5, which corresponds to $2\,\overset{...}{\overline{\mathrm{Al}}}\,\overset{.....}{\mathrm{P}}+\dot{\mathrm{Pb}}^3\overset{.....}{\mathrm{P}}+4\,\overset{...}{\overline{\mathrm{Al}}}\,\dot{\mathrm{H}}^3+10\,\dot{\mathrm{H}}$.

An earthy mineral from Rosières afforded Berthier (Ann. d. M., III. xix. 669) $\overset{.....}{\mathrm{P}}$ (with *tr.* of $\overset{.....}{\overline{\mathrm{As}}}$) 25·5, $\overset{...}{\overline{\mathrm{Al}}}$ 23·0, $\dot{\mathrm{Pb}}$ 10·0, $\dot{\mathrm{Cu}}$ 3·0, $\dot{\mathrm{H}}$ and organic matters 38 0=99·5.

Pyr., etc.—In the closed tube decrepitates and yields water. B.B. in the forceps swells up like a zeolite, colors the flame azure-blue, but is imperfectly fused. On charcoal gives in addition a faint white coating of chlorid of lead (Plattner). With soda gives metallic lead. With cobalt solution gives a blue color. With the sodium test yields a phosphid. Soluble in nitric acid.

Obs.—Occurs in clay slate at Huelgoet in Brittany, associated with galenite, blende, pyrite, and pyromorphite; also in a lead mine at Nuissière, near Beaujeu; at Roughten Gill, Cumberland at Mine La Motte, Missouri; at Canton mine, Ga., with galenite, etc. (*hitchcockite*).

Named from the Latin *plumbum*, *lead*, and *gummi*, *gum*. The identity of de Lisle's mineral (which was carnelian-like in color) with plombgomme, though questioned by de Laumont in his early paper, is admitted in his letter cited in Ann. Phil., xiv. 31, 1819.

The mineral looks usually like drops or coatings of gum, also at times somewhat like chalcedony or allophane. It differs from globular pyromorphite or blende in not being fibrous within. The *hitchcockite* occurs in botryoidal crusts and thin coatings, white, bluish, yellowish, or greenish, allophane-like, sometimes concentric in structure; Shepard gives H.=2·75—3, and says that it loses 29 p. c. on ignition.

557. CALCIOFERRITE. Calcoferrit *J. R. Blum*, Jahrb. Min. 1858, 287.

Monoclinic? Foliated massive. Cleavage: very perfect, or foliated, in one direction; traces in another at right angles to the perfect one; also in another oblique to the same. In nodules.

H.=2·5. G.=2·523—2·529, Reissig. Lustre of cleavage-face pearly. Color sulphur-yellow, greenish-yellow to siskin-green, yellowish, white. Streak sulphur-yellow. Thin laminæ translucent. Brittle.

Analysis by Reissig (l. c.), giving nearly 4 $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$, 3 $\overset{\cdot\cdot\cdot}{\bar{\mathrm{R}}}$, 6 $\dot{\mathrm{R}}$, 19 $\dot{\mathrm{H}}$; 2 $\dot{\mathrm{R}}^3\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$+2 $\overset{\cdot\cdot\cdot}{\bar{\mathrm{R}}}\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$+$\overset{\cdot\cdot\cdot}{\bar{\mathrm{R}}}\dot{\mathrm{H}}^3$+16 $\dot{\mathrm{H}}$:

$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$ 34·01 $\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}$ 24·34 $\overset{\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{l}$ 2·90 $\dot{\mathrm{M}}\mathrm{g}$ 2·65 $\dot{\mathrm{C}}\mathrm{a}$ 14·81 $\dot{\mathrm{H}}$ 20·56=99·27.

B.B. fuses easily to a shining black magnetic globule. Easily decomposed by muriatic acid.

In nodules in a bed of clay at Battenberg in Rhenish Bavaria. The exterior of the nodules is yellowish- or reddish-brown impure calcioferrite.

558. PHARMACOSIDERITE. ?Fer minéralisé par l'acide arsenique *Proust*, Ann. Chem., i. 195, 1790; Arsenicated Iron Ore *Kirwan*, ii. 189, 1796. Olivenerz, Arseniksaures Eisen in Würfeln kryst. (fr. Carharrack) *Klapr.*, Schrift. Ges. nat. Fr. Berl., 1, 161, 1786, Beitr., iii. 194, 1802; Würfelerz, var of Olivenerz, *Lenz*, ii. 18, 151, 1794. Würfelerz *Karsten*, Tab., 66, 1808. Cube Ore. Pharmakosiderit *Hausm.*, Handb., 1065, 1813.

Isometric; tetrahedral. Observed planes: *O*, 1, 2, *I*; f. 1, 29, etc. Crystals modified cubes and tetrahedrons. Cleavage: cubic; imperfect. *O* sometimes striated parallel to its edge of intersection with plane 1 (f. 29); planes often curved. Rarely granular.

H.=2·5. G.=2·9—3. Lustre adamantine to greasy, not very distinct. Color olive-green, passing into yellowish-brown, bordering sometimes upon hyacinth-red and blackish-brown; also passing into grass-green, emerald-green, and honey-yellow. Streak green—brown, yellow, pale. Subtransparent—subtranslucent. Rather sectile. Pyroelectric.

Comp.—O. ratio for $\overset{\cdot\cdot\cdot}{\bar{\mathrm{R}}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}$, $\dot{\mathrm{H}}$=4 : 5 : 5; whence 3 $\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}$+$\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}\,\dot{\mathrm{H}}^3$+12 $\dot{\mathrm{H}}$, with one-eleventh of the $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}$ replaced by $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$=Arsenic acid 39·8, phosphoric acid 2·5, sesquioxyd of iron 40·6, water 17·1=100. **Analysis:** Berzelius (Ak. H. Stockh., 354, 1824):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{A}}\mathrm{s}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\overset{\cdot\cdot\cdot}{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{H}}$
40·20	2·53	39·20	0·65	18·61, gangue 1·76=102·95.

Pyr., etc.—Same as for scorodite.

Obs.—Formerly obtained at the mines of Wheal Gorland, Wheal Unity, and Carharrack, in Cornwall, coating cavities in quartz, with ores of copper; now found in quartz at Burdle Gill in Cumberland, in small brilliant crystals; in minute tetrahedral crystals at Wheal Jane; also in Australia; at St. Leonard in France; and at Schneeberg and Schwarzenberg in Saxony.

Named from φάρμακον, *poison* (in allusion to the arsenic present), and σίδηρος, *iron*. *Würfelerz* of the Germans means *cube-ore*.

• Proust first announced the existence of an arsenate of iron, from greenish-white concretionary specimens found in Spain; but from his meagre description its identity with this species cannot be made certain.

Alt.—Has been observed altered to psilomelane, limonite ($\bar{\text{F}}\text{e}^2\dot{\text{H}}^3$), red iron ore ($\bar{\text{F}}\text{e}$).

559. CIRROLITE. Kirrolith *C. W. Blomstrand*, Priv. contrib., dated Dec. 9, 1867.

Compact, without a trace of cleavage.
H.=5–6. G.=3·08. Color pale yellow.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$, $\dot{\text{H}}$=2 : 2 : 5 : 1. Formula, $\bar{\text{A}}\text{l}^2\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+2\,\dot{\text{C}}\text{a}^3\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+3\,\dot{\text{H}}$, Blomstrand,= Phosphoric acid 41·7, alumina 20·1, lime 32·9, water 5·3=100. Analysis: Blomstrand (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$	$\bar{\text{A}}\text{l}$	$\dot{\text{F}}\text{e}$	$\dot{\text{M}}\text{n}$	$\dot{\text{P}}\text{b}$	$\dot{\text{M}}\text{g}$	$\dot{\text{C}}\text{a}$	$\dot{\text{H}}$
(⅜) 41·17	20·54	0·91	2·24	0·11	0·21	29·37	5·06=99·61,

after removal of 4·60 not dissolved in the acid solution, of which 3·17 was silica.

Pyr., etc.—B.B. fuses very easily to a white enamel. With soda a manganese reaction. Decomposed on digestion in fine powder in muriatic acid.

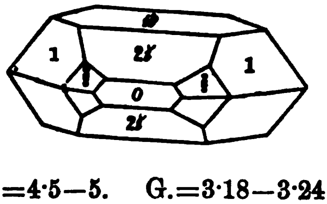
Obs.—Occurs at the iron mine of Westana, in Scania, Sweden.

Named from *κιῤῥός, pale yellow.*

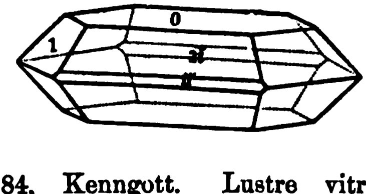
560. CHILDRENITE. *Levy*, Brande's J., xvi. 274, 1823.

Orthorhombic. *I* ∧ *I*=111° 54′, *O* ∧ 1-ī=136° 26′; *a* : *b* : *c*=0·9512 : 1 : 1·4798. Observed planes as in the annexed figures, with also ½-ĭ. *O* ∧ 2-ĭ=127° 53′, *O* ∧ 1=131° 4′, *O* ∧ ½=142° 35′, *O* ∧ *i*-ĭ=90°, 1 ∧ 1, mac., 130° 4′, brach., or over 2-ĭ, 102° 41′, bas., 97° 52′, 2-ĭ ∧ 2-ĭ, ov. *O*,= 75° 46′, B. & M. Plane *O* sometimes wanting, and the form a double six-sided pyramid, made up of the planes 1, 2-ĭ, with *i*-ĭ small. Cleavage: *i*-ĭ, imperfect.

484



485



H.=4·5–5. G.=3·18–3·24; 3·184, Kenngott. Lustre vitreous, inclining to resinous. Color yellowish-white and pale yellowish-brown, also brownish-black. Streak white, yellowish. Translucent. Fracture uneven.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{R}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$, $\dot{\text{H}}$=4 : 3 : 7 : 7; or less nearly 4 : 3 : 7½ : 7½, Rammelsberg, who writes the formula $2\,\dot{\text{R}}^4\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+\bar{\text{A}}\text{l}^2\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+15\,\dot{\text{H}}$=Phosphoric acid 28·9, alumina 14·0, protoxyd of iron 29·3, protoxyd of manganese 9·5, water 18·3=100. Perhaps $(\frac{4}{7}\,\dot{\text{R}}^3+\frac{3}{7}\,\bar{\text{A}}\text{l})^5\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}^3+15\,\dot{\text{H}}$. But a new analysis is needed. Analysis: Rammelsberg (Pogg., lxxxv. 435):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$ 28·92 $\bar{\text{A}}\text{l}$ 14·44 $\dot{\text{F}}\text{e}$ 30·68 $\dot{\text{M}}\text{n}$ 9·07 $\dot{\text{M}}\text{g}$ 0·14 $\dot{\text{H}}$ 16·98=100·23 Ramm.

Pyr., etc.—In the closed tube gives off neutral water. B.B. swells up into ramifications, and fuses on the edges to a black mass, coloring the flame pale green. Heated on charcoal turns black and becomes magnetic. With soda gives a reaction for manganese. With borax and salt of phosphorus reacts for iron and manganese. Soluble in muriatic acid.

Obs.—Occurs in crystals and crystalline coats, on spathic iron, pyrite, or quartz, and sometimes with apatite, near Tavistock, and at the George and Charlotte mine, and also at Wheal Crebor, in

Devonshire; on slate at Crinnis mine in Cornwall. Crystals 1 in. long have been observed. They look a little like siderite, but are more lustrous and of greater hardness.

In U. States, at Hebron, Me., in minute hair-brown prismatic crystals, with amblygonite (f. 485 by Cooke, and an octahedral form, Am. J. Sci., II. xxxvi. 258).

If the dome 2-ī be made the fundamental vertical prism, then *I* ∧ *I*=104° 14′, 1-ī ∧ 1-ī, top,=73°, 1-ī ∧ 1-ī, ib.,=87° 14′; the cleavage macrodiagonal; *a* : *b* : *c*=1·3514 : 1 : 1·2858.

Named after Mr. Children.

561. ATTACOLITE. Attakolith *C. W. Blomstrand*, Priv. contrib., dated Dec. 9, 1867.

Massive, indistinctly crystalline.

H.=5. G.=3·09. Color pale red.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$, $\dot{\mathrm{H}}$, after separating 8·60 $\ddot{\mathrm{Si}}$ as free silica=6 : 15 : 20 : 6. The uncertainty as to whether the silica is free or combined renders the composition and formula doubtful. Analysis: C. W. Blomstrand (l. c.):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
(½)	36·06	29·75	3·98	8·02	0·33	13·19	0·45	6·90=98·68.

Pyr., etc.—B.B. fuses easily, and, when more heated, with intumescence, to a brownish-yellow glass. With soda a strong manganese reaction. Very incompletely decomposed by acids.

Obs.—From the iron mine of Westana, in Scania, Sweden.

Named from ἀττακός, *salmon*, alluding to the color.

562. AUGELITE. Augelith *C. W. Blomstrand*, Priv. contrib., dated Dec. 9, 1867.

Massive. Cleavage: distinct in three directions, and generally easily obtained.

G.=2·77. Lustre of cleavage surface strongly pearly. Colorless, but generally pale red.

Comp.—$\dddot{\bar{\mathrm{Al}}}^2\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+3\dot{\mathrm{H}}$=Phosphoric acid 35·3, alumina 51·3, water 13·4=100. Analysis: C. W. Blomstrand (l. c.):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dddot{\bar{\mathrm{Fe}}}$	$\dddot{\bar{\mathrm{Mn}}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
(½)	35·61	48·30	0·75	0·81	1·09	13·04=99·60.

The mineral is often intimately mixed with silica, and not easily separated from it.

Pyr., etc.—Yields much water in the glass tube. B.B. infusible. Scarcely affected by acids.

Obs.—Occurs imbedded in other phosphates at the iron mine of Westana, in Scania, Sweden.

Named from αὐγή, *lustre*.

563. TURQUOIS. ?Callais, ?Callaina, *Plin.*, xxxvii. 56, 33. Firuzegi *Pers.* Turques, Turquois pt., of the 16th century and later (Turques, Fabyan's Chronicle). Türkis pt. *Germ.*, Turchesa *Ital.*, Turquoise *Fr.* Turquoise *J. B. Tavernier*, Voy. en Turquie, en Persie, etc., Paris, 1678. Turchine *Bocconi*, Museo di Fisica, etc., 278, 1697. Orientalischer Türkis *Demetrius Agaphi* N. *Nord.* Beytr., v. 261, *Pallas*, ib., 265. Turquois orientale, Calaite, Agaphite, Johnite, *G. Fischer*, Mém. Soc. Imp. N. Moscou, i. 1806; also his Onomasticon Min. Mus. Imp. Moscou, 1811, and Essai sur la Turquoise, Moscou, 1816, of which Abstr. in Ann. Phil., xiv. 406, 1819. *John*, Mem. Soc. Imp. N. Moscou, i. 1806, Schw. J., iii. 93, 1807 (with analyses and assertion that it is no *Odontolite*). Hydrargillite pt. *Hausm.*, Handb., 444, 1813. Turquoise de vieille roche (in distinction from Odontolite, or T. de nouvelle roche, called also Occidental Turquois). Kallait, Kalait, *Germ.*

Reniform, stalactitic or incrusting. Cleavage none.

H.=6. G.=2·6–2·83; 2·621, Hermann. Lustre somewhat waxy, feeble. Color sky-blue, bluish-green to apple-green. Streak white or greenish. Feebly subtrarslucent—opaque. Fracture small conchoidal.

Comp.—O. ratio fr. anal. 1 and 3, for $\overset{\cdot\cdot\cdot}{\overline{\rm Al}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\rm P}$, $\dot{\rm H}=6:5:5$; whence $\overset{\cdot\cdot\cdot}{\overline{\rm Al}}{}^2\overset{\cdot\cdot\cdot\cdot\cdot}{\rm P}+5\dot{\rm H}$=Phosphoric acid 32·6, alumina 46·9, water 20·5=100. Analyses: 1, John (Ann. d. M., II. iii. 231); 2, Zellner (Isis, 1834, 637); 3, Hermann (J. pr. Ch., xxxiii. 282); 4, Church (Ch. News, x. 290):

		$\overset{\cdot\cdot\cdot\cdot\cdot}{\rm P}$	$\overset{\cdot\cdot\cdot}{\overline{\rm Al}}$	$\dot{\rm H}$	Cu	
1	Silesia	30·90	44·50	19·00	3·75	$\dot{\rm Fe}$ 1·80=99·95 John.
2.	"	38·90	54·50	1·00	1·50	$\overset{\cdot\cdot\cdot}{\overline{\rm Fe}}$ 2·8=98·70 Zellner.
3.	*Blue Oriental*	27·34	47·45	18·18	2·02	" 1·10, $\overset{\cdot\cdot\cdot}{\overline{\rm Mn}}$ 0·50, $\dot{\rm C}{\rm a}^3\overset{\cdot\cdot\cdot\cdot\cdot}{\rm P}$ 3·41=100 H.
4.	Nichabour, Persia	32·86	40·19	19·34	5·27	$\dot{\rm Fe}$ 2·21, $\dot{\rm Mn}$ 0·36=100·23* C.; G.=2·75.

* After subtracting 0·74 Si O^2 and 0·40 hygroscopic water.

The green oriental turquois afforded Hermann only 5·64 p. c. of phosphoric acid, and is evidently a mechanical mixture, containing but little turquois. Specific gravity of the last 2·621. John in his early analysis did not detect the phosphoric acid; he obtained $\overset{\cdot\cdot\cdot}{\overline{\rm Al}}$ 73·0, $\dot{\rm C}$u 4·5, $\overset{\cdot\cdot\cdot}{\overline{\rm Fe}}$ 4·0, $\dot{\rm H}$ (or loss) 18=99·5.

Pyr., etc.—In the closed tube decrepitates, yields water, and turns brown or black. B.B. in the forceps becomes brown and assumes a glassy appearance, but does not fuse; colors the flame green; moistened with muriatic acid the color is at first blue (chlorid of copper). With the sodium test gives phosphuretted hydrogen. With borax and salt of phosphorus gives beads in O.F. which are yellowish-green while hot and pure green on cooling. With salt of phosphorus and tin on charcoal gives an opaque red bead (copper). Soluble in muriatic acid.

Obs.—Occurs in clay slate, in a mountainous district in Persia, not far from Nichabour. According to Agaphi, the only naturalist who has visited the locality, turquois occurs only in veins, which traverse the mountain in all directions. Fischer, in 1816, named the different varieties Calaite, Agaphite (or conchoidal T.), and Johnite (or quartzy T.). Pieces of the size of a hazelnut are considered very large. An impure variety is found in Silesia, and at Oelsnitz in Saxony; near the well of Nasaiph between Suez and Sinai. W. P. Blake refers here a hard, yellowish- to bluish-green stone (which he identifies with the *chalchihuitl* of the *Mexicans*) from the mountains Los Cerillas, 20 m. S.E. of Santa Fé; H.= 6; G.=2·426—2·651 (Am. J. Sci., II. xxv. 227). A pale green turquois occurs in the Columbus district, Nevada.

Turquois receives a good polish, and is highly esteemed as a gem. The Persian king is said to retain for his own use all the larger and finely tinted specimens.

The *Callais* of Pliny is generally regarded as turquois, and probably rightly so. But all he says of it is, "Callais sapphirum imitatur, candidior et litoroso mari similis," resembling sapphire (that is, *lapis-lazuli*) in color, but paler, and like the sea toward the shore; indicating a greenish-blue tint and degree of opacity corresponding well enough with much turquois.

The *Callaina* also of Pliny (to which he devotes a long chapter) is referred to this species, and with even better reason. It was a stone of a pale green color, and was obtained, according to him, amid inaccessible rocks in the countries that lie at the back of India, near Mt. Caucasus, etc. He also states that it was remarkable for its size, and was full of holes and foreign substances, which it is difficult to reconcile with the true turquois. But he speaks in the next sentence of a kind from Carmania (a district of Persia) as of better quality and clearer, and this may have been real turquois. He says that no stones were more easily imitated, which is very true of turquois. He also remarks that the beauty of the Callaina is greatly heightened by a setting of gold, the contrast peculiarly befitting it.

Pliny also speaks of another stone called *Callaica* (xxxvii. 56), and says of it: "Callaicam vocant e turbido callaino; ferunt pluris conjunctis semper inveniri;" it is so called because it is a turbid callaina, and they are found together. He also remarks that the stone called "*Augetis* (xxxvii. 54) multis non alia videtur quam callaina," by many is thought to be nothing but callaina. (See further CALLAINITE, p. 572).

The *Persian smaragdus*, or emerald, alluded to by Pliny (xxxvii. 18, citing from Democritus), as "without transparency, agreeable and uniform in color, satisfying the vision without allowing it to penetrate it," may have been turquois; yet, as with most of Pliny's descriptions (owing to his mixing different things of similar aspect), when all the other characters given are weighed they leave doubt.

It is probable that the turquois—oriental and occidental—was as commonly used in Persia as a gem in ancient times as now. The name *turquois* is French in form, and means *Turkish*, a *Turkish gem*, the gem having come into Europe through Turkey.

Most of the turquois (not artificial) used in jewelry in former centuries, as well as the present, and that described in the early works on minerals, was *bone-turquois* (called also *odontolite*, from ὀδοὺς, *tooth*), which is fossil-bone, or tooth, colored by a phosphate of iron. Its organic origin becomes manifest under a microscope. Moreover, true turquois, when decomposed by muriatic acid, gives a fine blue color with ammonia, which is not true of the odontolite.

564. PEGANITE. Peganit *Breith.*, Schw. J., lx. 308, 1830.

Orthorhombic. In rhombic prisms, with the acute lateral edge truncated; angle of the prism about 127° and 53°. Cleavage: basal, and brachydiagonal, imperfect.

H.=3—3·5. G.=2·492—2·501. Lustre greasy to vitreous. Color deep green, greenish-gray, greenish-white. Streak white.

Comp.—$\bar{\text{Al}}^2\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+6\dot{\text{H}}$, Hermann,=Phosphoric acid 31·1, alumina 45·2, water 23·7=100. Analysis by Hermann (J. pr. Ch., xxxiii. 287):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$ 30·49 $\bar{\text{Al}}$ 44·49 $\dot{\text{H}}$ 22·82 $\dot{\text{Cu}}$, $\bar{\text{Fe}}$, gangue 2·20=100 Hermann.

Pyr., etc.—In the closed tube yields water, and assumes a violet or rose color. B.B. cracks open, becomes violet, but does not fuse. Gives but a faint copper reaction, but in other respects like turquois. The powdered mineral gives a fine blue with cobalt solution.

Obs.—Occurs in crusts, consisting of small prismatic crystals, at Striegis, near Freiberg, Saxony.

Erdmann analyzed a Striegis mineral (*Striegisan* of Breithaupt) with a very different result, as seen from the analyses under WAVELLITE, to which species the specimens evidently pertain. *Peganite* has till recently been placed under wavellite.

Named from *πήγανον*, *an herb*, in allusion to the color.

565. FISCHERITE. *Schtschurovski*, *Hermann*, J. pr. Ch., xxxiii. 285, 1844.

Orthorhombic, Kokscharof. $I \wedge I$=118° 32′; $a : b : c = x : 1 : 1·189$. $I \wedge i\text{-}\breve{2}$, bevelling plane,=160° 48′, $i\text{-}\breve{2} \wedge i\text{-}\breve{2}$=99° 52½′ and 80° 7½′, $i\text{-}\breve{2} \wedge i\text{-}\breve{i}$=139° 56′. Mostly in small six-sided prisms. Also crystalline, massive.

H.=5. G.=2·46. Lustre vitreous. Color grass-green to olive-green, and verdigris-green. Translucent.

Comp.—$\bar{\text{Al}}^2\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+8\dot{\text{H}}$=Alumina 41·8, phosphoric acid 28·9, water 29·3=100. Analysis: Hermann (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$ 29·03 $\bar{\text{Al}}$ 38·47 $\bar{\text{Fe}}$ and $\bar{\text{Mn}}$ 1·20 $\dot{\text{Cu}}$ 0·80 $\dot{\text{H}}$ 27·50=100.

Pyr., etc.—B.B. becomes white, and clouded; yields much water, but no fluorine. Soluble in sulphuric acid.

Obs.—From Nischne Tagilsk, where it occurs in veins in a ferruginous sandstone and clay slate.

565A. VARISCITE *Breith.* (J. pr. Ch., x. 506, 1837). Contains the same ingredients as the above, but is not yet accurately analyzed. Reniform; apple-green; with white shining streak, weak greasy lustre, and translucent. Yields water in a matrass. B.B. in the forceps infusible, but becomes white; in the outer flame, colors the flame deep bluish-green; with borax and salt of phosphorus forms a pale yellowish-green glass; with soda fuses with effervescence, but imperfectly; with cobalt solution becomes blue. Occurs in quartz and siliceous slate at Messbach in Saxon Voigtland. Named from Variscia (Voigtland).

566. TAVISTOCKITE. Hydrated Calcium-aluminic Phosphate (?) *A. H. Church*, J. Ch. Soc., II. iii. 263, 1865. Tavistockite *Dana*.

In microscopic acicular crystals, sometimes aggregated in irregular stellate groups, constituting a white pearly powder.

Lustre pearly. Color white. Transparent to translucent. Fragile.

Comp.—O. ratio for $\dot{\text{R}}+\bar{\text{R}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$, $\dot{\text{H}}$=6 : 5 : 3; whence $(\tfrac{1}{2}\dot{\text{C}}\text{a}^3+\tfrac{1}{2}\bar{\text{Al}})^2\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+3\dot{\text{H}}$=Phosphoric acid 30·41, alumina 22·06, lime 35·97, water 11·56=100. Analyses: Church (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$	$\overset{\cdots}{\overline{\text{Al}}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$
30·36	22·40	36·27	12·00=101·03 Church.

Pyr., etc.—B.B. "incandesces" and becomes opaque. With nitrate of cobalt gives a blue color. Colorless bead with borax. Difficultly soluble in acids.

Obs.—Occurs at Tavistock, Devonshire, in cavities with quartz crystals, with pyrite, chalcopyrite, and childrenite.

567. CHENEVIXITE. Chenevixite *Adam*, *F. Pisani*, C. R., lxii. 690, 1866.

Massive—compact.

H.=4·5. G.=3·93? Lustre vitreous. Color dark green Streak yellowish-green.

Comp.—O. ratio for $\dot{\text{R}}+\overset{\cdots}{\overline{\text{R}}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\text{As}}$, $\dot{\text{H}}$=6 : 5 : 3 nearly, with O. ratio of $\overset{\cdots}{\overline{\text{Fe}}}$, $\dot{\text{Cu}}$=7½ : 6½. Formula $(\overset{\cdots}{\overline{\text{Fe}}}, \dot{\text{Cu}}^{3})^{2}\overset{\cdot\cdot\cdot\cdot\cdot}{\text{As}}+3\dot{\text{H}}$; or perhaps $\overset{\cdots}{\overline{\text{Fe}}}\overset{\cdot\cdot\cdot\cdot\cdot}{\text{As}}+3\dot{\text{Cu}}\dot{\text{H}}$; $\overset{\cdot\cdot\cdot\cdot\cdot}{\text{As}} : \overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$=9 : 1. Analyses: 1, Chenevix (l. c.); 2, Pisani (l. c.):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{As}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$	$\overset{\cdots}{\overline{\text{Fe}}}$	$\dot{\text{Cu}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$
1. Cornwall	33·5	—	27·5	22·5	—	12, sand 3=98·5 Chenevix.
2. "	32·20	2·30	25·10	31·70	0·34	8·66=100·30 Pisani.

Pisani refers here the analysis by Chenevix. 10·3 p. c. of sand are removed from anal. 2.

Pyr., etc.—In the closed tube decrepitates and yields water; becomes brown after calcination. B.B on charcoal fuses easily, giving out arsenical fumes, and leaving a black magnetic scoria with grains of copper. Easily soluble in the acids.

Obs.—From Cornwall, involved in a quartz rock in small compact masses, from which gangue it is difficult to separate it entirely.

568. DUFRENITE. Strahlstein (var.) *Jordan*, Min., etc., Reisebem., 243, 1803. Grüneisenstein (strahlichter) *Ullmann*, Syst. Tab. Uebers., 152, 319, 1814. Chalkosiderit *Ullmann*, ib., 323. Fasriche Grün-Eisenerde *W.* Dufrenite *Brongn.*, Tabl., 20, 1833. Green Iron Ore. Kraurit *Breith.*, Handb., 152, 1841.

Delvauxene *Dumont*, L'Institut, 121, 1839, *Delvaux*, Bull. Ac. Brux., 147, 1838. Delvauxit *Haid.*, Handb., 512, 1845.

Orthorhombic. $I \wedge I$ about 123°. Cleavage: brachydiagonal. Also massive, in nodules; radiated fibrous, with a drusy surface.

H.=3·5—4. G.=3·2—3·4; 3·227, Dufr. Lustre silky, weak. Color dull leek-green, olive, or blackish-green; alters on exposure to yellow and brown. Streak siskin-green. Subtranslucent.

Comp., Var.—$\overset{\cdots}{\overline{\text{Fe}}}^{2}\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+3\dot{\text{H}}$=Phosphoric acid 27·5, sesquioxyd of iron 62·0, water 10·5=100 $\overset{\cdots}{\overline{\text{Fe}}}$, $\overset{\cdots}{\overline{\text{Al}}})^{2}\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}+3\tfrac{1}{2}\dot{\text{H}}$, Pisani. Schnabel's analysis makes part of the iron protoxyd.

Analyses: 1, Vauquelin (Ann. Ch. Pharm., xxx. 202); 2, Karsten (Arch. f. Bergb. u. Hütt., xv. 243); 3, Schnabel (Ramm. Min. Ch., 329); 4, Pisani (C. R., liii. 1020); 5, Kurlbaum (Am. J. Sci., II. xxiii. 423); 6, 7, Dumont (L'Institut, No. 276); 8, Delvaux (Bull. Acad. Brux., 1838, 147); 9, 10, Diesterweg (B. H. Ztg., xxii. 257):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\text{P}}$	$\overset{\cdots}{\overline{\text{Al}}}$	$\overset{\cdots}{\overline{\text{Fe}}}$	$\overset{\cdots}{\overline{\text{Mn}}}$	$\dot{\text{Fe}}$	$\dot{\text{H}}$

10. " *red*	25·20	—	59·14	2·33	—	13·98=100·65 Diesterweg

Church (Ch. News, x. 157) shows that dufrenite contains 10·55 p. c. of water, corresponding to the above formula; it loses no water at 100° C. He observes also that the mineral is usually so mixed with hematite that it is difficult to separate it for analysis.

Church also demonstrates (l. c., 145) that the *delvauxite* of Liege is only a *wet* dufrenite. It lost in his trial 20·33 p. c. over sulphuric acid, and nearly 6 p. c. more on heating to 100° C.; the total percentage of water having been found to be 37·23, whence the essential water is only 10–11 p. c., as in dufrenite. He detected a trace of lime. The color of delvauxite given is yellowish-brown to brownish-black or reddish, or that of altered dufrenite; and G.=1·85. An *altered* dufrenite gave Diesterweg (l. c.) $\dddot{\text{P}}$ 6·25, $\overline{\text{Fe}}$ 80·03, $\dot{\text{H}}$ 14·03=100·34.

Pyr., etc.—Same as for vivianite, but less water is given out in the closed tube. B.B. fuses easily to a slag.

Obs.—Occurs near Anglar, Dept. of Haute Vienne, and at Hirschberg in Westphalia (the localities of the specimens, according to Dufrénoy, originally named *dufrenite*); at Rocheforten-Terre, Morbihan, France; Eisenfeld near Siegen. Also at Allentown, N. J., as a fibrous leek-green coating, sometimes half an inch thick, in the Green Sand formation; it changes to brown in altering to limonite.

The *delvauxene* is from Berneau, near Visé, in Belgium.

Named after the French mineralogist Dufrénoy.

GLOBOSITE. This name is given by Breithaupt (B. H. Ztg., xxiv. 321, 1865) to a mineral occurring at the Arme Hilfe mine near Hirschberg, in small globular concretions. H.=5–5·5. G.=2·825–2·827. Lustre greasy to adamantine. Color wax-yellow to yellowish-gray. Streak white. Brittle. Analysis on a small quantity of the mineral afforded Fritzsche (l. c.) $\dddot{\text{P}}$ 28·89, $\dddot{\text{As}}$ *tr.*, $\ddot{\text{Si}}$ 0·24, $\overline{\text{Fe}}$ 40·86, $\dot{\text{Cu}}$ 0·48, $\dot{\text{Mg}}$ 2·40, $\dot{\text{Ca}}$ 2·40, $\dot{\text{H}}$ and F 23·94=100·05. B.B. in tube yields water; by stronger heat gives the fluorine reaction, depositing a ring of silica, and leaving a red residue not magnetic, but giving with fluxes the reaction for iron. Slowly soluble in muriatic acid. It occurs as above with massive and pulverulent limonite; also in the cobalt mine of Schneeberg in Saxony, with quartz and hypochlorite.

569. CACOXENITE. Kakoxen *J. Steinmann*, Vortr. Böhm. Ges., Prag, 1825. Cacoxene

Occurs in radiated tufts of a yellow or brownish-yellow color. H.=3–4. G.=3·38. Becomes brown on exposure.

Comp.—Supposed to be an iron-wavellite. O. ratio, fr. anal. 3, 4, for $\overline{\text{R}}$, $\dddot{\text{P}}$, $\dot{\text{H}}$=6 : 5 : 12, whence $\overline{\text{Fe}}^2 \dddot{\text{P}} + 12 \dot{\text{H}}$, from Richardson's analysis. Analysis 5 corresponds to $\overline{\text{Fe}}^3 \dddot{\text{P}}^2 + 20 \dot{\text{H}}$. Analyses: 1, Steinmann (Leonh. Orykt., 750); 2, Holger (Baumg. ZS., viii. 129); 3, Richardson (Thomson's Min., i. 476); 4, 5, v. Hauer (Jahrb. G. Reichs. 1854, 67):

	$\dddot{\text{P}}$	$\overline{\text{Fe}}$	$\overline{\text{Al}}$	$\dot{\text{Ca}}$	$\dddot{\text{Si}}$	$\dot{\text{H}}$, F

3. "	20·5	43·1	——	1·1	2·1	30·2, $\dot{\text{Mg}}$ 0·9=97 9 Richardson.
4. " *fibrous yw.*	19·63	47·64	——	——	——	32·73=100 Hauer.
5. " *globular*	25·71	41·46	——	——	——	32·83=100 Hauer.

The alumina of the earlier analyses was from impurities.

Pyr., etc.—Yields water, with trace of fluorine. Fuses on the edges to a black shining slag, and colors the outer flame bluish-green. Reactions for iron. Soluble in muriatic acid.

Obs.—Occurs at the Hrbeck mine, near Zbirow in Bohemia, along with earthy limonite. Stated by Zepharovich to be sometimes derived from the alteration of *barrandite*.

570. ARSENIOSIDERITE. Arseniosiderite *Dufr.*, Ann. d. M., IV. ii. 343, 1842. Arsenokrokit, Arsenocrocites, *Glocker*, Syn., 226, 1847.

In fibrous concretions of a yellowish-brown and somewhat golden color, resembling cacoxenite; the fibres large and easily separable between the fingers.

H.=1–2. G.=3·520, Dufr.; 3·88, Ramm. Lustre silky. Powder yellowish-brown, rather deeper in color than that of yellow ochre. When rubbed in a mortar the powder adheres to the pestle.

Comp.—$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}{}^5$, $\dddot{\mathrm{\bar{F}e}}{}^8$, $\dot{\mathrm{Ca}}{}^6$, $\dot{\mathrm{H}}{}^{15}$, or $\dot{\mathrm{Ca}}{}^6 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}} + 4\, \dddot{\mathrm{\bar{F}e}}{}^2 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}} + 15\, \dot{\mathrm{H}}$=Arsenic acid 37·9, sesquioxyd of iron 42·1, lime 11·1, water 8·9=100. Analyses: 1, Dufrénoy (Ann. d. M., IV. ii. 343, 182); 2, 3, Rammelsberg (2d Suppl., 20, Pogg., lxviii. 508):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}$	$\dddot{\mathrm{\bar{F}e}}$	$\dddot{\mathrm{\bar{M}n}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	34·26	41·31	1·29	8·43	0·76	8·75, $\dddot{\mathrm{Si}}$ 4·04=98·84 Dufrénoy.
2.	[39·16]	40·00	*tr.*	12·18	—	8·66=100 Rammelsberg.
3.	[37·36]	38·31	*tr.*	12·08	—	8·68, $\dddot{\mathrm{Si}}$ 3·57=100 Ramm.

According to Fournet, arseniosiderite is essentially cacoxene with the phosphoric acid replaced by arsenic acid, and having the corresponding formula $\dddot{\mathrm{\bar{F}e}}{}^4 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}{}^3 + 18\, \dot{\mathrm{H}}$; but this exceeds the proportion of water by nearly one-half, and does not take into account the lime.

Pyr., etc.—Like scorodite.

Obs.—Occurs in a manganese bed at Romanèche, Department of Saone-et-Loire, France.

Named from *arsenic* and σίδηρος, *iron*. Changed to *arsenocrocite* (fr. κρόκη, *fibre*) by Glocker because of a previous use of arsenosiderite (see p. 76).

571. EVANSITE. *D. Forbes*, Phil. Mag., IV. xxviii. 341, 1864.

Massive; reniform or botryoidal.

H.=3·5—4. G.=1·939. Lustre vitreous or resinous; internally waxy. Colorless, or milk-white; sometimes tinged with yellow or blue. Streak white. Translucent, subtranslucent. Fracture subconchoidal.

Comp.—O. ratio for $\dddot{\bar{\mathrm{R}}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$, $\dot{\mathrm{H}}$=9 : 5 : 18, whence $\dddot{\mathrm{\bar{A}l}}{}^2 \overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}} + \dddot{\mathrm{\bar{A}l}}\, \dot{\mathrm{H}}{}^3 + 15\, \dot{\mathrm{H}}$, Dana,=Phosphoric acid 18·4, alumina 39·7, water 41·9=100. Analysis: Forbes (l. c.):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dddot{\mathrm{\bar{A}l}}$	$\dot{\mathrm{H}}$
(½)	19·05	39·31	39·95, insol. 1·41=99·72 Forbes.

Pyr., etc.—B.B. in tube yields neutral water, decrepitates, leaving milk-white powder. Infusible. Moistened with sulphuric acid colors the flame green. On charcoal with cobalt solution gives intense blue. With fluxes trace of iron. Soluble in sulphuric, nitric, and muriatic acids. Fluorine not detected.

Obs.—Occurs at Zsetcznik, Hungary, as reniform or globular concretions on brown hematite.

Brought in 1855 from Hungary, by Brooke Evans, of Birmingham, England, after whom it was named. It was labelled allophane.

572. TORBERNITE.

Mica viridis cryst. (fr. Joh.) *v. Born*, Lithoph., i. 42, 1772. Grüner Glimmer (fr. Saxony) *Wern.*, Ueb. Cronst., 217, 1780; Torberit *Wern.* (earliest name); *Karst.*, Ueb. Wern. Verbess., 43, 1793 [later spelt *Torbernit*, as in Ludwig's Wern., i. 308, 1803); Chalkolith [put near Chlorite] *Wern.*, Bergm. J., 376, 1789; Urankalk durch Kupfer gefärbt, Uranites spathosus pt., *Klapr.*, Schrift. Ges. N. Berl., ix. 273, 1789; Beitr., ii. 217, 1797. Uranglimmer *Wern.*, 1800, Ludwig, i. 55, 1803. $O \wedge 2\text{-}i=115\ 53$ — $2\text{-}i \wedge 2\text{-}i$, basal,$=128\ 15$

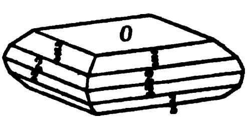
486



Cornwall.

Cleavage: basal highly perfect, micaceous. Unknown massive or earthy

H.=2—2·5. G.=3·4—3·6. Lustre of *O* pearly, of other faces subadamantine. Color emerald- and grass-green, and sometimes leek-, apple-, and siskin-green. Streak somewhat paler than the color. Transparent—subtranslucent. Fracture not observable. Sectile. Laminæ brittle and not flexible. Optically uniaxial; double refraction negative.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{U}}$, $\dddot{\text{P}}$, $\dot{\text{H}}$=1 : 6 : 5 : 8; whence $\bar{\text{U}}^2\dddot{\text{P}}+\dot{\text{Cu}}\dot{\text{H}}+7\dot{\text{H}}$, Dana. Analyses: 1, R. Phillips (l. c.); 2, Berzelius (l. c.); 3, Werther (J. pr. Ch., xliii. 384); 4, Pisani (C. R., lii. 817); 5, Church (Ch. News, xii. 183):

	$\dddot{\text{P}}$	$\bar{\text{U}}$	$\dot{\text{Cu}}$	$\dot{\text{H}}$
1. Cornwall	16·0	60·0	9·0	14·5=99·5 Phillips.
2. "	15·57	61·29	8·44	15·05=100·45 Berzelius.
3. "	14·34	59·03	8·27	15·39, $\ddot{\text{Si}}$ 0·49, earthy substance 0·41 Werther
4. "	14·0	59·67	8·50	15·00, sand 0·40=97·57 Pisani.
5. "	13·94	61·00	8·56	14·16, $\dddot{\text{As}}$ 1·96, $\dot{\text{Ca}}$ 0·62=100·24 Church.

Pyr., etc.—In the closed tube yields water. In the forceps fuses at 2·5 to a blackish mass, and colors the flame green. With salt of phosphorus gives a green bead, which with tin on charcoal becomes on cooling opaque red (copper). With soda on charcoal gives a globule of copper. Affords a phosphid with the sodium test. Soluble in nitric acid.

Obs.—Gunnis Lake formerly afforded splendid crystallizations of this species, and also Tincroft and Wheal Buller, near Redruth, and elsewhere in Cornwall. Found also at Johanngeorgenstadt, and Eibenstock and Schneeberg, in Saxony; in Bohemia, at Joachimsthal and Zinnwald; in Belgium, at Vielsalm. A variety from Providence in Cornwall is in 8-sided tables with a low pyramid, and has a leek-green color, with G.=3·329—3·372 (Breith., B. H. Ztg., xxiv. 303).

The angle *O* ∧ 2 is given by Mohs, Haidinger, and Naumann =108° 29′; by Hessenberg (Min. Not., vi. 41) 108° 38′: Kokscharof (Min. Russl., v. 35) 108° 56′; the mean of his measurements of Cornwall and Schlackenwald crystals being 108° 53′ 23″ and 71° 5′ 21″. Similar figures are given by Greg & Lettsom, Min., 384. The angles of B. & M. do not agree with any of the measurements.

First named *torberite* (*torbernite*) by Werner, after the chemist Torber Bergmann [*Lat* Torbernus, as written by Bergmann himself]. Then, this naming after persons having been denounced as an innovation (see Karsten's Werner's Verbess., 43, 1793), Werner substituted *Chalcolite* (fr. χαλκός, *copper*, signifying, as he says, "ein Kupfer haltender Stein") in allusion to Bergmann's determination in 1780 that the mineral was muriate of copper. When, finally, it was shown by Klaproth to be an ore of uranium instead of copper, Werner, with Karsten and others, threw aside *chalcolite*, because false in signification, and used *Uranglimmer* (uran-mica). Chalcolite has since crept back again, but is no more appropriate now than it was sixty years ago. The name *torberite* was written as it should be, *torbernite*, by some mineralogists of last century.

Both this species and the autunite have gone under the common name of *uranite*; the former also as *Copper-uranite*, the latter *Lime-uranite*.

573. AUTUNITE. Var. of Uranglimmer, Urankalk, or Chalcolite, *of authors prior to* 1819. Sel à base de chaux, ou l'oxide d'urane joue le rôle d'acide, *Berz.*, N. Syst. Min., 295, 1819. Uranit *Berz.*, Jahresb., iv. 46, 1823. Kalk-Uranit *Germ.* Lime-Uranite. Autunite *B. & M.*, 519, 1852. Calcouranit *Breith.*, B. H. Ztg., xxiv. 302, 1865.

Orthorhombic; but form very nearly square, and crystals resembling closely those of torbernite. Cleavage: basal eminent, as in torbernite. *O* ∧ $2\text{-}\bar{i}$=109° 6′, *O* ∧ $2\text{-}\breve{i}$=109° 17′, $2\text{-}\breve{i}$ ∧ $2\text{-}\bar{i}$=95° 52′, $2\text{-}\bar{i}$ ∧ 1 (plane on edge $2\text{-}\bar{i}/2\text{-}\breve{i}$)=138° 30′, Descl. Planes $2\text{-}\bar{i}$, $2\text{-}\breve{i}$ correspond to 2 of torbernite.

H.=2—2·5. G.=3·05—3·19. Lustre of *O* pearly; elsewhere subadamantine. Color citron- to sulphur-yellow. Streak yellowish. Translucent. Optically biaxial, Descl.

Comp.—O. ratio for $\dot{\text{R}}$, $\bar{\text{U}}$, $\dddot{\text{P}}$, $\dot{\text{H}}$=1 : 6 : 5 : 8; whence $\bar{\text{U}}^2\dddot{\text{P}}+\dot{\text{Ca}}\dot{\text{H}}+7\dot{\text{H}}$, Dana,=Phosphoric acid 15·7, oxyd of uranium 62·7, lime 6·1, water 15·5=100. Analyses: 1, Berzelius (l. c.); 2 Pisani (C. R., lii. 817):

	$\dddot{\text{P}}$	$\bar{\text{U}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$, $\dot{\text{Mn}}$	$\dot{\text{Ba}}$	$\ddot{\text{Sn}}$	$\dot{\text{H}}$
1. Autun	15·20	61·73	5·88	0·20	1·57	0·06	15·48=100·12 Berzelius.
2. "	13·40	56·47	5·60	—	—	—	20·00=98·67 Pisani.

Pyr., etc.—Same as for torbernite, but no reaction for copper.

Obs.—Autunite is found usually with other ores of uranium, associated with silver, tin, and iron ores. Occurs in the Siebengebirge, in the hornstone of a trachytic range; at Johanngeorgenstadt and Eibenstock; at Lake Onega, Wolf Island, Russia; near Limoges, and at St. Symphorien near Autun; formerly at South Basset, Wheal Edwards, and near St. Day, England. Occurs sparingly at the Middletown (Ct.) feldspar quarry, associated with columbite and albite, in minute tabular crystals and thin scales, of light green and lemon-yellow colors; also in minute crystals at Chesterfield, Mass., on the quartz or albite, and sometimes in the red centres of tourmalines, and at Acworth, N. H., straw-yellow and light green; also in a gneiss quarry on the Schuylkill, near Philadelphia, about ½ m. above the suspension bridge.

Descloizeaux makes autunite to differ from torbernite (Ann. d. M., V. xiv. 1857) in being optically biaxial, and therefore orthorhombic; and the planes 2 of the latter thus become 2-ī and 2-ĭ, as they incline unequally to the base. The angles are still very closely the same, the pyramidal 95° 52′, being in torbernite 96° 6′, Kokscharof; 95° 52′, Hessenberg; 95° 46′, Haidinger. The species are at least closely isomorphous.

Berzelius calls the uranite of Cornwall and that of Autun, respectively, *chalcolite* and *uranite*, in his article announcing the composition, in Jahresb., iv. 146, 147, 1823; and the special application of *uranite* to this species dates from that time. Yet, in order to avoid confusion from the double use of the name, it is better to adopt for the species the name of *autunite*, from one of its noted localities.

Fritzscheite *Breith.*, B. H. Ztg., xxiv. 302, 1865. A mineral much resembling uranite in its four-sided quadratic (or nearly so) tables, with a perfect basal cleavage; with H.=2–2·5; G.=3·504?; vitreous to pearly in lustre; reddish-brown to hyacinth-red in color and streak; translucent; affording Fritzsche (l. c.) reactions for oxyd of uranium, protoxyd of manganese, vanadic acid, phosphoric acid, and water. The red color is attributed to the manganese, and it is considered a mangan-uranite containing some vanadic acid. It occurs with crystals of autunite and torbernite at Neuhammer, near Neudeck in Bohemia, in a hematite mine; at Johanngeorgenstadt, of fine red color, with torbernite. Red crystals in groups, supposed to be this mineral, have been observed on specimens of uranite from Autun, and from Steinig, near Elsterberg, in Saxon Voigtland. May it be an altered uranite?

574. AMPHITHALITE. Amfithalit *Igelström*, Œfv. Ak. Stockh., 1866, 93, B. H. Ztg., xxv. 309, 1866.

Massive. H.=6. Color milk-white. Subtranslucent.

O. ratio for $\dot{R}$, $\overset{\cdot\cdot\cdot}{\bar{R}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{P}}$, $\dot{H}$=1 : 10·25 : 7·5 : 5. Analysis: Igelström (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{P}}$	$\overset{\cdot\cdot\cdot}{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$
30·06	48·50	1·55	5·76	12·47=93·34 Igelström.

B.B. infusible. Insoluble in acids. Occurs in the quartzite of Horrsjöberg, Wermland, with lazulite, rutile, and cyanite. Named from αμφιθαλής, *becrowned*, since it usually occurs surrounded by other beautiful minerals, though unattractive itself.

574A. *Hydrous Phosphate of Alumina and Lime* Damour (L'Institut, 1853, 78). Compact, of a pale or dark brick-red color. Scratches glass feebly. G.=3·194. Supposed by Damour to be a hydrophosphate of alumina and lime. B.B. in a tube gives considerable water; and in a platinum crucible at a red heat loses 12·70 p. c. of water. Found in rolled pebbles with the diamond sand of Bahia.

574B. *Cupreous Phosphate of Alumina.* Domeyko (Min., 2d ed. 425) describes a mineral from San Lorenzo de la Ligna, Chili, occurring in a decomposed feldspathic rock, giving on analysis $\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{P}}$ 17·7, $\dddot{\mathrm{Si}}$ 7·6, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{Al}}}$ 46·3, $\dot{\mathrm{Cu}}$ 6·3, $\overset{\cdot\cdot\cdot}{\bar{\mathrm{Fe}}}$ 3·3, $\dot{\mathrm{H}}$ 18·8=100. Its color is a pale turquois-blue; structure compact, homogeneous, and so soft as to be scratched by the nail.

575. SPHÆRITE. Sphærit *v. Zepharovich*, Ber. Ak. Wien, lvi. 1867.

In globular concretions with a drusy faceted surface, without a distinct fibrous or concentric structure. Cleavage distinct in one direction.

H.=4. G.=2·536. Lustre greasy-vitreous, glimmering. Color light gray, more or less reddish or bluish, the red color from mixture with hematite. Translucent.

Comp.—O. ratio for $\dddot{\overline{Al}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{P}$, $\dot{H}$=3 : 2 : 3½; $\dddot{\overline{Al}}{}^5\,\overset{\cdot\cdot\cdot\cdot\cdot}{P}{}^2+16\,\dot{H}$=Phosphoric acid 26·1, alumina 47·4 water 26·5=100. Analyses: A, Boricky (l. c.); B, same, with $\ddot{Si}$, $\dot{Ca}$, $\dot{Mg}$, and some $\overset{\cdot\cdot\cdot\cdot\cdot}{P}$ (for these bases) excluded:

	$\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$\dddot{\overline{Al}}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{H}$	$\ddot{Si}$
A.	(½) 28·58	42·36	2·60	1·41	24·03	0·87=99·85.
B.	26·80	46·71	—	—	26·49	—=100.

Pyr., etc.—Yields water. B.B. is infusible, and colors the flame bluish-green. With cobalt solution a fine blue.

Obs.—Occurs lining cavities or seams in hematite, at Zajecov, Bohemia, in Lower Silurian schists, along with wavellite.

Alt.—Becomes opaque white, dull, and earthy by alteration.

576. BORICKITE. Delvauxene (fr. Leoben) *v. Hauer*, Jahrb. G. Reichs. 1854, 68; (fr. Nenacovic) *Boricky*, Nat. ZS. Lotos, March, 1867. Borickite *Dana*.

Reniform massive. Compact, without cleavage.

H.=3·5. G.=2·696–2·707. Lustre weak waxy. Color reddish-brown Streak the same as color. Opaque.

Comp.—O. ratio for $\dot{R}+\dddot{\overline{R}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{P}$, $\dot{H}$=3 : 2 : 3, with $\dot{R}$: $\dddot{\overline{R}}$=1 : 7; $\dot{R}$=$\dot{Ca}$, $\dddot{\overline{R}}$=$\dddot{\overline{Fe}}$; $(\dddot{\overline{Fe}}, \dot{Ca}{}^3)^5\,\overset{\cdot\cdot\cdot\cdot\cdot}{P}+15\,\dot{H}$.

Analyses: 1, v. Hauer (l. c.); 2, Boricky (l. c.):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{P}$	$\dddot{\overline{Fe}}$	$\dot{Mg}$	$\dot{Ca}$	$\dot{H}$
1. Leoben	(½) 20·49	52·29	—	8·16	19·06=100 Hauer.
2. Nenacovic	19·35	52·99	0·41	7·29	19·96=100 Boricky.

Pyr., etc.—Yields water. B.B. fuses easily to a black mass. Soluble in muriatic acid.

Obs.—From Leoben in Styria, and in a Lower Silurian schist at Nenacovic in Bohemia.

PHOSPHATES OR ARSENATES, COMBINED WITH SULPHATES.

580. DIADOCHITE. Diadochit *Breith.*, J. pr. Ch., x. 503, 1837. Phosphoreisensinter *Ramm*

Reniform or stalactitic; structure curved lamellar.

H.=3. G.=2·035. Lustre resinous, inclining to vitreous. Color yellow or yellowish-brown. Streak uncolored. Fragile; fracture conchoidal.

Comp.—$\dddot{\overline{Fe}}{}^3\,\overset{\cdot\cdot\cdot\cdot\cdot}{P}{}^2+2\,\dddot{\overline{Fe}}\,\dddot{S}{}^3+32\,\dot{H}$=Phosphoric acid 14·3, sulphuric acid 16·2, sesquioxyd of iron 40·4, water 29·1=100. Analysis by Plattner (Ramm. 1st Suppl., 45):

$\overset{\cdot\cdot\cdot\cdot\cdot}{P}$ 14·811 $\dddot{S}$ 15·145 $\dddot{\overline{Fe}}$ 39·690 $\dot{H}$ 30·344=100.

Near iron sinter (pitticite), with phosphoric acid in place of arsenic acid.

Pyr., etc.—Yields much water in the closed tube, and swells up, becoming lustreless and opaque yellow; when ignited gives off sulphuric acid. B.B. in the forceps swells up and falls to powder, but carefully ignited fuses easily to a grayish-black slag, and colors the flame bluish-green. On charcoal affords a steel-gray magnetic globule. With soda affords metallic particles, and gives a sulphid which blackens silver. With borax and salt of phosphorus reacts for iron. Soluble in muriatic acid.

Obs.—From alum-slate near Gräfenthal and Saalfeld in Thuringia.

Named from διάδοχος, *a successor*, on the supposition that it is an iron sinter, in which phosphoric acid has replaced the arsenic acid.

581. PITTICITE. Eisenpecherz *Karsten* [not *Wern.*], Tab., 66, 98, 1808. Fer oxydé resinite *Haüy*, Tabl., 98, 1809. Pittizit *Hausm.*, Handb., 285, 1813. Eisensinter *Wern.*, Hoffm. Min., iii. b, 302, 1816; iv. b, 141, 1817; fr. Freiesleben G. Arb., v. 74, 261. Arseneisensinter *Germ.* Pitchy Iron Ore. Diarsenate of Iron. Sideretine *Beud.*, Tr., ii. 609, 1832 [not *Pittizite* Beud., p. 484]. Pitticit *Hausm.*, Handb., 1022, 1847.

Reniform and massive.

H.=2—3. G.=2·2—2·5. Lustre vitreous, sometimes greasy. Color yellowish and reddish-brown, blood-red and white. Streak yellow—white. Translucent—opaque.

Comp.—Analyses afford varying results. O. ratio for $\dddot{\rm R}$, $\dddot{\rm S}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}$, $\dot{\rm H}$, from Stromeyer's analysis, approximately 6 : 3 : 5 : 15, whence $\dddot{\rm Fe}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}+\dddot{\rm Fe}\,\dddot{\rm S}+15\,\dot{\rm H}$=Arsenic acid 25·6, sulphuric acid 8·9, oxyd of iron 35·6, water 29·9=100; from the Schwarzenberg ore (No. 6) 12 : 9 : 10 : 24; whence Rammelsberg deduces $\dddot{\rm Fe}^3\,\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}^2+\dddot{\rm Fe}\,\dddot{\rm S}^3+24\,\dot{\rm H}$; perhaps $2\,\dddot{\rm Fe}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}+3\,(\dddot{\rm Fe},\dot{\rm H}^3)\,\dddot{\rm S}+21\,\dot{\rm H}$; or $2\,\dddot{\rm Fe}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}+\dddot{\rm Fe}\,\dddot{\rm S}^3+21\,\dot{\rm H}+\dddot{\rm Fe}\,\dot{\rm H}^3$;=Arsenic acid 26·0, sulphuric acid 13·6, oxyd of iron 36·1, water 24·3 =100. 1, Stromeyer (Gilb. Ann., lxi. 181); 2, Laugier (Ann. Ch., xxx. 325); 3, Kersten (Schw. J., liii. 176); 4, 5, Rammelsberg (Pogg., lxii. 139); 6, id. (5th Suppl., 102):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}$	$\dddot{\rm S}$	$\dddot{\rm Fe}$	$\dddot{\rm Mn}$	$\dot{\rm H}$
1. Freiberg	26·06	10·14	33·10	0·64	29·26=99·09 Stromeyer.
2. "	20	14	35	*tr.*	30=99 Laugier.
3. "	30·25	——	40·45	——	28·50=99·20 Kersten.
4. Seiglitzstollen	24·67	5·20	54·66	——	15·47=100 Rammelsberg.
5. "	28·45	4·36	58·00	——	12·59=100 Rammelsberg.
6. Schwarzenberg	26·70	13·91	34·85	——	24·54=100 Rammelsberg.

Pyr., etc.—In the closed tube yields water, and at a high heat gives off sulphurous acid. In the forceps and on charcoal like scorodite. With soda on charcoal gives arsenical fumes and a sulphid which blackens silver.

Obs.—Occurs in old mines near Freiberg and Schneeberg in Saxony, and elsewhere. An ore on Hopkins's farm near Edenville, N. Y., is referred by Beck to this species.

For an iron-sinter without the sulphate, see under SCORODITE.

582. BEUDANTITE. *Levy*, Ann. Phil., II. xi. 194, 1826.

Rhombohedral. $R \wedge R$=91° 18′ (mean), Dauber. Occurring planes: O, 5, 10, R, –1, –2, $-\frac{5}{2}$, –4, –5; crystals modified acute rhombohedrons. Cleavage: basal, easy. Basal plane (O) flat, dull; R bright, curved.

H.=3·5—4·5. G.=4—4·3. Lustre vitreous. Subadamantine, resinous. Color dark to clear olive-green, yellowish-green, black, brown. Streak greenish-gray to yellow. Usually opaque, rarely transparent.

Var.—1. A mineral containing phosphoric acid, with little or no arsenic; the mineral from Cork and Dernbach. 2. Containing arsenic acid, with little phosphoric acid; mineral from Horhausen.

$R \wedge R$, in crystals from Cork, 91° 18′, Dauber; from Dernbach, 91° 9′, Dauber; from Horhausen, 92° 30′, Levy; 91° 48′, Dauber. The Cork crystals are black, brown, or green and opaque; G. =4·295, green, Ramm.; those of Dernbach, olive-green to yellowish-green, sometimes transparent, with H.=3·5, G.=4·0018, Sandberger. The Horhausen mineral was the *original* beudantite.

Comp.—Results varying much. Analyses: 1, Sandberger (Pogg., c. 611); 2, Rammelsberg (Jb., 581); 3, 4, Percy (Phil. Mag., II. xxxvii. 161); 5, Sandberger (l. c.):

A. Phosphatic variety.

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\rm P}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\rm As}$	$\dddot{\rm S}$	$\dddot{\rm Fe}$	$\dot{\rm Pb}$	$\dot{\rm Cu}$	$\dot{\rm H}$
1. Dernbach ($\frac{1}{2}$)	13·22	*tr.*	4·61	44·11	26·92	*tr.*	11·44 Sandberger.
2. Cork, *green* ($\frac{1}{2}$)	8·97	0·24	13·76	40·69	24·05	2·45	9·77 Rammelsberg.

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{s}$	$\dddot{\mathrm{S}}$	$\dddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{P}}\mathrm{b}$	$\dot{\mathrm{H}}$
3. Horhausen	1·46	9·68	12·81	42·46	24·47	8·49=98·87 Percy.
4. "	*und.*	13·60	12·35	37·65	29·52	8·49=101·61 Percy.
5. "	2·79	12·51	1·70	47·28	23·43	[12·29]=100 Sandberger.

Pyr., etc.—Heated yields water. B.B., alone, the Cork crystals are infusible, but yield on charcoal fumes of sulphurous acid and afford a yellow slag, and with soda a kernel of lead; the Dernbach fuse easily on charcoal with intumescence to a globule of lead, mixed with a black hepatic slag; the Horhausen also fuse easily, affording a gray slaggy globule, and after long blowing the odor of arsenic.

Obs.—Occurs at the Glendore iron mine, near Cork, with quartz and limonite; at Dernbach, near Montabaur, in Nassau; at Horhausen, in Nassau, on limonite.

583. LINDACKERITE. Lindackerit *J. F. Vogl*, Jahrb. G. Reichs., iv. 552, 1853.

Orthorhombic. In oblong rhombohedral tables, grouped in rosettes, and in reniform masses.

H.=2–2·5. Lustre vitreous. Color verdigris- to apple-green. Streak paler to white.

Comp.—$2\,\dot{\mathrm{C}}\mathrm{u}^3\,\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{s}+\dot{\mathrm{N}}\mathrm{i}^3\,\dddot{\mathrm{S}}+7\,\dot{\mathrm{H}}$, Lindacker, who obtained (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}}\mathrm{s}$ 28·58 $\dddot{\mathrm{S}}$ 6·44 $\dot{\mathrm{C}}\mathrm{u}$ 36·34 $\dot{\mathrm{N}}\mathrm{i}$ 16·15 $\dot{\mathrm{F}}\mathrm{e}$ 2·90 $\dot{\mathrm{H}}$ 9·32=99·78.

Pyr., etc.—B.B. on charcoal gives alliaceous fumes, and fuses to a black bead. With borax and salt of phosphorus a copper reaction. Soluble after long heating in muriatic acid, the solution giving a yellowish-brown precipitate with sulphuretted hydrogen.

Obs.—From Joachimsthal.

584. SVANBERGITE. Svanbergit *Igelström*, Œfv. Ak. Stockh., 1854, 156.

Rhombohedral. $R\wedge R=90°\ 35'$; $R\wedge 4R$ (occurring planes)$=154°\ 30'$, Dauber; $R\wedge R=87\tfrac{1}{2}°$ to 88°, Breith., with other rhombohedrons of 95° 16′ and 82° 26′.

H.=5. G.=3·30; 2·571, Breith.; 3·29, Blomstrand. Lustre vitreous to adamantine. Color honey-yellow to yellowish-brown, reddish-brown, and rose-red. Streak reddish or colorless. Subtransparent.

Comp.—Analyses: 1, Igelström (l. c., and J. pr. Ch., lxiv. 252); 2, C. W. Blomstrand (priv. contrib., Dec. 8, 1867):

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}}$	$\dddot{\mathrm{S}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{P}}\mathrm{b}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{H}}$	Cl
1. Wermland	17·80	17·32	37·84	1·40	——	——	——	6·00	12·84	6·80	*tr.* Igelstr.
2. Westana	15·70	15·97	34·95	0·78	*tr.*	3·82	0·24	16·59	——	12·21	—=100·21 Bl.

Blomstrand's analysis gives the O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\dddot{\mathrm{S}}$, $\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}}$, $\dot{\mathrm{H}}=3:9:5\tfrac{1}{2}:5:6$; taking it at $3:9:6:5:6$, it affords the formula $(\tfrac{1}{2}\,\dot{\mathrm{C}}\mathrm{a}^3+\tfrac{1}{2}\,\dddot{\bar{\mathrm{A}}}\mathrm{l})^2\,\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}}+2\,\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dddot{\mathrm{S}}+6\,\dot{\mathrm{H}}$=Phosphoric acid 16·0, sulphuric acid 18·0, alumina 34·9, lime 18·9, water 12·2=100. Taking the ratio at $3:9:5:5:6$, it corresponds to the formula $3\,(\tfrac{1}{2}\,\dot{\mathrm{C}}\mathrm{a}^3+\tfrac{1}{2}\,\dddot{\bar{\mathrm{A}}}\mathrm{l})^2\,\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}}+5\,\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dddot{\mathrm{S}}+\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dot{\mathrm{H}}^3+15\,\dot{\mathrm{H}}$.

Igelström's analysis affords approximately $3:9:5:5:3$, and the same formula as the last, excepting $6\,\dot{\mathrm{H}}$ in place of $15\,\dot{\mathrm{H}}$. But it differs widely in the protoxyds, it containing much soda (determined by the loss?), and comparatively little lime.

Pyr., etc.—In a tube acid water. B.B. on coal fuses only on the thinnest edges; with soda in reducing flame a red hepatic mass, which becomes green with water and yields sulphuretted hydrogen with dilute acid. With borax, an iron-colored glass. With cobalt solution a fine blue. But little acted upon by acids.

Obs.—From Horrsjöberg in Wermland, occurring with lazulite, cyanite, pyrophyllite, damourite, hematite, etc. It is near beudantite in crystallization.

585. FICINITE *Bernhardi*, Worterb. d. Nat. gesch., iv. 574, Weimar, 1827. Glocker's Min., 556 1831; *Kenngott*, Min. Not., No. xi, and Ueb. 1854, 441, 1859, 32.

Monoclinic, with one perfect cleavage, and a second inclined 129° to the other, both parallel to the orthodiagonal.

H.=5–5·5. G.=3·4–3·53. Lustre waxy or pearly, weak. Color black. Subtranslucent.

Analysis by Ficinus (l. c.): $\ddot{\bar{\mathrm{P}}}$ 12·82, $\dddot{\mathrm{S}}$ 4·07, $\dot{\mathrm{F}}\mathrm{e}$ 58·85, $\dot{\mathrm{M}}\mathrm{n}$ 6·82, $\dot{\mathrm{C}}\mathrm{a}$ 0·17, $\ddot{\mathrm{S}}\mathrm{i}$ 0·17, $\dot{\bar{\mathrm{H}}}$ 16·87. B.B. fuses to a semimetallic slag, which is magnetic. In acids hardly attacked.

Found at Bodenmais, with garnet, iolite, etc. Also reported as occurring at the Gottesgab mine near Bodenmais, in crystals.

HYDROUS ANTIMONATES.

586. BINDHEIMITE. Blei-Niere (fr. Nertschinsk) *Karst.*, Tab., 50, 77, 78, 1800 (citing anal. by *Bindheim*, Schrift. Ges. Nat. Fr. Berlin, x. 374, 1792). Antimonate of Lead. Antimonbleispath, Antimonsaures Bleioxyd, *Germ.* Stibiogalenit *Glock.*, Syn., 257, 1847. Bleinerite *Nicol*, Min., 383, 1849.

Amorphous, reniform, or spheroidal; also earthy or incrusting. Structure sometimes curved lamellar.

H.=4. G.=4·60–4·76, Siberia, Hermann; 5·05, white, Cornwall, Heddle; 4·707, brown, ib., Heddle. Lustre resinous, dull, or earthy. Color white, gray, brownish, yellowish. Streak white to grayish or yellowish. Opaque to translucent.

Comp.—$\dot{\mathrm{P}}\mathrm{b}^3\ddot{\bar{\mathrm{S}}}\mathrm{b}+4\dot{\bar{\mathrm{H}}}$, Siberian mineral, Hermann; $\dot{\mathrm{P}}\mathrm{b}^3\ddot{\bar{\mathrm{S}}}\mathrm{b}+2\frac{1}{2}\dot{\bar{\mathrm{H}}}$, Horhausen, Ramm.; $\dot{\mathrm{P}}\mathrm{b}\,\ddot{\bar{\mathrm{S}}}\mathrm{b}^2+10\dot{\bar{\mathrm{H}}}$, Cornwall, Heddle, anal. 4, 6; the true nature not fully understood.

Analyses: 1, Hermann (J. pr. Ch., xxxiv. 179); 2, C. Stamm (Pogg., c. 618); 3–5, Heddle (Phil. Mag., IV. xii. 126, Greg & Letts. Min., 373); 6, Percy (ib.):

	$\ddot{\bar{\mathrm{S}}}\mathrm{b}$	$\dot{\mathrm{P}}\mathrm{b}$	$\dot{\bar{\mathrm{H}}}$	$\dddot{\bar{\mathrm{F}}}\mathrm{e}$	$\dot{\mathrm{C}}\mathrm{a}$	$\ddot{\bar{\mathrm{A}}}\mathrm{s}$
1. Nertschinsk	31·71	61·38	6·46	—	—	—=100 Hermann.
2. Horhausen	41·13	48·34	5·43	3·35	*tr.*	*tr.*, $\dot{\mathrm{C}}\mathrm{u}$ 0·84=99·59 Stamm.
3. Cornwall, *white*	42·22	47·04	11·50	—	—	—=100·76 Heddle.
4. " "	42·44	46·68	11·98	—	—	—=101·10 Heddle.
5. " *brown*	46·70	43·94	6·46	1·44	1·34	*tr.*=99·88 Heddle.
6. "	47·36	40·73	11·91	—	—	—=100 Percy.

Pfaff early found in the Nertschinsk mineral (Schw. J., xxvii. 1) $\ddot{\bar{\mathrm{S}}}\mathrm{b}$ 43·96, $\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 16·42, $\dot{\mathrm{P}}\mathrm{b}$ 33·10, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 0·24, $\dot{\mathrm{C}}\mathrm{u}$ 3·24, $\ddot{\mathrm{S}}\mathrm{i}$ 2·34, $\dddot{\mathrm{S}}$ 0·62, Fe, Mn, etc., 3·32=103·28. Bindheim (l. c.) made it to contain $\ddot{\bar{\mathrm{A}}}\mathrm{s}$ 25, $\dot{\mathrm{P}}\mathrm{b}$ 35, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 14, $\dot{\bar{\mathrm{H}}}$ 10, $\ddot{\mathrm{S}}\mathrm{i}$, $\dddot{\bar{\mathrm{A}}}\mathrm{l}$ 9, Ag 1·15=95·15.

Pyr., etc.—In the closed tube gives off water. B.B. on charcoal reduced to a metallic globule of antimony and lead, coating the charcoal white at some distance from the assay, and yellow nearer to it.

Obs.—A result of the decomposition of other antimonial ores.

From Nertschinsk in Siberia; Horhausen; near Endellion in Cornwall, with jamesonite, from which it is derived.

Bleinierite is German for *Lead-kidney-ite!* and *Stibiogalenite* implies the presence of galena or sulphid of lead; hence the substitute above after the earliest analyst of the species.

B. NITRATES.

590. NITRE	$\dot{\mathrm{K}}\ddot{\bar{\mathrm{N}}}$	$\mathrm{N}\Theta_2\vert\Theta\vert\mathrm{K}$
591. SODA NITRE	$\dot{\mathrm{N}}\mathrm{a}\ddot{\bar{\mathrm{N}}}$	$\mathrm{N}\Theta_2\vert\Theta\vert\mathrm{Na}$
592. NITROCALCITE	$\dot{\mathrm{C}}\mathrm{a}\ddot{\bar{\mathrm{N}}}+\dot{\bar{\mathrm{H}}}$	$(\mathrm{N}\Theta_2)_2\vert\Theta_2\vert\bar{\mathrm{C}}\mathrm{a}+aq$
593. NITROMAGNESITE	$\dot{\mathrm{M}}\mathrm{g}\ddot{\bar{\mathrm{N}}}+n\dot{\bar{\mathrm{H}}}$	$(\mathrm{N}\Theta_2)_2\vert\Theta_2\vert\bar{\mathrm{M}}\mathrm{g}+n\,aq$

590. NITRE. Nitrate of Potash. Saltpetre. Salpeter *Germ.* Kalisalpeter *Hausm.*, Handb. 849, 1813. Potasse nitratée.

Orthorhombic. $I \wedge I = 118° 50'$, $O \wedge 1\text{-}\bar{i} = 130° 8'$; $a : b : c = 1{\cdot}1861 : 1 : 1{\cdot}692$. $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, top, $= 109° 57'$, $2\text{-}\bar{i} \wedge 2\text{-}\bar{i}$, ib., $= 71°$ at 19° C., and 71° 44′ at 100° C., B. and M. Generally in thin crusts, silky tufts, and delicate acicular crystallizations.

H.=2. G.=1·937. Lustre vitreous. Streak and color white. Subtransparent. Brittle. Taste saline and cooling.

Comp.—$\dot{K}\ddot{N}$=Nitric acid 53·4, potash 46·6=100. Klaproth obtained for an African specimen (Beitr., i. 317) Nitrate of potash 42·55, sulphate of lime 25·54, chlorid of calcium 0·20, carbonate of lime 30·40=98·69.

Pyr., etc.—Deflagrates vividly on burning coals, and detonates with combustible substances. Colors the flame violet (potash). Dissolves easily in water; not altered by exposure.

Obs.—Found generally in minute needle-form crystals, and crusts on the surface of the earth, on walls, rocks, etc. It forms abundantly in certain soils in Spain, Egypt, and Persia, especially during hot weather succeeding rains. Also manufactured from soils where other nitrates (nitrate of lime or soda) form in a similar manner, and beds called *nitriéries* are arranged for this purpose in France, Germany, Sweden, Hungary, and other countries. Refuse animal matter, also, petrified in calcareous soils, gives rise to the nitrate of lime. Old plaster, lixiviated, affords about 5 p. c. of nitre. In India it is obtained in large quantities for the arts.

Nitre requires for its formation dry air and long periods without rain; the potash comes mainly from the debris of feldspathic rocks in the soil. The oxydation of the nitrogen of the air is promoted by organic matters; hence the nitre is generally associated with animal decomposed organic substances. A nitre crust from the vicinity of Constantine, Algeria, afforded $\dot{K}\ddot{N}$ 86·00, $\dot{C}a\ddot{N}$ and $\dot{M}g\ddot{N}$ 3·04, Na Cl 6·00, $\dot{H}$ 3·50, insol. etc. 1·50=100, Boussingault.

In Madison Co., Kentucky, it is found scattered through the loose earth covering the bottom of a large cave. Also in other caverns in the Mississippi valley. Those of Tennessee, along the limestone slopes and in the gorges of the Cumberland table-land, afford it abundantly.

Nitre, according to Frankenheim, is dimorphous like carbonate of lime; one form *prismatic* (aragonite-like), the other *rhombohedral* (calcite-like). The prismatic is the normal one between −10° C. and 30° C.; and between these temperatures the rhombohedral is easily transformed into the prismatic through the presence of some foreign substance. Above 30° the rhombohedral is the normal one, the prismatic here changing to it, and retaking again its form on a diminution of temperature (Pogg., xcii. 354).

591. SODA NITRE. Soude nitratée native *M. de Rivero*, Ann. d. M., vi. 596, 1821. Nitrate of Soda. Soda Nitre. Nitre cubique. Natron-Salpeter *Leonh.*, Handb., 246, 1826. Nitratin *Haid.*, Handb., 1845.

Rhombohedral. $R \wedge R = 106° 33'$; $a = 0{\cdot}8276$. Cleavage: rhombohedral, perfect. In efflorescences; also massive, granular.

H.=1·5–2. G.=2·09–2·29; 2·290, Tarapaca, Hayes. Lustre vitreous. Color white; also reddish-brown, gray, and lemon-yellow. Transparent. Rather sectile. Fracture indistinctly conchoidal. Taste cooling. Crystals strongly doubly refracting.

Comp.—$\dot{N}a\ddot{N}$=Nitric acid 63·5, soda 36·5=100. Hochstetter obtained from the Chilian mineral (v. Leonh., 1846, 335) $\dot{N}a\ddot{N}$ 94·291, Na Cl 1·990, $\dot{K}\dddot{S}$ 0·233, $\dot{K}\ddot{N}$ 0·425, $\dot{M}g\ddot{N}$ 0·558, insol. 0·313, $\dot{H}$ 1·993.

Pyr., etc.—Deflagrates on charcoal with less violence than nitre, causing a yellow light, and also deliquesces. Colors the flame intensely yellow. Dissolves in three parts of water at 60° F.

Obs.—In the district of Tarapaca, northern Chili, the dry pampa for 40 leagues, at a height of 3,300 feet above the sea, is covered with beds of this salt several feet in thickness, along with gypsum, common salt, glauber salt, and remains of recent shells, the last indicating the former presence of the sea. De Rivero, l. c.; J. H. Blake, Am. J. Sci., xxxix. 373, 1840.

A. A. Hayes obtained from masses collected by Mr. Blake, Nitrate of soda 64·98, sulphate of soda 3·00, common salt 28·69, iodids 0·63, shells and marl 2·60=99·90.

In 1837, 150,900 quintals of this salt refined were shipped from Yquique; in 1866, 1,[illegible]00,000 quintals. It is used for the manufacture of nitric acid and nitre.

$O \wedge \frac{1}{2}$-2 in soda nitre equals nearly $O \wedge \frac{1}{2}$ in apatite.

92. NITROCALCITE. Kalksalpeter *Haus.*, Handb., 1813. Nitrate of lime. Chaux nitratée. Nitrocalcite *Shep.*, Min., ii. 84, 1835. Calcinitre *Huot*, Min., ii. 480, 1841.

In efflorescent silken tufts and masses. Color white or gray. Taste sharp and bitter.

Comp.—$\dot{C}a\,\ddot{\ddot{N}}+\dot{H}$=Nitric acid 59·4, lime 30·7, water 9·9=100.

Pyr., etc.—On burning coals it slowly fuses with a slight detonation, and dries. Very deliquescent before, but not after, being desiccated by heat.

Obs.—It occurs in silky efflorescences, in many limestone caverns, as those of Kentucky. The salt forms in covered spots of earth, where the soil is calcareous, and is extensively used in the manufacture of saltpetre. According to Hausmann, a large part of the so-called nitre in nature is this salt.

593. NITROMAGNESITE. Nitrate of Magnesia *Beud.*, Tr., ii. 384, 1832. Nitromagnesite *Shep.*, Min., ii. 85, 1835. Magnesinitre *Huot*, Min., ii. 481, 1841. Magnésie nitratée. Magnesiasalpeter.

In efflorescences. White. Taste bitter.

Comp.—The salt contains, when pure and anhydrous, nitric acid 72·3, magnesia 27·7.

Obs.—From limestone caves, along with nitrocalcite.

The existence of this species as a natural product has not yet been clearly made out.

4. BORATES.

Boric acid occurs in but few minerals; viz., Datolite, Danburite, Axinite, and Tourmaline, with the following. It is a remarkable fact that in all of them, as far as known, the crystallization is either hemihedral or oblique. Boracite and Rhodizite are hemihedral isometric; Tourmaline hemihedral rhombohedral; Datolite is monoclinic; while Danburite and Axinite are triclinic. In Tourmaline and Axinite boric acid acts the part of a base.

ARRANGEMENT OF THE SPECIES.

1. O. ratio for bases and acid 1 : 1.

594. SASSOLITE	$\dot{H}^3\dddot{B}$	$B\|\Theta_3\|H_3$
595. SZAIBELYITE	$(\frac{4}{5}\dot{M}g+\frac{1}{5}\dot{H})^3\dddot{B}+\frac{1}{5}\dot{H}$	$B_2\|\Theta_6\|(\frac{1}{5}H_2+\frac{4}{5}Mg)_3+\frac{1}{5}$ aq
596. HYDROBORACITE	$(\frac{1}{2}(\dot{C}a,\dot{M}g)^3+\frac{1}{2}\dot{H}^3)\dddot{B}$	$B_2\|\Theta_6\|(\frac{1}{2}H_2+\frac{1}{2}(Ca,Mg))_3$

2. O. ratio for bases and acid 1 : 4.

597. BORACITE	$\dot{M}g^3\dddot{B}^4+\frac{1}{3}Mg\,Cl$	$B_2\Theta_6\|\Theta_6\|Mg_3+\frac{1}{3}Mg\,Cl_2$
598. RHODIZITE		

3. O. ratio for bases and acid 1 : 6 or 1 : 12; part or all of the water probably basic, and thus rationally, 1 : 3.

599. **Borax**	$(\frac{1}{2}\dot{Na}+\frac{1}{2}\dot{H})\ddot{B}+4\frac{1}{2}\dot{H}$	$B\Theta\|\Theta\|(\frac{1}{2}H+\frac{1}{2}Na)+2\frac{1}{4}aq$
600. **Bechilite**	$(\frac{1}{2}\dot{Ca}+\frac{1}{2}\dot{H})\ddot{B}+1\frac{1}{2}\dot{H}$	$(B\Theta)_2\|\Theta_2\|(\frac{1}{2}H_2+\frac{1}{2}\Theta a)+1\frac{1}{2}aq$
601. **Howlite**	$(\frac{1}{2}\dot{Ca}+\frac{1}{2}\dot{H})\ddot{B}+\frac{3}{4}\dot{H}$	$(B\Theta)_2\|\Theta_2\|(\frac{1}{2}H_2+\frac{1}{2}\Theta a)+\frac{3}{4}aq$
	$+\frac{1}{6}[(\frac{1}{3}\dot{Ca}^3+\frac{1}{3}\ddot{B})^2\ddot{Si}^3]$	$+Q$
602. **Ulexite**	$(\frac{1}{6}\dot{Na}+\frac{2}{6}\dot{Ca}+\frac{3}{6}\dot{H})\ddot{B}+2\frac{1}{4}\dot{H}$	$(B\Theta)_2\|\Theta_2\|(\frac{3}{6}H_2+\frac{1}{6}Na_2+\frac{2}{6}\Theta a)+2\frac{1}{4}aq$
603. **Cryptomorphite**	$(\frac{1}{5}\dot{Na}+\frac{3}{5}\dot{Ca}+\frac{1}{5}\dot{H})\ddot{B}+\dot{H}$	$(B\Theta)_2\|\Theta_2\|(\frac{1}{5}H_2+\frac{1}{5}Na_2+\frac{3}{5}\Theta a)+aq$
604. **Larderellite**	$(\frac{1}{4}N\,H^4O+\frac{3}{4}\dot{H})\ddot{B}+\frac{1}{2}\dot{H}$	$B\Theta\|\Theta\|\frac{3}{4}H+\frac{1}{4}Am)+\frac{1}{2}aq$
605. **Lagonite**	$\ddot{Fe}\ddot{B}^3+3\dot{H}$	$(B\Theta)_2\|\Theta_2\|\beta Fe+aq$

Appendix.—606. **Warwickite** $\ddot{B}, \ddot{Ti}, \dot{Mg}, \ddot{Fe}$

594. SASSOLITE. Sale sedativo naturale *U. F. Hoefer*, Memoria, Firenze, 1778; *Mascagni*, Mem. Soc. Ital., viii. 487. Native Sedative Salt. Acidum boracis, *vulgo* Sal sedativum, *Bergm.*, Sciagr., 1782. Native Boracic Acid *Kirw.*, 1796. Sassolin *Karst.*, Tab., 40, 75, 1800. Acide boracique *Fr.* Boric Acid.

Triclinic. $I \wedge I'=118° 30'$, $O \wedge I=95° 3'$, $O \wedge I'=80° 33'$, B. & M. Twins: composition-face O. Cleavage: basal very perfect. Usually in small scales, apparently six-sided tables, and also in stalactitic forms, composed of small scales.

H.=1. G.=1·48. Lustre pearly. Color white, except when tinged yellow by sulphur; sometimes gray. Feel smooth and unctuous. Taste acidulous, and slightly saline and bitter.

Comp.—$\dot{H}^3\ddot{B}$=Boric acid 56·4, water 43·6=100. The native stalactitic salt, according to Klaproth (Beitr., iii. 97), contains, mechanically mixed, sulphate of magnesia and iron, sulphate of lime, silica, carbonate of lime, and alumina.

Pyr., etc.—In the closed tube gives water. B.B. on platinum wire fuses to a clear glass and tinges the flame yellowish-green. Some specimens react for sulphur or ammonia in the closed tube. Soluble in water and alcohol. Dissolves in 2·97 parts of water at 100° C., and 10·7 parts at 50° C.

Obs.—This long known compound, the *Sal sedativum Hombergii*, was first detected in nature by Hoefer in the waters of the Tuscan lagoons of Monte Rotondo and Castelnuovo, and afterward in the solid state at Sasso by Mascagni. The hot vapors of the lagoons consist largely of boric acid. To collect it the vapors are made to pass through water, which absorbs the boric acid; the waters are then evaporated by means of the steam from the springs. They yield seven to eight thousand pounds troy per day. These lagoons spread over a surface of about 30 miles; and in the distance, clouds of vapor are seen rising in large volumes among the mountains. The crude borax contains 20 p. c. or more of impurities, among which Wittstein and Payen found 13·7 p. c. of sulphates (the most abundant, sulph. ammonia 8·5 p. c., sulph. magnesia 2·6 p. c.).

Exists also in other natural waters, as at Wiesbaden; Aachen; Krankenheil near Fölz; Clear Lake, in Lake Co., California; and it has been detected in the waters of the ocean.

Occurs also abundantly in the crater of Vulcano, one of the Lipari isles, forming a layer on sulphur, and about the fumaroles, where it was discovered by Dr. Holland in 1813.

Kenngott states that artificial crystals are *monoclinic*; with $I \wedge I=118° 4'$, $I \wedge i\text{-}i=120° 50'$ and twinned parallel to $i\text{-}i$ (Ber. Ak. Wien, xii. 26).

595. SZAIBELYITE. Szaibelyit *K. F. Peters*, Ber. Ak. Wien, xliv. 143, June, 1861

In small nodules bristled with acicular crystals.

H.=3–4. G.=3. Color white outside, yellow within. Streak white Translucent. Optically biaxial.

Comp.—O. ratio for $\dot{Mg}$, $\dddot{B}$, $\dot{H}$=15 : 18 : 4; formula 3 $\dot{Mg}^5 \dddot{B}^2+4 \dot{H}$, Stromeyer; or, if part of this water be basic, $(\frac{5}{6} \dot{Mg}+\frac{1}{6} \dot{H})^3 \dddot{B}+\frac{1}{6} \dot{H}$.

Analyses: 1, 2, Stromeyer (Ber. Ak. Wien, xlvii. 347); 3, Sommaruga (ib., xlviii. 548):

	$\dddot{B}$	$\dot{Mg}$	$\dot{H}$	Cl	$\dddot{\bar{Fe}}$	$\dddot{Si}$
1. *Needles*	36·66	52·49	6·99	0·49	1·66	0·20=98·49 Strom.
2. *Kernels*	34·60	49·44	1_·37	0·20	3·20	——=99·81 Strom.
3. *Needles*	37·38	53·25	6·77	0·51	1·78[a]	0·31=100 Sommaruga.

[a] 2 $Fe^2 O^3$, 3 H O.

Anal. 1 and 3 afford, after separating impurities, the iron as $\dddot{\bar{Fe}}^2 \dot{H}^3$:

$\dddot{B}$		$\dot{Mg}$		$\dot{H}$	
	38·35		54·65		7·00
	38·38		54·67		6·95

Pyr., etc.—Yields water. B.B. splits open, glows, and fuses to a pale, hornlike, brownish-gray mass, coloring the flame yellowish-red.

Obs.—Occurs in kernels imbedded in a gray granular limestone at Werksthal in southeastern Hungary.

Named after Szajbelyi, who collected the limestone containing it.

596. HYDROBORACITE. *G. Hess*, Pogg., xxxi. 49, 1834. Hydrous Borate of Lime and Magnesia.

Resembles fibrous and foliated gypsum.

H.=2. G.=1·9—2. Color white, with spots of red from iron. Thin plates translucent.

Comp.—$\dot{Ca}^3 \dddot{B}^4+\dot{Mg}^3 \dddot{B}^4+18 \dot{H}=(\frac{1}{2} \dot{Ca}+\frac{1}{2} \dot{Mg})^3 \dddot{B}^4+9 \dot{H}$; or, making the water basic, $(\frac{1}{2} \dot{H}+\frac{1}{2} (\dot{Ca}, \dot{Mg}))^3 \dddot{B}$;=Boric acid 47·8, lime 14·3, magnesia 10·2, water 27·7=100. Analyses by Hess (Pogg., xxxi. 49):

	$\dddot{B}$	$\dot{Ca}$	$\dot{Mg}$	$\dot{H}$
1.	49·92	13·30	10·43	26·38=100.
2.	49·22	13·74	10·71	26·33=100.

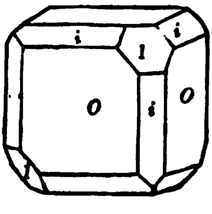
Pyr., etc.—B.B. fuses to a clear glass, tinging the flame slightly green, and not becoming opaque. In a matrass affords water. Somewhat soluble in water, and yielding a slightly alkaline reaction. Dissolves easily in muriatic and nitric acids.

Obs.—Hydroboracite was first observed by Hess, in a collection of Caucasian minerals. The specimen was full of holes filled with clay, containing different salts. It may be mistaken for gypsum, but is readily distinguished by its fusibility.

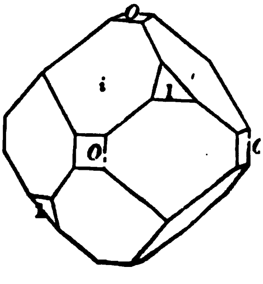
597. BORACITE. Kubische Quarz-Krystalle (fr. Lüneburg) *Lasius*, Crell's Ann., ii. 333, 1787 Lüneburger Sedativ-Spath *Westrumb*, Kl. phys.-ch. Abh., iii. 167, 1789. Borazit *Wern.*, Bergm. J., 1789, 393, 1790, 234. Borate of Magnesia. Magnésie boratée *Fr.* Parasit *O. Volger*, Pogg., xcii. 77, 1854. Massive Boracite of Stassfurt=Stasfurtit *G. Rose*, Pogg., xcvii. 632, 1856.

Isometric; tetrahedral. Figs. 1, 29, 30, and the annexed. Observed planes as in the figures, with also 2-2, 5-$\frac{5}{3}$, on alternate angles only. Cleavage: octahedral, in traces. Cubic faces sometimes striated parallel to alternate pairs of edges, as in pyrite.

490



491



H.=7, in crystals; 4·5, massive. G.=2·974, Haidinger; 2·9134, massive, Karsten. Lustre vitreous, inclining to adamantine. Color white, inclining to gray, yellow, and green Streak white. Subtransparent—translucent. Fracture conchoidal, uneven Pyroelectric, and polar along the four octahedral axes.

Var.—1. *Ordinary*. In crystals. 2. *Massive*, with sometimes a subcolumnar structure; *Stassfurtite* of Rose. It resembles a fine-grained white marble or granular limestone. *Parasite* of Volger is the plumose interior of some crystals of boracite.

Comp.—$\dot{M}g^3\bar{B}^4 + \frac{1}{2}$ Mg Cl=Boric acid 62·6, magnesia 26·8, chlorid of magnesium 10·6=100 Analyses: A. of crystals: 1, Stromeyer (Gilbert's Ann., xlviii. 215); 2, Arfvedson (Ak. H Stockh., 1822, 92); 3, Rammelsberg (Pogg., xlix. 445); 4, Weber (Pogg., lxxx. 282); 5, 6, Potyka (Pogg., cvii. 433); 7, 8, Siewert and Geist (J. pr. Ch., lxxvii. 338).

B. Of Massive Boracite or Stassfurtite: 1, Karsten (Pogg., lxx. 557, 1847); 2, C. F. Chandler (Inaug. Diss.); 3, Siewert & Drenkham (ZS. Nat. Ver. Halle, xi. 365); 4, H. Ludwig (Arch. Pharm., II. xcvi. 129); 5, Heintz (J. pr. Ch., lxxvi. 248); 6, Potyka (Pogg., cvii. 438); 7, Kromayer (Arch. Pharm., II. xcviii. 139):

An *iron-boracite* (Eisenstassfurtit) from Stassfurt is described by Huyssen (Jahrb. Min. 1865, 329), having half the $\dot{M}g$ replaced by $\dot{F}e$.

Westrumb, who was the first to detect in boracite the boric acid (Sedativsalz=Sedative salt of old authors), found (l. c., and also Schrift. Ges. N. Fr. Berlin, ix.) Boric acid 68·0, magnesia 13·5 lime 11·0, alumina 1·0, oxyd of iron 0·75, silica 2·0=96·25. In another trial he obtained $\bar{B}$ 65·0, $\dot{M}g$ 20·5, $\dot{C}a$ 7·0, $\dot{F}e$ 1·25, $\bar{\bar{A}}l$ 2·25, $\ddot{S}i$ 1·0, with 2 of water or loss on ignition=99·0. Several of the subsequent analysts failed to detect the chlorine.

Pyr., etc.—The massive variety gives water in the closed tube. B.B. both varieties fuse at 2 with intumescence to a white crystalline pearl, coloring the flame green; heated after moistening with cobalt solution assumes a deep pink color. Mixed with oxyd of copper and heated on charcoal colors the flame deep azure-blue (chlorid of copper). Soluble in muriatic acid.

Soluble in powder in dilute muriatic, nitric, or sulphuric acids, and the massive kind most readily so. Alters very slowly on exposure, owing to the chlorid of magnesium present, which takes up water.

It is the frequent presence of this deliquescent chlorid in the massive mineral, thus originating, that led to the view that there was a hydrous boracite (stassfurtite). See on this point Bischof's Steinsalzwerke bei Stassfurt, p. 36, and Steinbeck in Pogg., cxxv. 68. *Parasite* of Volger is a result of the same kind of alteration in the interior of crystals of boracite, which gives the somewhat plumose character it has, and the water. Weber's analysis above was probably made on such an altered crystal.

Obs.—Observed in beds of anhydrite, gypsum, or salt. In crystals at Kalkberg and Schildstein in Lüneburg, Hanover; at Segeberg, near Kiel, in Holstein; at Luneville, La Meurthe, France; massive, or as part of the rock of the Salt Mine at Stassfurt, Prussia.

Boracite was first shown to be pyroelectric by Haüy in 1791.

598. RHODIZITE. Rhodizit *G. Rose*, Pogg., xxxiii. 253, 1834, xxxix. 321. Rhodicit *Hausm*

Isometric and tetrahedral, like boracite. Planes 1 smooth and shining, s often uneven.

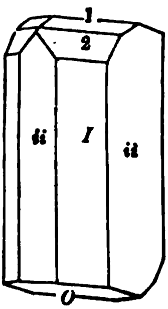
H.=8. G.=3·3—3·42. Lustre vitreous, inclined to adamantine. Color white. Translucent Pyroelectric.

Pyr., etc.—B.B. in the platinum forceps fuses with difficulty on the edges to a white opaque glass, tinging the flame at first green, then green below and red above, and finally red throughout With borax and salt of phosphorus fuses to a transparent glass. Supposed to be lime-boracite.

Obs.—Found by G. Rose in minute crystals on red tourmalines from near Sarapulsk and Schaitansk in the vicinity of Katharinenburg, and named from ῥοδίζειν, in allusion to its tinging flame red. The largest crystals seen were two lines in diameter.

599. BORAX. Tinkal of *India*. Chrysocolla (ex nitro confecta), Borras, *Agric.*, 1546. Borax *Wall.*, Min., 1748. Borate of Soda. Boraxsaures Natron *Germ.* Soude boratée *Fr.*

492



Monoclinic. $C=73°\ 25'$, $I \wedge I=87°$, $O \wedge 2\text{-}\bar{i}=132°\ 49'$; $a : b : c=0{\cdot}4906 : 1 : 0{\cdot}9095$. Observed planes as in the annexed figure, with also $4\text{-}\bar{i}$. $O \wedge I=78°\ 40'$ and $101°\ 20'$, $O \wedge 1=139°\ 30'$, $O \wedge 2=115°\ 53'$, $O \wedge 4\text{-}\bar{i}=114°\ 51\tfrac{1}{2}'$, $O \wedge i\text{-}\bar{i}=90°$, $i\text{-}i \wedge I=133°\ 30'$. Cleavage: $i\text{-}i$ perfect; I less so; $i\text{-}\bar{i}$ in traces. Plane of composition $i\text{-}i$; $O \wedge O=146°\ 50'$.

H.=2—2·5. G.=1·716. Lustre vitreous—resinous; sometimes earthy. Color white; sometimes grayish, bluish or greenish. Streak white. Translucent—opaque. Fracture conchoidal. Rather brittle. Taste sweetish-akaline, feeble.

Comp.—$\dot{\rm N}{\rm a}\,\dddot{\rm B}^2+10\,\dot{\rm H}$; or $(\tfrac{1}{2}\dot{\rm N}{\rm a}+\tfrac{1}{2}\dot{\rm H})\dddot{\rm B}+4\tfrac{1}{2}\dot{\rm H}$=Boric acid 36·6, soda 16·2, water 47·2.

Pyr., etc.—B.B. puffs up, and afterward fuses to a transparent globule, called the glass of borax. Fused with fluor spar and bisulphate of potash it colors the flame around the assay a clear green. Soluble in water, yielding a faintly alkaline solution. Boiling water dissolves double its weight of this salt.

Obs.—Borax was originally brought from a salt lake in Thibet. The borax is dug in masses from the edges and shallow parts of the lake, and in the course of a short time the holes thus made are again filled. This crude borax was formerly sent to Europe under the name of tincal, and there purified. It is announced by Dr. J. A. Veatch as existing in the waters of the sea along the California coast, and in those of many of the mineral springs of California (J. Frankl. Inst., 1860). Crystals, 2 or 3 inches across, occur in the mud of Borax Lake, near Clear Lake, Cal., 65 m. N.W. of Suisun Bay and 36 m. from the Pacific. It has also been found at Viquintizoa and Escapa in Peru; at Halberstadt in Transylvania; in Ceylon. It occurs in solution in the mineral springs of Chambly, St. Ours, etc., Canada East (Hunt, Logan's G. Rep., 1853).

The waters of Borax Lake, California, contain, according to G. E. Moore, 535·08 grains of crystallized borax to the gallon (Am. J. Sci., xli. 257).

Borax is now extensively made from the boric acid of the Tuscan lagoons, by the reaction of this acid on carbonate of soda. This salt is employed in several metallurgical operations as a flux, is sometimes used in the manufacture of glass and gems, and extensively in the process of soldering.

Named borax from the Arabic *buraq*, which included also the *nitre* (carbonate of soda) of ancient writers, the *natron* of the Egyptians.

Prof. Bechi has analyzed a borate occurring as an incrustation at the Tuscan lagoons, which afforded $\dddot{\rm B}$ 43·56, $\dot{\rm N}{\rm a}$ 19·25, $\dot{\rm H}$ 37·19=100, giving the formula $\dot{\rm N}{\rm a}\,\dddot{\rm B}^2+6\,\dot{\rm H}$ (Am. J. Sci., II. xvii. 128).

600. BECHILITE. Hayesine? *Bechi*, Am. J. Sci., II. xvii. 129, 1854. Bechilite *Dana*. Hydrous Borate of Lime.

In crusts, as a deposit from springs.

Comp.—O. ratio for $\dot{\rm C}{\rm a}$, $\dddot{\rm B}$, $\dot{\rm H}$=1 : 6 : 4; $(\tfrac{1}{2}\dot{\rm C}{\rm a}+\tfrac{1}{2}\dot{\rm H})\dddot{\rm B}+1\tfrac{1}{2}\dot{\rm H}$=Boric acid 52·2, lime 20·9 water 26·9=100. Analysis: Bechi (l. c.):

$\dddot{\rm B}$ 51·13 $\dot{\rm C}{\rm a}$ 20·85 $\dot{\rm H}$ 26·25 $\dddot{\rm S}{\rm i}$, $\dddot{\overline{\rm A}}{\rm l}$, $\dot{\rm M}{\rm g}$ 1·75=99·98.

Pyr., etc.—Yields water. B.B. fuses easily, coloring the flame reddish-yellow; moistened with sulphuric acid the flame is colored green.

Obs.—Found by Bechi as an incrustation at the baths of the boric acid lagoons of Tuscany

Artif.—A hot-water solution of ulexite, after concentration and cooling, yielded Lecanu (J Pharm., III. xxiv. 22) scales of a salt having the above ratio, as determined by him. Kraut obtained, under similar circumstances, the compound $\dot{C}a^2\dddot{B}^2+6\dot{H}$, or $5\dot{H}$ after drying over sulphuric acid, and $3\dot{H}$ after heating to 120° C.

The *Hayesine* of D. Forbes (Phil. Mag., IV. xxv. 113), from the waters of the hot springs Baños del Toro, in the Cordilleras of Coquimbo, may be of the above species. It occurs in the waters in the form of snow-white silky or feathery flakes, and also as a flaky sediment at the bottom.

Forbes suggests that the mineral is formed by the action of hot vapors, volcanic in source, on the lime of the waters through which they pass.

601. HOWLITE. Silicoborocalcite *H. How*, Phil. Mag., IV. xxxv. 1868. Howlite *Dana*.

In small rounded imbedded nodules. Texture compact, without cleavage; also chalk-like or earthy.

H.=3·5; often less. G.=2·55. Lustre subvitreous, glimmering. Color white. Subtranslucent, or translucent in thin splinters. Fracture nearly even and smooth.

Comp.—A hydrous borate of lime, similar to *bechilite*, combined with one-sixth of a silicate, analogous to *danburite*. O. ratio for $\dot{R}$, $\dddot{B}$, $\ddot{S}i$, $\dot{H}$=4 : 14 : 4 : 5; corresponding to $[(\frac{1}{2}\dot{C}a+\frac{1}{2}\dot{H})\dddot{B}+\frac{3}{4}\dot{H}]+\frac{1}{6}[(\frac{1}{2}\dot{C}a^3+\frac{1}{2}\dddot{B})^2\ddot{S}i^3]$=Boric acid 43·0, silica 15·8, lime 29·4, water 11·8=100. How deduces the O. ratio 4 : 15 : 4 : 5; but as the boric acid was not directly determined, its preference to the preceding is not certain. How writes the formula $2\dot{C}a\ddot{S}i+2(\dot{C}a\dddot{B}^2+\dot{H})+\dot{H}^3\dddot{B}$. Analyses: 1–3, How; 4, the mean after excluding the lime as gypsum:

	$\ddot{S}i$	$\dddot{B}$	$\dddot{S}$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$
1. *Compact*	15·19	[43·33]	1·08	*tr.*	28·90	11·55
2. "	15·44	[44·10]	0·80	*tr.*	28·04	11·62
3. *Chalky*	14·64	[42·45]	1·36	*tr.*	28·85	12·20
4. Mean, gypsum excl.	15·25	[44·22]	—	—	28·69	11·84

Obs.—Occurs in Nova Scotia, in nodules, of the size mostly of filberts, or ¼ in. to ½ in., and rarely 1 to 2 in. through, imbedded in anhydrite or gypsum, at Brookville, about 3 m. S. of Windsor, and associated with ulexite. The harder kind (anal. 1, 2) occurs in anhydrite, and the softer (anal. 3) in gypsum.

602. ULEXITE. Boronatrocalcit *Ulex*, Ann. Ch. Pharm., lxx. 49, 1849. Natron-Kalk-Borat. Ulexite *Dana*, Min., 695, 1850. Natronborocalcite. Tinkalzit (fr. Africa) *Kletzinsky*, Polyt. Centr., 1384, 1859.

In rounded masses, loose in texture, consisting of fine fibres, which are acicular or capillary crystals.

H.=1. G.=1·65, N. Scotia, How. Lustre silky within. Color white. Tasteless.

Comp.—O. ratio for $\dot{N}a$, $\dot{C}a$, $\dddot{B}$, $\dot{H}$=1 : 2 : 18 : 18, Ramm.,=$(\frac{1}{2}\dot{R}+\frac{1}{2}\dot{H})\dddot{B}+\frac{5}{2}\dot{H}$=Boric acid 45·6, lime 12·3, soda 6·8, water 35·3=100. How deduces for the N. Scotia mineral the ratio 1 : 2 : 15 : 15=Boric acid 44·0, lime 14·1, soda 7·8, water 34·1=100. Analyses: 1, Ulex (l. c.); 2, A. Dick (Phil. Mag., IV. vi. 50); 3, Rammelsberg (Pogg., xcvii. 301); 4, Helbig (Dingler's Pol. J., cxlvii. 319); 5–8, Kraut (Arch. Pharm., II. cxii. 25, Jahresb., 1862, 759, Ann. Ch. Pharm., cxxxix. 252); 9, Lunge (ib., cxxxviii. 51); 10, Kletzinski (Polyt. Centr., 1859, 1384 Ramm. Min. Ch., 988); 11, Phipson (C. R., lii. 407); 12, Salvetat (ib., 536); 13, H. How (Am. J S. II. xxiv. 230); 14, id. (ib., xxxii. 9):

14.	"	[44·10]	14·20	7·21	——	34·49	——	=100 How.

G. of anal. 10=1·912.

In analysis 3, 8·17 chlorid of sodium, 0·41 sulphate of soda, and 0·39 sulphate of lime are excluded.

Pyr., etc.—Yields water. B.B. fuses at 1 with intumescence to a clear blebby glass, coloring the flame deep yellow. Moistened with sulphuric acid the color of the flame is momentarily changed to deep green. Not soluble in cold water, and but little so in hot; the solution alkaline in its reactions.

Obs.—Occurs in the dry plains of Iquique, Southern Peru; in the province of Tarapaca* (where it is called *tiza*), in whitish rounded masses, from a hazelnut to a potato in size, which consist of interwoven fibres of the ulexite, with pickeringite, glauberite, halite, gypsum, and other impurities; on the West Africa coast; in Nova Scotia, at Windsor, Brookville, and Newport (H. How), filling narrow cavities, or constituting distinct nodules or mammillated masses imbedded in white gypsum, and associated at Windsor with glauber salt, the lustre internally silky and the color very white; in Nevada, in the salt marsh of the Columbus Mining District, forming layers 2–5 in. thick alternating with layers of salt, and in balls 3–4 in. through in the salt.

Named after Ulex, who gave the first correct analysis of the mineral.

Alt.—Occurs altered to gypsum.

Hayesine Dana (Hydrous Borate of Lime *A. A. Hayes*, Am. J. Sci., xlvi. 377, xlvii. 215, 1844 Borocalcite; Hydroborocalcite *Hausm.*, Handb., 1429, 1847) from southern Peru, is the above. It comes from the same locality, and has the same appearance; and all analyses of the Peruvian mineral since that by Hayes have found soda to be an essential constituent. Hayes obtained $\dddot{B}$ 46·11, $\dot{C}a$ 18·89, $\dot{H}$ 35·00=100, with the formula $\dot{C}a\,\dddot{B}^2+6\dot{H}$; and he attributed the soda found by Ulex to the mixed glauberite.

603. CRYPTOMORPHITE. *H. How*, Am. J. Sci., II. xxxii. 9, 1861.

In kernels apparently uncrystalline, but under a high magnifying power shown to consist of thin tables or plates, rhombic in outline, and about 80° in angle.

Without lustre. Color white.

Comp.—O. ratio for $\dot{N}a$, $\dot{C}a$, $\dddot{B}$, $\dot{H}$, according to How, from an imperfect analysis, 1 : 3 : 27 : 12 =Boric acid 58·5, lime 15·6, soda 5·8, water 20·1=100, and no satisfactory formula. 1 : 3 : 24 12 would give the more probable composition $(\frac{1}{2}(\dot{N}a, \dot{C}a)+\frac{1}{2}\dot{H})\dddot{B}+\dot{H}$=Boric acid 55·6, lime 16·7 soda 6·2, water 21·5=100. Analysis: How (l. c.):

	$\dddot{B}$	$\dot{C}a$	$\dot{N}a$	$\dot{H}$	$\dot{M}g$	$\dddot{S}$
A.	53·98	14·21	7·25	19·76	0·62	3·98=100.
B.	59·10	15·55	5·61	19·72	——	——

B is the result after removing the magnesia and part of the soda in the state of sulphates as impurities.

Pyr., etc.—Same as under ulexite.

Obs.—Occurs in white lustreless kernels of the size of a pea or bean lying between crystals of glauber salt. The tabular character of the material is supposed to be evidence of distinction from ulexite, which is capillary in its forms. Breadth of tables about ·0048 of an inch, Robb.

---

* The province of Tarapaca is between 19° and 21½° S. lat., and 3000 to 3500 feet above the sea.

Named from κρυπτὸς, *concealed*, and μορφὴ, *form*, in allusion to the invisibility of the structure except under a microscope. Found at Windsor, Nova Scotia.

604. LARDERELLITE. *Bechi*, Am. J. Sci., II. xvii. 130.

Very light, white, and tasteless. Appearing under the microscope to be made up of minute oblique rectangular tables; M ∧ T=110°, Amici.

Comp.—$\text{N H}^4\text{O}\,\dddot{\text{B}}^4+4\,\dot{\text{H}}$; or, more probably, making the water partly basic, $(\frac{1}{4}\,\text{N H}^4\text{O}+\frac{3}{4}\,\dot{\text{H}})\,\dddot{\text{B}}+1\frac{1}{4}\,\dot{\text{H}}$. Analysis by E. Bechi (l. c.):

$\dddot{\text{B}}$ 68·556 NH^4O 12·734 $\dot{\text{H}}$ 18·325

Dissolves in hot water, and is transformed into a new salt, represented by the formula $\text{N H}^4\text{O}\,\dddot{\text{B}}^6+9\,\dot{\text{H}}$, or $(\frac{1}{3}\,\text{N H}^4\text{O}+\frac{2}{3}\,\dot{\text{H}})\,\dddot{\text{B}}^2+2\frac{1}{3}\,\dot{\text{H}}$.

Obs.—Occurs at the Tuscan lagoons.

605. LAGONITE. Borate de Fer *Omalius d'Halloy*, 1833. Lagonite *Huot*, Min., i. 290, 1841. Sideroborine *Huot*, i. 273, 1841. Lagunit *Kenng.*

An earthy mineral of an ochreous yellow color.

Comp.—$\dddot{\text{Fe}}\,\dddot{\text{B}}^3+3\,\dot{\text{H}}$=Boric acid 49·5, sesquioxyd of iron 37·8, water 12·7=100. Analysis by Prof. Bechi (Am. J. Sci., II. xvii. 129):

$\dddot{\text{B}}$ 47·95 $\dddot{\text{Fe}}$ 36·26 $\dot{\text{H}}$ 14·02 $\dot{\text{Mg}}$, $\dot{\text{Ca}}$, and loss 1·77

Occurs as an incrustation at the Tuscan lagoons. First mentioned by Beudant.

606. WARWICKITE. *Shepard*, Am. J. Sci., xxxiv. 313, 1838, xxxvi. 85, 1839. Enceladite *T. S. Hunt*, ib., II. ii. 30, 1846, xi. 352.

Monoclinic? *I* ∧ *I*=93°—94°. Usual in rhombic prisms with obtuse edges truncated, and the acute bevelled, summits generally rounded; surfaces of larger crystals not polished. Cleavage: macrodiagonal perfect, affording surface with vertical striæ and traces of oblique cross cleavage.

H.=3—4. G.=3·19—3·43; 3·351, small crystals, and 3·423, large id., Brush. Lustre of cleavage surface submetallic-pearly to subvitreous; often nearly dull. Color dark hair-brown to dull black, sometimes a copper-red tinge on cleavage surface. Streak bluish-black. Fracture uneven. Brittle.

Comp.—Essentially a borotitanate of magnesia and iron, with 15 to 20 p. c. of boric acid, Smith and Brush (Am. J. Sci., II. xvi. 293). T. S. Hunt found in small lustrous unaltered crystals (Am. J. Sci., II. xi. 352):

$\ddot{\text{Ti}}$ 31·5 $\dot{\text{Mg}}$ 43·5 $\dot{\text{Fe}}$ 8·1 ign. 2·0

with a loss of 14·99 p. c., which Smith and Brush show to be boric acid.

Pyr., etc.—Yields water. B.B. infusible, but becomes lighter in water; moistened with sulphuric acid gives a pale green color to the flame. With salt of phosphorus in O.F. a clear bead, yellow while hot and colorless on cooling; in R.F. on charcoal with tin a violet color (titanic acid). With soda a slight manganese reaction. Decomposed by sulphuric acid; the product, treated with alcohol and ignited, gives a green flame, and boiled with muriatic acid and metallic tin gives on evaporation a violet-colored solution.

Obs.—Occurs in granular limestone 2½ m. S.W. of Edenville, N. Y., with spinel, chondrodite, serpentine, etc. Crystals usually small and slender; sometimes over 2 in. long and ½ in broad. The latter are the *enceladite* of Hunt.

5. TUNGSTATES, MOLYBDATES, VANADATES.

ARRANGEMENT OF THE SPECIES.

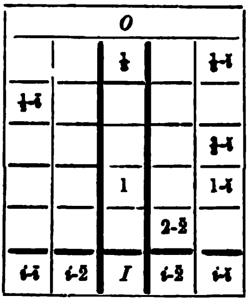
610. WOLFRAMITE. Lupi Spuma, Lapis niger ex quo conflatur candidum plumbum [=Tin], *Agric.*, Foss., 255, 1546. Volfram, Ferrum arsenico mineralisatum, Spuma Lupi (fr. tin veins), *Wall.*, Min., 268, 1747. Magnesia [=Manganese] parva cum portione martis et jovis mixta, Wolfram (fr. Altenberg), *Cronst.*, Min., 107, 1758. Wolfram=TUNGSTIC ACID, Iron, and Mang., *d'Elhuyar*, Chem. Zergl. Wolframs., 1785. Tungstate of Iron and Manganese. Scheelin ferrugineé *H.*, Tr., iv. 1801. Wolframit *Breith.*, Char., 227, 1832.

Orthorhombic. $I \wedge I$=101° 5′, Rose (101° 45′, Kerndt; 101°, Descloizeaux); $I \wedge$ *i-ī*=140° 32′; *i-ī* $\wedge$ *½-ī*=117° 20′; *1-ĭ* $\wedge$ *1-ĭ*, over the summit, =99° 12′; *i-ī* $\wedge$ *i-2̄*=157° 38′. Crystals often monoclinic in habit, half of the planes ½, 1, *½-ī*, and *2-2̆*, being absent or much smaller than the other half. Cleavage: *i-ĭ* perfect, *i-ī* imperfect. Twins: planes of composition *i-ī*, *½-ĭ*, and rarely *½-ĭ*. Also irregular lamellar; coarse divergent columnar; massive granular, the particles strongly coherent.

H.=5—5·5. G.=7·1—7·55. Lustre submetallic. Color dark grayish or brownish-black. Streak dark reddish-brown to black. Opaque. Sometimes weak magnetic.

Var.—The most important varieties depend on the proportions of the iron and manganese Those rich in manganese have G.=7·19—7·54, but generally below 7·25, and the streak is mostly black. Those rich in iron have G.=7·2—7·54, and a dark reddish-brown streak, and they are sometimes feebly attractable by the magnet.



Observed Planes.

Vauquelin gives for the composition of a wolfram from the Department of Haute Vienne, Ẅ 73·60, Ḟe 14·46, Ṁn 11·95=100 (Ann. Ch. Phys., xxx. 261); and Richardson found for one from Bohemia, Ẅ 73·60, Ḟe 11·20, Ṁn 15·75=100·55 (Thom. Min., i. 487). The former analysis corresponds nearly to the ratio 5 : 4 for the two tungstates; and the latter to 3 : 4 nearly.

Hoppe-Seyler (Ann. Ch. Pharm., cxl. 247) found indium in two specimens of wolfram; one contained 0·228 p. c.

The metal tungsten was first recognized in this mineral by the brothers J. Joseph and F d'Elhuyar, in 1785 (Ch. Anal. of Wolfram, etc., translated from the Spanish by Ch. Cullen, London 1785, a work of which a German translation by Gren was published at Halle in 1786). They obtained from the Zinnwald mineral Tungstic acid 65·0, oxyd of manganese 22·0, of iron 13·5=100·5.

Pyr., etc.—B.B. fuses easily (F.=2·5—3) to a globule, which has a crystalline surface and is magnetic. With salt of phosphorus gives a clear reddish-yellow glass while hot, which is paler on cooling; in R.F. becomes dark red; on charcoal with tin, if not too saturated, the bead assumes on cooling a green color, which continued treatment in R.F. changes to reddish-yellow. With soda and nitre on platinum foil fuses to a bluish-green manganate. Decomposed by aqua regia with separation of tungstic acid as a yellow powder, which, when treated B.B., reacts as under tungstite (p. 186). Wolfram is sufficiently decomposed by concentrated sulphuric acid, or even muriatic acid, to give a colorless solution, which, treated with metallic zinc, becomes intensely blue, but soon bleaches on dilution.

Obs.—Wolfram is often associated with tin ores; also in quartz, with native bismuth, tungstate of lime, pyrite, galenite, blende, etc. It occurs at Cornwall, much to the detriment of the tin ores. Found in fine crystals at Schlackenwald, Schneeberg, Geyer, Freiberg, Altenberg, Ehrenfriedersdorf, Zinnwald, and Nertschinsk, and other places mentioned above; at Chanteloup, near Limoges, in France; near Redruth and elsewhere in Cornwall; in Cumberland (the ratio 2 : 3 at Lochfells, that of 4 : 1 at Godolphin's Ball); on the Island of Rona, one of the Hebrides; in the auriferous sand of the Wicklow rivers, Ireland, with tin. Also in S. America, at Oruro in Bolivia. The crystals of Zinnwald are remarkable as hemitropes.

In the U. States it occurs at Lane's mine, Monroe, Conn., in quartz, associated with native bismuth and the other minerals above mentioned, often pseudomorphous after tungstate of lime; in small quantities at Trumbull, Conn., at the topaz vein; massive and in crystals on Camdage farm, near Blue Hill Bay, Me.; at the Flowe mine, Mecklenburg Co., N. C., with scheelite, crystals with planes *I*, *i*-ī, ½-ī, 1-ī; in Missouri, near Mine la Motte, and in St. Francis Co., 1½ m. from St. Francis River; in a gneiss boulder on the W. shore of Chief Island, L. Couchiching, Canada West; at Mammoth mining district, Nevada.

This species is shown to be isomorphous with columbite by G. Rose (Pogg., lxiv. 171). Descloizeaux found in the angles of wolfram some evidence that the crystals were monoclinic. But G. Rose shows from the twins that the form is orthorhombic and not oblique.

Alt.—Wolfram occurs altered to scheelite by a substitution of lime for iron.

611. HÜBNERITE.

E. Riotte, Reese River (Cal.) Reveille, 1865; *H. Credner*, in B. H. Ztg., xxiv. 370, 1865.

Orthorhombic. *I* ∧ *I*=105°. Cleavage: *i*-ĭ very perfect. Commonly in columnar masses or foliated.

H.=4·5. G.=7·14, Breith. Lustre adamantine on face of cleavage, elsewhere greasy. Color brownish-red to brownish-black. Streak yellowish-brown. Opaque. Fracture uneven.

Comp.—$\dot{M}n\,\dddot{W}$=Tungstic acid 76·6, protoxyd of manganese 23·4=100. Analyses: 1, Riott & Hübner (l. c.); 2, C. S. Rodman (priv. contrib.):

	$\dddot{W}$	$\dot{M}n$	$\dot{F}e$
1. Nevada	76·4	23·4	——=99·8 R. & H.
2. "	[75·45]	24·31	0·24=100 Rodman.

Pyr., etc.—B.B. in the forceps less fusible than wolfram; with the fluxes gives manganese and tungstic acid reactions. Partially soluble in muriatic acid, leaving a yellow residue, soluble in ammonia.

Obs.—From the Erie and Enterprise veins, in Mammoth dist., Nevada, in a vein 3—4 feet wide in argillite, with scheelite, fluor, and apatite.

612. FERBERITE. Ferberit *K. L. T. Liebe*, Jahrb. Min. 1863, 641, attributing the name to Breithaupt.

Massive, granular, with some imperfect planes of crystallization. Cleavage: *i-ĭ* very distinct.

H.=4—4½. G.=6·801, Breith.; 7·109, Ramm. Lustre imperfectly vitreous, a little submetallic-adamantine. Color black. Streak brownish-black to blackish-brown. Opaque.

Comp.—Tungstate of iron with a little manganese; O. ratio for $\dot{R}$, $\dddot{W}$=1 : 2·14 to 1 : 2·23, or nearly 1 : 2¼ (instead of 1 : 3, as in wolfram); giving the formula $\dot{R}^4\dddot{W}^3$, with $\dot{F}e$: $\dot{M}n$=8 : 1. Analyses: 1, Liebe (l. c.); 2–4, Rammelsberg (J. pr. Ch., xcii. 263):

1. Spain, *Ferberite*		70·11	0·14	23·29	3·02	0·42	1·75, $\dddot{\bar{A}}l$ 1·17=99·90 Liebe.
2. "	"	69·88		26·68		3·09	=99·60 Ramm.
3. "	"	70·65		25·97	2·17	—	1·52=100 Ramm.
4. "	"	69·88	0·16	25·34	3·00	—	1·62=100 Ramm.

Pyr., etc.—B.B. on charcoal fuses easily to a magnetic globule.

Obs.—Occurs in the Sierra Almagrera in southern Spain, in argillaceous schist, with quartz. Named after R. Ferber of Gera.

613. MEGABASITE. Megabasit *Breith.*, B. H. Ztg., xi. 189, 1852. Blumit *K. L. T. Liebe*, Jahrb. Min. 1863, 652, attributing name to Breithaupt.

Orthorhombic, with the angles of wolfram, Blum. Cleavage: *i-ĭ* distinct; *I* in traces. Occurs in fine needles.

H.=3·5—4. G.=6·45, fr. Schlackenwald, Ramm.; 6·967, ib., Breith.; 6·969, fr. Sadisdorf, id.; 6·939, fr. Morococha, id. Lustre vitreous, a little adamantine. Color brownish-red, clove-brown to yellowish-brown, with a reddish-brown to hyacinth-red translucency. Streak pale yellowish-brown to ochre-yellow.

Comp.—Tungstate of manganese with a little iron; O. ratio for $\dot{R}$, $\dddot{W}$=1 : 2¼, as in ferberite; formula $\dot{R}^4\dddot{W}^3$, with $\dot{F}e$: $\dot{M}n$=1 : 4.

Rammelsberg gives the O. ratio 1 : 3; but his anal. 3, which he says was made on the purest material, sustains 1 : 2¼.

Analyses: 1–3, Rammelsberg (3d Supp., 127, Min. Ch., 309):

	$\dddot{\mathrm{W}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Ca}}$	$\dddot{\mathrm{Si}}$	$\overline{\dddot{\mathrm{Al}}}$	$\dot{\mathrm{P}}$, F	ign.

[a] Trace of silica.

The brothers Elhuyart obtained (see for ref. under WOLFRAM) $\dddot{W}$ 68, $\dot{C}a$ 30, ign. 2=100.

Pyr., etc.—B.B. in the forceps fuses at 5 to a semi-transparent glass. Soluble with borax to a transparent glass, which afterward becomes opaque and crystalline. With salt of phosphorus forms a glass, colorless in outer flame, in inner green when hot, and fine blue cold; varieties containing iron require to be treated on charcoal with tin before the blue color appears. In muriatic or nitric acid decomposed, leaving a yellow powder soluble in ammonia.

Obs.—Tungstate of lime is usually associated with crystalline rocks, and is commonly found in connection with tin ore, topaz, fluorite, apatite, molybdenite, or wolfram, in quartz.

Occurs at Schlackenwald and Zinnwald in Bohemia; in the Riesengebirge; in fine crystals at Caldbeck Fell, near Keswick, with apatite, molybdenite, and wolfram. Also at Schellgaden in Salzberg; Neudorf in the Harz; Ehrenfriedersdorf in Saxony; Pösing in Hungary; Traversella in Piedmont, in fine crystals, sometimes transparent; Dalecarlia and Bitsberg in Sweden; Framont in the Vosges, with pyrite in polished crystals, giving Delesse for the angles of octahedron 1, 100° 5′ and 130° 31′, G.=6·05; at the copper mines of Llamuco, near Chuapa in Chili, of a reddish-gray color, mixed with green, due to chrysocolla.

In the United States, crystallized and massive at Lane's Mine, Monroe, and at Huntington, Conn., with wolfram, pyrite, rutile, and native bismuth, in quartz; at Chesterfield, Mass., in albite, with tourmaline; in the Mammoth mining district, Nevada; at Bangle mine, in Cabanas Co., N. C.; and Flowe mine, Mecklenburg Co., some crystals at the latter locality having a nucleus of wolfram.

Tungstic acid was discovered in this species by the Swedish chemist Scheele, in 1781. The word *tungsten*, first used by Cronstedt, is Swedish for *heavy stone*.

Alt.—Occurs altered to wolfram, a tungstate of iron and manganese, by the action of a solution of bicarbonate of iron and manganese, or perhaps mainly through sulphate of iron arising from the decomposition of pyrite. Also to kaolinite (at Ehrenfriedersdorf).

615. CUPROSCHEELITE. *J. D. Whitney*, Proc. Cal. Acad., iii. 287, 1866.

Crystalline-granular. Cleavage distinct in one direction.

H.=4·5–5. Lustre highly vitreous. Color pistachio-green, passing to olive- and leek-green. Streak light greenish-gray.

Comp.—O. ratio for $\dot{R}$, $\dddot{W}$=1 : 3; $\dot{C}u\ \dddot{W}+2\ \dot{C}a\ \dddot{W}$=Tungstic acid 78·43, oxyd of copper 8·95, lime 12·62=100. **Analysis:** Whitney (l. c.):

$\dddot{W}$ 79·69 $\dot{C}u$ 6·77 $\dot{F}e$ 0·31 $\dot{C}a$ 10·95 $\dot{H}$ 1·40=99·12.

Pyr., etc.—In the closed tube blackens, and gives off water. B.B. fuses on the edges to a black glass, and colors the flame an intense green. On charcoal blackens, fuses with a little intumescence, forming finally a slag containing minute particles of metallic copper. With fluxes gives tungstic acid and copper reactions. Easily soluble in muriatic acid, tungstic acid being separated.

Obs.—Occurs in the vicinity of La Paz, Lower California, in a red metamorphic rock, associated with black tourmaline.

Domeyko has analyzed a mineral from Chili containing 3·3 p. c. of oxyd of copper. See under SCHEELITE, anal. 11.

616. STOLZITE. Scheel-Bleispath *Breith.*, Char., 14, 1820. Tungstate of Lead. Bleischeelat Wolframbleierz, Scheelsaures Blei, *Germ.* Scheelitine *Beud.*, Tr., ii. 662, 1832. Stolzit *Haid.*, Handb., 504, 1845.

Tetragonal. $O \wedge 1\text{-}i=122°\ 33'$; $a=1{\cdot}567$. Usual forms octahedral. Observed planes: I, 1, $\frac{1}{2}$, 2, $1\text{-}i$; sometimes hemihedral.

$O \wedge \frac{1}{2}=132°\ 4'$	$1 \wedge 1$, pyr.,$=99°\ 44'$	$1\text{-}i \wedge 1\text{-}i$, pyr.,$=106°\ 50'$
$O \wedge 1=114\ 17$	$1 \wedge 1$, bas.,$=131\ 25$	$1\text{-}i \wedge 1\text{-}i$, bas.,$=114\ 54$
$O \wedge 2=102\ 42$	$2 \wedge 2$, pyr.,$=93\ 46$	$2 \wedge 2$, bas.,$=154\ 36$

Crystals often indistinctly aggregated. Cleavage: O imperfect; 1 still more so.

H.=2·75–3. G.=7·87–8·13 Lustre resinous, subadamantine. Color green, yellowish-gray, brown, and red. Streak uncolored. Faintly translucent.

Comp.—$\dot{\mathrm{P}}\mathrm{b}\,\dddot{\mathrm{W}}$=Tungstic acid 51, oxyd of lead 49=100. Analyses: 1, Lampadius (Schw. J., xxxi. 254); 2, Kerndt (J. pr. Ch., xlii. 116):

	$\dddot{\mathrm{W}}$	$\dot{\mathrm{P}}\mathrm{b}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{F}}\mathrm{e}$, $\dot{\mathrm{M}}\mathrm{n}$	
1. Zinnwald	51·75	48·25	——	——	=100 Lampadius.
2. "	(⅓) 51·736	45·993	1·397	0·471	Kerndt.

Pyr., etc.—B.B. decrepitates and fuses at 2 ·; a crystalline, lustrous, metallic pearl. With soda on charcoal yields metallic lead. With salt of phosphorus gives in O.F. a colorless glass, which in R.F. becomes blue on cooling. Decomposed by nitric acid, leaving a yellow residue of tungstic acid.

Obs.—Stolzite occurs at Zinnwald in Bohemia, with quartz and mica; at Bleiberg in Carinthia, with molybdate of lead; in Chili, province of Coquimbo; at Southampton, Mass.

This species was first made known, according to Breithaupt, by Dr. Stolz, of Teplitz.

617. **WULFENITE.** Plumbum spatosum flavo-rubrum, ex Annaberg Austr. *v. Born*, Lithoph., i. 90, 1772. Kärntherischer Bleispath *v. Jacquin*, Miscell. Austr., ii. 1781, Vienna; *Wulfen*, Abhandl. K. 497

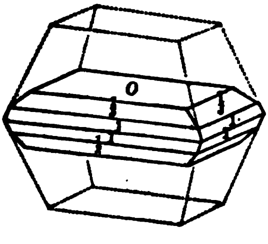
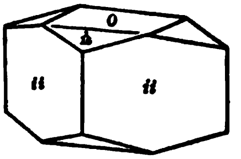
498



Phenixville.

499

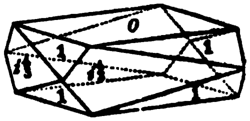


Phenixville.

Cleavage: 1 very smooth; O and $\frac{1}{2}$ much less distinct. Also granularly massive, coarse or fine, firmly cohesive. Often hemihedral in the octagonal prisms, producing thus tables like f. 500, and octahedral forms having the prismatic planes similarly oblique.

H.=2·75–3. G.=6·03–7·01. Lustre resinous or adamantine. Color wax-yellow, passing into orange-yellow; also siskin- and olive-green, yellowish-gray, grayish-white, brown; also orange to bright red.

500



Przibram.

Streak white. Subtransparent—subtranslucent. Fracture subconchoidal. Brittle.

Var.—1. *Ordinary.* Color yellow. 2. *Vanadiferous.* Color orange to bright red, a variety occurring at Phenixville, Pa.

Dauber found for the angle 1 ∧ 1, in crystals from Bleiberg, 131° 42′; fr. Berggieshübel, 131° 47′; fr. Phenixville, 131° 50′; fr. Zinnwald, 131° 57′; and v. Zepharovich, for crystals fr. Przibram, 131° 43′ 38″. The last corresponds to 114° 8′ for *O* ∧ 1. Descloizeaux found for *O* ∧ 1 on Antioquia crystals=114° 20′, and 1 ∧ 1=131° 40′.

Comp.— $\dot{\mathrm{P}}\mathrm{b}\,\dddot{\mathrm{M}}\mathrm{o}$=Molybdic acid 38·5, oxyd of lead 61·5=100. Analyses: 1, Göbel (Schw. J. xxxvii. 71); 2, Melling (Rammelsberg 1st Suppl., 59); 3, 4, Parry and J. Brown (Proc. Phil. Soc Glasgow, April, 1847); 5, C. Bergemann (Pogg., lxxx. 400); 6, 7, J. L. Smith (Am. J. Sci., II xx 245):

	$\dddot{\mathrm{M}}\mathrm{o}$	$\dot{\mathrm{P}}\mathrm{b}$
1. Carinthia	40·5	59·0=99·5 Göbel.
2. "	40·29	61·90=102·19 Melling.
3. "	39·30	60·35=99·65 Parry.
4. "	39·19	60·23=99·42 Brown.
5. Zacatecas	37·65	62·35=100 Bergemann.
6. Phenixville, *yellow*	38·68	60·48=99·16 Smith. G.=6·95.
7. " *red*	37·47	60·30, $\dddot{\mathrm{V}}$ 1·28=99·05 Smith.

A molybdate of lead from Pamplona, S. A., afforded Boussingault (Ann. Ch. Phys., xlv. 325) $\dot{\mathrm{P}}\mathrm{b}$ 78·8, $\dddot{\mathrm{M}}\mathrm{o}$ 10·0, $\ddot{\mathrm{C}}$ 2·9, H Cl 1·3, $\dddot{\bar{\mathrm{P}}}$ 1·3, $\dddot{\mathrm{C}}\mathrm{r}$ 1·2, $\bar{\mathrm{F}}\mathrm{e}$ 1·7, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 2·2, quartz 3·7=98·1. He considers it a basic salt, with the formula $\dot{\mathrm{P}}\mathrm{b}^3\dddot{\mathrm{M}}\mathrm{o}$. Klaproth, who made the first complete analysis, obtained $\dddot{\mathrm{M}}\mathrm{o}$ 34·25, $\dot{\mathrm{P}}\mathrm{b}$ 64·02 (Beitr., ii. 275). A crystallized wulfenite from Chili gave Domeyko (Ann. d. M., IV. iii. 15) $\dddot{\mathrm{M}}\mathrm{o}$ 46·12, $\dot{\mathrm{P}}\mathrm{b}$ 47·00, $\dot{\mathrm{C}}\mathrm{a}$ 0·88; corresponding to $2\,\dot{\mathrm{P}}\mathrm{b}\,\dddot{\mathrm{M}}\mathrm{o}+\dot{\mathrm{C}}\mathrm{a}\,\dddot{\mathrm{M}}\mathrm{o}$. The red color of the Phenixville mineral was shown to be due to vanadic acid by Smith. The massive wulfenite of Garmisch is a mixture of the mineral with quartz, carbonate of lead, etc. (Wittstein in Vierteljahrsschr. pr. Pharm., vii. 70).

Pyr., etc.—B.B. decrepitates and fuses below 2; with borax in O.F. gives a colorless glass, in R.F. it becomes opaque black or dirty green with black flocks. With salt of phosphorus in O.F. gives a yellowish-green glass, which in R.F. becomes dark green. With soda on charcoal yields metallic lead. Decomposed on evaporation with muriatic acid, with the formation of chlorid of lead and molybdic acid; on moistening the residue with water and adding metallic zinc, it gives an intense blue color, which does not fade on dilution of the liquid.

Obs.—This species occurs in veins with other ores of lead. Found first at Bleiberg, Schwarzenbach, and Windisch-Kappel, in Carinthia; also at Raskitza in Austria; at Retzbanya and Szaska in Hungary; at Przibram; at Moldawa in the Bannat, where its crystals are red, and have considerable resemblance to chromate of lead; in the Kirghis Steppes in Russia; at Annaberg, Schneeberg, and Johanngeorgenstadt in Saxony; at Badenweiler in Baden; sparingly at Chalanches, Dept. of Isère, in France; in the gold sands of Rio Chico in Antioquia, Columbia. S. A.; in Lackentyre, Kirkcudbrightshire, Scotland.

It is found in small quantities at the Southampton lead mine, Mass.; in fine yellow and reddish orange to red crystals (fig. 499, and also in thin tables) at Wheatley's mine, near Phenixville, Pa.: at the Comstock lode in Nevada; at Empire mine, Inyo Co., Cal.; in the Weaver dist., Arizona.

For recent papers on cryst. see Dauber, Pogg., cvii. 267; Descl., Ann. Ch. Phys., III. li. 448; v. Zepharovich, Ber. Ak. Wien, liv. 278, 1866; J. L. Smith, Am. J. Sci., II. xx. 245.

618. PATERAITE. Paterait *Haid.*, C. v. Hauer, Jahrb. G. Reichs., vii. 196, 1856, xiv. 303.

Amorphous. Color black.

Composition $\dot{\mathrm{C}}\mathrm{o}\,\dddot{\mathrm{M}}\mathrm{o}$. Analysis by Laube (l. c., xiv. 303):

$\dddot{\bar{\mathrm{M}}}\mathrm{o}$ 30·0 $\dddot{\bar{\mathrm{B}}}\mathrm{i}$ 2·0 $\bar{\mathrm{F}}\mathrm{e}$ 16·6 $\dot{\mathrm{C}}\mathrm{o}$ 27·0 $\dot{\mathrm{H}}$ 8·6 S 12·0, insol. 3·8=100.

The first examination of this mineral was by Patera, and was only qualitative. He found molybdic acid, silica, bismuth, iron, cobalt, and sulphur. Jokely states (Jahrb. G. Reichs., viii. 35) that it consists principally of vanadic and molybdic acids and cobalt. Laube's analysis confirms Patera's result. The mineral is so intimately mixed with pyrite and bismuthinite that, even with the greatest care, it could not be completely separated. Subtracting the bismuth, iron, and sulphur in the above analysis, molybdate of cobalt remains, which, according to Laube, is the true mineral.

B.B. in the closed tube gives water, a sublimate of molybdic acid, and vapors of sulphurous acid. On charcoal melts easily to a black bead, giving a white coating. With borax, bead green when hot (iron), blue when cold (cobalt). Easily soluble in acids.

Discovered by Vogl, in the Elias mine, Joachimsthal, with uranium ores.

Named from A. Patera, who first examined it.

619. DECHENITE. *C. Bergemann*, Pogg., lxxx. 393, 1850. Aræoxen *v. Kob.*, J. pr. Ch., l. 496, 1850. Eusynchit *Fischer & Nessler*, Ber. Ges. Freiburg, 1854, Jahrb. Min. 1855, 570. ? Rhombischer Vanadit *Zippe*, Ber. Ak. Wien, xliv. 1861 (see under DESCLOIZITE).

Massive, botryoidal, nodular, stalactitic; sometimes traces of a columnar structure.

H.=3–4. G.=5·6–5·81. Lustre of fresh fracture greasy. Color fine deep red to yellowish-red and brownish-red; also leather-yellow. Streak orange-yellow to ochre- and pale yellow.

Var.—The original *dechenite* was from Dahn, near Nieder Schlettenbach, in the Lauter Valley, Rhenish Bavaria, and was dull red to yellowish-red in color, botryoidal in surface, with G.=5·81. *Aræoxene* is from the same locality, and is like dechenite in all its characters, except, according to Bergemanu, a duller reddish-brown color, which, however, is not distinctive.

The *Eusynchite* is from Freiburg in Brisgau, yellowish-red to leather-yellow in color, with G.=5·596, Ramm., and H.=3·5; it occurs in nodular and stalactitic forms.

Comp.—$\dot{\text{P}}\text{b}\,\dddot{\text{V}}$, or vanadate of lead, according to the older analyses; but probably in all cases vanadate of lead and zinc, with the formula $(\dot{\text{P}}\text{b}, \dot{\text{Z}}\text{n})\,\dddot{\text{V}}$.

Analyses: 1–3, C. Bergemann (l. c.); 4, id. (Jahrb. Min. 1857, 397); 5, v. Kobell (l. c.); 6, Fischer & Nessler (l. c.); 7, 8, C. Czudnowicz (Pogg., cxx. 17); 9, Ramm. (J. pr. Ch., xci. 418):

9. " "	[24·22]	57·66	15·80, $\dot{\text{C}}\text{u}$ 0·68, $\dddot{\bar{\text{P}}}$ 1·14, $\dddot{\bar{\text{A}}}\text{s}$ 0·50=100 Ramm.

The fact that both dechenite and eusynchite contain a considerable amount of oxyd of zinc was shown by G. J. Brush in 1857 (Am. J. Sci., II. xxiv. 116), and the identity of eusynchite and aræoxene with dechenite suggested. Fischer & Nessler's method of determining the vanadic acid was incorrect (Czudnowicz).

Pyr., etc.—B.B. fuses easily without decrepitation to a yellow glass. On charcoal in R.F. gives lead globules and a white coating, which, treated with cobalt solution, becomes green (zinc). With salt of phosphorus and borax gives an emerald-green bead in R.F., becoming yellowish-green to yellow in O.F. Decomposed by hot muriatic acid, yielding an emerald-green solution. This treated with alcohol, boiled and decanted from the separated chlorid of lead, yields, after evaporation, a solution which, diluted with water, has an azure-blue color (v. Kobell).

Obs.—Occurs with other ores of lead.

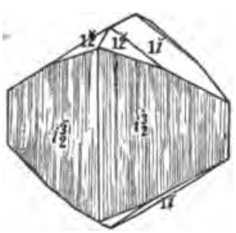
Discovered at Dahn by Dr. Krantz.

Named after the German geologist, von Dechen.

620. DESCLOIZITE. *A. Damour*, Ann. Ch. Phys., III. xli. 72, 78, 1854. Rhombischer Vanadit *Zippe*, Ber. Ak. Wien, xliv. i. 197, 1861, *Tschermak*, ib., ii. 157.

Orthorhombic. $I \wedge I = 100°\ 28'$; $O \wedge 1\text{-}\bar{\imath} = 143°\ 14'$; $a : b : c = 0·747 : 1 : 1·2052$. Angles, Descloizeaux:

501



$i\text{-}\breve{\tfrac{3}{2}} \wedge i\text{-}\breve{\tfrac{3}{2}}$=122° 6′ 1-$\bar{2}$ ∧ 1-$\bar{2}$, ov. base,=91°42
1-ĭ ∧ 1-ĭ, top,=116 25 1-$\bar{2}$ ∧ 1-ĭ=147 35
1-$\bar{2}$ ∧ 1-$\bar{2}$, adj.,=127 10 O ∧ 1-ĭ=148 12$\frac{1}{2}$
1-$\bar{2}$ ∧ 1-$\bar{2}$, ov. 1-ĭ,=115 10

Cleavage none. Plane 1-$\bar{2}$ brightest, 1-ĭ undulated, $i\text{-}\breve{\tfrac{3}{2}}$ vertically striated.

H.=3·5. G.=5·839. Lustre bright. Color black to olive-brown; smallest crystals olive-green, with a chatoyant bronze lustre; by transmitted light along the edges light brown inclining to red; on a surface of fracture, colors zoned with straw-yellow, reddish-brown, and black; nearly clear at middle and darkest at extremities of crystals.

Comp.—$\dot{\mathrm{P}}\mathrm{b}^2\dddot{\mathrm{V}}$=Vanadic acid 29·3, oxyd of lead 70·7=100. Analyses: Damour (l. c.):

	$\dddot{\mathrm{V}}$	$\dot{\mathrm{P}}\mathrm{b}$	$\dot{\mathrm{Z}}\mathrm{n}$	$\dot{\mathrm{C}}\mathrm{u}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{H}}$	Cl	$\dot{\ddot{\mathrm{M}}}\mathrm{n}$	Sand
($\frac{2}{3}$)	22·46	54·70	2·04	0·90	1·50	5·32	2·20	0·32	6·00	8·44=98·88.

The oxyds of manganese, iron, copper, and zinc are regarded as impurities.

Pyr., etc.—In the closed tube gives water. B.B. on charcoal fuses, and is partially reduced to a globule of metallic lead enveloped in a black scoria. With borax in R.F. a green glass, and with nitre in O.F. a violet color due to manganese. With salt of phosphorus in R.F. a glass of a chrome-green color, which is orange-yellow in the O.F. Dissolves in cold dilute nitric acid.

Obs.—Occurs in small crystals, 1 to 2 mm. thick, clustered on a siliceous and ferruginous gangue from South America, and associated with acicular green pyromorphite.

Zippe's *vanadite* (l. c.) is referred to descloizite by A. Schrauf (Pogg., cxvi. 355, 1862). The mineral occurs at Kappel in Carinthia, in small clove-brown rhombic octahedrons, with G.=5·83. Tschermak obtained in his analysis (Ber. Ak. Wien, xliv. ii. 158) $\dddot{\mathrm{V}}$ 45·7, $\dot{\mathrm{P}}\mathrm{b}$ 54·3=100 (with no zinc, although looked for), and referred the species to dechenite. Grailich & Weiss (Pogg., l. c.) make the form orthorhombic, and the angles 1-$\bar{2}$ ∧ 1-$\bar{2}$=125° 28′—125° 56′, 113° 15′—113° 35, and 90° 8′—91° 30′. But A. Schrauf finds for the same angles 126°—128°, 114$\frac{1}{2}$°—115$\frac{1}{2}$°, 91°—92°, agreeing closely with the above of descloizite. Schrauf suggests that both descloizite and vanadite are dechenite; and Tschermak (Pogg, cxvii. 349) that vanadite and dechenite are one species, and descloizite an altered vanadite.

Named after the French mineralogist Descloizeaux.

620A. *Vanadate of Lead*, from Phenixville, Pa. A thin crystalline crust of a dark purple, almost black color, but dark hyacinth-red by transmitted light, and of a dark yellow streak, occurs covering quartz, ferruginous clay, and wulfenite, at Phenixville. With a magnifying glass it appears to consist of minute lenticular crystals. It could not be wholly separated from the associated wulfenite and other impurities for analysis, and the result obtained is therefore not wholly satisfactory. J. L. Smith found (Am. J. Sci., II. xx. 247, 1855): $\dddot{\mathrm{V}}$ 11·70, $\dddot{\mathrm{M}}\mathrm{o}$ 20·14, $\dot{\mathrm{P}}\mathrm{b}$ 55·01, $\ddot{\mathrm{M}}\mathrm{n}$, $\ddot{\mathrm{A}}\mathrm{l}$ 5·90, $\dot{\mathrm{C}}\mathrm{u}$ 1·13, sand 2·21, aq 2·94=99·03. Subtracting the lead required by the molybdic acid to make wulfenite, it leaves 22·82 p. c. for the 11·70 of vanadic acid: which is nearer the composition of descloizite than that of dechenite.

621. VANADINITE. Plomb brun, Braunbleierz of Zimapan, *early authors*. Chromate de Plomb brun (from Descotil's anal.) *Brongn.*, Min., ii. 204, 1807. Vanadinbleierz *G. Rose*, Pogg., xxix. 455, 1833. Vanadinit *v. Kob.*, Grundz., 283, 1838. Vanadate of Lead. Vanadinspath, Vanadinbleispath, Vanadinsaures Blei, *Germ.* Plomo pardo *Domeyko*.

Hexagonal. In simple hexagonal prisms, and prisms terminating in planes of the pyramids 1, $\frac{1}{2}$, 1-2, and 2-2; 1 ∧ 1, over terminal edge, 142° 58′, O ∧ 1=140° 34′, I ∧ 1=130°. Usually in implanted globules or incrustations.

H.=2·75—3. G.=6·6623—7·23; 6·886, Carinthia, Ramm.; 6·863, Beresof, Struve. Lustre of surface of fracture resinous. Color light brownish-yellow, straw-yellow, reddish-brown. Streak white or yellowish. Subtranslucent—opaque. Fracture uneven, or flat conchoidal. Brittle.

Comp.—$\dot{\text{P}}\text{b}^3\dddot{\text{V}}+\frac{1}{3}\text{Pb Cl}$=Vanadate of lead 90·3, chlorid of lead 9·7=100. Analyses · 1, Berzelius (Schw. J., lxiii. 119); 2, R. D. Thomson (Thoms. Min., i. 574); 3, Damour (Ann. d. M., III. xi. 161); 4, Rammelsberg (Min. Ch., 316); 5, 6, Struve (Verh. Min. Ges. St. Petersb., 1857):

6. "	14·54	71·14	7·18	2·46	2·79=98·11 Struve.

Pyr., etc.—In the closed tube decrepitates and yields a faint white sublimate. B.B. fuses easily, and on charcoal to a black lustrous mass, which in R.F. yields metallic lead and a coating of chlorid of lead; after completely oxydizing the lead in O.F. the black residue gives with salt of phosphorus an emerald-green bead in R.F., which becomes light yellow in O.F. Gives the chlorine reaction with the copper test. Fused with 3 parts of bisulphate of potash forms a clear yellow mass, which on cooling reddens, becoming finally of a pomegranate-yellow color. Decomposed by muriatic acid.

If nitric acid be dropped on the crystals they become first deep red from the separation of vanadic acid, and then yellow upon its solution.

Obs.—This mineral was first discovered at Zimapan in Mexico, by Del Rio. It has since been obtained among some of the old workings at Wanlockhead in Dumfriesshire, where it occurs in small globular masses, sprinkled over calamine, or forming thin coatings on the surface of that mineral, and also in hexagonal crystals, the largest not more than ¼ in. across; also at Berosof in the Ural, with pyromorphite; and near Windisch Kappel in Carinthia, in crystals, the angles as above given. This mineral has never been found at Wicklow, Ireland, although so reported by Thomson (Greg and Lettsom).

Schabus gives for the forms from Windisch Kappel *I*, 1; *I*, 1, ½; *I*, 1, 2-2; *O*, *I*, 1, ½; *O*, *I*, 1, 1-2. The basal angle of pyramid 1 in different crystals was 78° 46′—78° 54′. The angles are very near those of mimetite and pyromorphite, the basal angle in the former being 79° 24′—80° 48′; and in pyromorphite of Bleistadt, 80° 40′ (Pogg., c. 297).

Kokscharof regards the crystals from Beresof as pseudomorphs after pyromorphite; and Struve observes that the crystals contain at centre a portion of unaltered pyromorphite (Min. Russl., iii. 44). Del Rio discovered this species at Zimapan, and obtained from it, in 1801, 80·72 of oxyd of lead, and 14·8 of a new metallic acid, the basis of which he called *Erythronium*. This result was set aside by himself in the Ann. des Sci. Nat. de Madrid, Feb. 1804 (Ann d. M., iv. 1819), and also by Descotils in the Ann. Ch., liii. 1805, both of whom made the acid the chromic, and the mineral a *brown* chromate of lead. The metal vanadium was not discovered by Sefstrom until 1830, and then in iron made of ore from Taberg, Sweden; and in the same year Wöhler showed that Del Rio's lead ore was a vanadate.

622. VOLBORTHITE. *Hess*, Bull. Ac. St. Pet., iv. 1838, and J. pr. Ch., xiv. 52. Knauffite. Vanadate of Copper. Vanadinsaures Kupfer.

Hexagonal. In small six-sided tables, often aggregated in globular forms. Cleavage: in one direction very perfect.

H.=3—3·5. G.=3·55, Credner. Lustre pearly to vitreous. Color olive-green, citron-yellow. Streak clear yellowish-green, nearly yellow. Thin splinters translucent

Comp.—According to Hess (l. c.) a hydrous vanadate of copper.

Pyr., etc.—B.B. on charcoal fuses easily to a black bead, which in the inner flame becomes blackish-gray. With soda or charcoal yields copper; with borax and salt of phosphorus reactions for copper. Fused with soda in the platinum spoon, the mass yields on treatment with water a solution which, acidulated with muriatic acid and boiled, gives an emerald-green solution, and this diluted with water becomes blue; v. Kobell.

Obs.—From Syssersk and Nischne Tagilsk in the Urals, where it was found by Dr. A. Volborth, and from several mines of the Permian formation in the government of Perm, especially at the Alexandroff mine in the Motowilich District.

622A. **Vanadate of Lime and Copper** (Kalk-Volborthit). Near volborthite, but containing lime, and found at Friederichsrode in Thuringia. There are two varieties, according to Credner (Pogg., lxxiv. 546, 1848); (1) a green, in thin tables, cleaving easily in one direction, greenish-yellow in streak, pearly in lustre, with G.=3·495; (2) a gray, fine crystalline granular, brownish-yellow in streak, with H.=3·5, and G.=3·860.

Analyses by Credner (l. c.):

		$\dddot{\bar{V}}$	$\dot{C}u$	$\dot{C}a$	$\dot{M}g$	$\dot{M}n$	$\dot{H}$		
1.	*Green*	(?) 36·58	44·15	12·28	0·50	0·40	4·62,	gangue	0·10=98·63
2.	*Light-green*	[36·91]	38·90	17·40	0·87	0·58	4·62,	"	0·77=100.
3.	*Gray*	39·02	38·27	16·65	0·92	0·52	5·05,	"	0·76=101·19

The results correspond most nearly with the formula $(\dot{C}u, \dot{C}a)^4 \dddot{\bar{V}} + aq$. The ratio of $\dot{C}u$ to $\dot{C}a$ in No. 1 is about 5 : 2; and in 2 and 3, 3 : 2.

623. **Chileite** *Kenng.*, Mohs'sche Min., 28, 1853 (Vanadate of Lead & Copper *Domeyko*, Ann. d. M., IV. xix. 150, 1848; Vanadinkupferbleierz). This ore has a dark brown or brownish-black color, and has been observed only in an earthy state, looking much like a ferruginous clay or earth. It occurs in cavities in an arseno-phosphate of lead along with amorphous carbonates of lead and copper. B.B. fuses easily, and affords a black pearl, a little blebby; gives a clear green pearl with salt of phosphorus or borax, and a globule of lead containing copper on charcoal. In nitric acid easily soluble.

Comp.—$\dot{P}b^6 \dddot{\bar{V}} + \dot{C}u^6 \dddot{\bar{V}}$. Analyses by Domeyko (l. c.):

	$\dddot{\bar{V}}$	$\dddot{\bar{A}}s$	$\dddot{\bar{P}}$	$\dot{C}u$	$\dot{P}b$	Pb Cl	$\dot{C}a$	$\dddot{\bar{F}}e, \dddot{\bar{A}}l$	$\dddot{S}i$	$\dot{H}$		
1.	13·5	4·6	0·6	14·6	54·9	0·8	0·5	3·5	1·0	2·70,	clay	1·0=97·2.
2.	13·33	4·68	0·68	16·97	51·97	0·37	0·58	3·42	1·33	2·70,	"	1·52=97·55.

Considering the arsenic and phosphoric acids as combined with lead, constituting the arsenic phosphate with which the mineral is associated, the analysis affords very closely the above formula.

This ore occurs at the silver mine called Mina Grande, or Mina de la Marqueza, in Chili, til recently worked for copper and silver.

623A. *Vanadate from the Lake Superior Copper Region.* An ore similar in color and clayey appearance to Domeyko's mineral, has been announced by J. E. Teschemacher among specimens from the Cliff Mine, in the Lake Superior Copper Region. The presence of vanadium was ascertained by both blowpipe and acid tests. The color is a dark chocolate, and also a bright yellow. The exact state of composition of the vanadic acid is doubtful. There is no oxyd of lead in the ore, and the brown variety is mixed with an earthy oxyd of iron; when carefully separated from the gangue it was found to contain no copper. This Min., 531, 1850.

---

6. SULPHATES, CHROMATES, TELLURATES.

In crystalline form, specific gravity, and color, the Sulphates vary almost indefinitely. The hardness is not above 4. The Chromates have bright, deep red, and green to brown colors, with the hardness 2·5—3·5. No native hydrous chromates are known.

The compounds of sulphates and carbonates, or sulphato-carbonates, have the crystallization of the sulphates, the carbonic acid being wholly subordinated, as regards the form produced, to the sulphuric, the more powerful acid. Thus *leadhillite* is homœomorphous with anglesite, celestine, etc., *susannite* with dreelite, and *lanarkite* with glauberite; and these species are accordingly here included.

General Pyrognostic Characters of the Sulphates. The sulphates of the alkalies, the alkaline earths, and oxyd of lead, are not decomposed by heating in the matrass or closed tube; other sulphates, such as those of protoxyd of iron, manganese, etc., are partially decomposed with the evolution of sulphurous and sulphuric acids. On charcoal the sulphates of the alkalies and alkaline earths are in R.F. reduced to sulphids, which, moistened with dilute muriatic acid, evolve sulphuretted hydrogen; the other sulphates thus treated give off sulphurous acid, and leave earths or metallic oxyds, or metals or metallic sulphids, and sometimes, where the metal is volatile, coat the coal with oxyd. All non-volatile sulphates when fused with soda or neutral oxalate of potash on charcoal yield a hepatic mass, which is more or less absorbed by the coal; when this is removed, and placed on a bright clean surface of silver with a drop or two of water, it stains the metal yellowish-brown to black from the formation of sulphid of silver; treated with muriatic acid the fused mass evolves sulphuretted hydrogen. In soluble minerals the sulphuric acid may be readily detected on adding to the solution a few drops of soluble baryta salt, which produces a white precipitate, insoluble in acids and in ammonia.

[a] $SO^3\,HO$.

The water for Hunt's analysis was taken in October, 1847; another portion taken in April, 1846, afforded Croft 2·9069 of sulphuric acid, with the bases in quite different proportions.

The specific gravity of the Alabama water is 1·00482 at 15° C., Erni; of that of Tuscarora 1·00558.

Sulphuric acid results from the oxydation of sulphuretted hydrogen.

Paramo de Ruiz in New Granada, and Rio Vinagre, are volcanic localities.

626. TAYLORITE. Sulphate of Potash and Ammonia *W. J. Taylor*, Proc. Ac. N. Sci. Philad. 309, 1859.

In small compact lumps or concretions; structure crystalline.

H.=2. Color yellowish-white. Taste pungent and bitter. Unalterable in the air.

Comp.—$(\frac{5}{6}KO+\frac{1}{6}NH^4O)\,SO^3$=Sulphuric acid 47·8, potash 47·0, ammonia 5·2=100. Analyses: W. J. Taylor (l. c.):

	$\dddot{S}$	$\dot{Na}$	$\dot{K}$	NH^4O	
1.	48·40	1·68	43·45	5·37, org. matter	*tr.*=98·90.
2.	48·30	46·49		5·10, " "	*tr.*=99·89.

Pyr., etc.—B.B. on platinum foil blackens and fuses with difficulty, leaving a white bead, which is soluble in water and tastes a little saline and bitter. Heated in a platinum crucible becomes first black and then snow-white, not fusing at a high heat (Taylor).

Obs.—From the guano beds of the Chincha Islands.

An artificial sulphate of potash and alumina is described by Link as early as 1796, in Crell's Annalen, i. 29.

627. APHTHITALITE. Vesuvian Salt *Smithson*, Phil. Trans. R. Soc., 1813. Aphthalose *Beud.*, Tr., ii. 477, 1832. Aphthitalite, *Shepard*, Min., i. 36, 1835. Arcanite *Haid.*, Handb., 492, 1845. Glaserite *Hausm.*, Handb., 1847. Sulphate of Potash. Schwefelsaures Kali, Kalisulphat, *Germ.* Potasse sulfatée *Fr.*

Orthorhombic. $I \wedge I = 104° \; 52'$, $O \wedge 1\text{-}\bar{i} = 119° \; 46'$; $a : b : c = 1{\cdot}749 : 1 : 1{\cdot}3$. Observed planes: O, $1\text{-}\bar{i}$, $\frac{1}{3}\text{-}\bar{i}$, $i\text{-}\bar{i}$, $1\text{-}\breve{i}$, $\frac{1}{3}\text{-}\breve{i}$, $i\text{-}\breve{i}$, 1, $2\text{-}\breve{2}$. $O \wedge \frac{1}{3}\text{-}\bar{i} = 149° \; 46'$, $O \wedge \frac{1}{2}\text{-}\breve{i} = 146° \; 4'$, $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, basal, $= 120° \; 29'$, $1\text{-}\breve{i} \wedge 1\text{-}\breve{i}$, id., $= 106° \; 46'$, $\frac{1}{3}\text{-}\bar{i} \wedge \frac{1}{3}\text{-}\bar{i}$, id., $= 60° \; 28'$, $\frac{1}{2}\text{-}\breve{i} \wedge \frac{1}{2}\text{-}\breve{i} = 67° \; 52'$. Occurs in thin tables, and in blades made up of aggregated crystals; also massive, or imperfectly mammillary, and in crusts.

H.=3.–3·5. G.=1·731. Lustre vitreous, inclined to resinous. Color white, sometimes tinged with blue or green. Transparent to translucent, or opaque. Taste saline and bitter, disagreeable. Unalterable in the air.

Comp.—$\dot{K}\,\dddot{S}$=Potash 54·1, sulphuric acid 45·9=100. A specimen from Vesuvius contained Sulphate of potash 71·4, sulphate of soda 18·6, chlorid of sodium 4·6, chlorid of ammonium, copper, and iron 5·4=100 (Phil. Trans., 1813).

Pyr., etc.—Fuses before the blowpipe without intumescence. Soluble in water.

Obs.—Found at Vesuvius, upon lava, in delicate crystallizations, and also in masses an inch or more in thickness.

Named *aphthalose* by Beudant, in 1832, from ἄφθιτος, *unalterable*, and ἅλς, *salt*; and changed, by Shepard, to the less incorrect form from these Greek words, *aphthitalite*. *Glaserite* was used in the last edition of this work, a name given by Hausmann in 1847, after the chemist Christoph Glaser (1664), the salt having been early called *Sal polychrestum Glaseri*. But if aphthitalite is rejected, *Arcanite* of Haidinger (derived from one of its alchemistic names, *Arcanum duplicatum*) comes next in order of priority.

628. MISENITE. *A. Scacchi*, Mem. G. sulla Campania, 98, 1849.

In silky fibres of a white color. Soluble; taste acid and bitter.

Comp.—$\dot{K}\,\dddot{S}+\dot{H}\,\dddot{S}$. Analysis by Scacchi (l. c., J. pr. Ch., lv. 54):

$\dddot{S}$ 56·93 $\dot{K}$ 36·57 $\not{A}l$ 0·38 $\dot{H}$ 6·12=100.

Pyr., etc.—Fuses easily in the flame of a spirit lamp, imparting a violet color to it. Soluble in water.

Obs.—Occurs in a hot tufa cavern, near Misene.

629. THENARDITE. *J. L. Casaseca*, Ann. Ch. Phys., xxxii. 308, 1826. Anhydrous Sulphate of Soda. Pyrotechnite *Scacchi*, Mem. Incend. Vesuv. Napoli, 1855.

Orthorhombic. $I \wedge I = 103° \; 26'$, $O \wedge 1\text{-}\bar{i} = 120° \; 36'$, Hausmann; $a : b : c = 1{\cdot}6905 : 1 : 1{\cdot}267$, $O \wedge 1\text{-}\breve{i} = 126° \; 51'$, $1\text{-}\breve{i} \wedge 1\text{-}\breve{i}$, top, $= 73° \; 42'$, basal $= 106° \; 18'$, $1 \wedge 1 = 135° \; 41'$, $123° \; 43'$, $74° \; 18'$. Cleavage: basal, nearly perfect.

H.=2–3. G.=2·55, Streng; 2·73, Casaseca. Lustre vitreous. Color white to brown. Translucent.

Comp.—$\dot{Na}\,\dddot{S}$=Soda 56·3, sulphuric acid 43·7=100 Analyses: 1, Casaseca (l. c.); 2, A. Dick (Phil. Mag., IV. v. 373); 3, Streng (Jahrb. Min. 1863, 566):

	$\dddot{S}$	$\dot{Na}$	$\dot{K}$	$\dot{H}$	Cl	
1. Espartinas	99·78		—	—	—	, $\dot{Na}\ddot{C}$ 0·22=100 Casaseca
2. Tarapaca	55·11	42·37	—	—	—	, insol. 2·19=99·67 Dick.
3. Bolivia	54·31	41·52	0·46	0·60	0·01	, insol. 3·39=100·29 Streng.

Pyr., etc.—Colors the blowpipe flame deep yellow. Wholly soluble in water.

Obs.—Occurs in Spain, at Espartinas, 5 leagues from Madrid and 2½ from Aranjuez. The water exudes during winter from the bottom of a basin, and becoming concentrated in the summer season, deposits crystals of thenardite. Also in nitre plains of Bolivia; at Tarapaca, with glauberite and ulexite, the crystals of which locality give some of the angles nearly of trona, according to H. J. Brooke (l. c.). Also on the scoria of Vesuvius (*pyrotechnite*) of the eruption of 1855; on solution and evaporation, octahedral crystals were obtained by Scacchi having the planes I, $1\text{-}\bar{i}$, 1, $3\text{-}\breve{3}$, with $I \wedge I$=118° 37′, $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, over base,=128° 58′, 1 ∧ 1, basal,=135° 21′, pyramidal,=123° 39′, 74° 36′, $3\text{-}\breve{3} \wedge 3\text{-}\breve{3}$, basal,=158° 41′, pyramidal, 63° 48′, 123° 2′.

Kayser has analyzed an acicular saline efflorescence from a mine near Clausthal, and obtained (B. H. Ztg., xviii. 1859, No. 18) $\dot{Na}\dddot{S}$ 91—95·3, $\dot{Mg}\dddot{S}$ 1·6—4·0, $\dot{Fe}\dddot{S}$ 0·2, $\dot{Ca}\dddot{S}$ 1·6—1·8, with $\dot{H}$ 1—1·8.

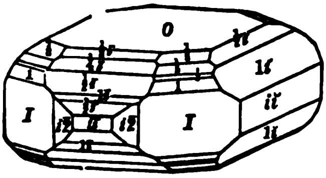
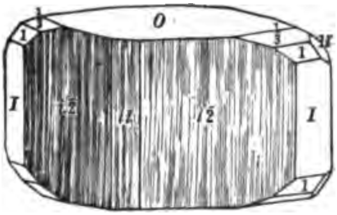
Crystals usually tabular, as in figures; sometimes prismatic in the direction of the vertical axis (f. 507). Cleavage: basal rather perfect; *I* somewhat less so; *i*-ĭ imperfect. Twins: plane of composition *i*-ĭ, the compound character being apparent in the striæ of the plane *O* Also in globular forms, fibrous or lamellar, crested; coarsely laminated, laminæ convergent and often curved; also granular; colors sometimes banded as in stalagmite.

506



Cheshire.

507



Virginia.

H.=2·5—3·5. G.=4·3—4·72; 4·4864, G. Rose, a pure colorless crystal. Lustre vitreous, inclining to resinous; sometimes pearly. Streak white. Color white; also inclining to yellow, gray, blue, red, or brown, dark brown. Transparent to translucent—opaque. Sometimes fetid, when rubbed. Optic-axial plane brachydiagonal.

Var.—1. *Ordinary.* (*a*) Crystals usually broad or stout; sometimes very large, weighing 100 lbs.; sometimes in slender needles. Dauber, after careful measurements, made $I \wedge I = 101^\circ\ 40'$, and $O \wedge \tfrac{1}{2}\text{-}\bar{i} = 141^\circ\ 6'$, varying but two minutes in the latter from former measurements (Pogg., cviii. 440). (*b*) *Crested;* massive aggregations of tabular crystals, the crystals projecting at surface into crest-like forms. (*c*) *Columnar;* the columns often coarse (*Stangenspath*) and loosely aggregated, and either radiated (*strahlbaryt*) or parallel; rarely fine fibrous. Werner's *stangenspath* was from Freiberg. (*d*) In globular or nodular concretions, subfibrous or columnar within. *Bologna Stone* is here included, being radiated, globular, often reddish-gray in color. It is from a bed of clay in Mt. Paterno, near Bologna, and was early a source of wonder because of the phosphorescence it exhibited after heating with charcoal. "Bologna phosphorus" was made from it in the form of sticks, by powdering the mineral and uniting it again with gum. (*e*) Lamellar, either (*a*) straight or (*b*) curved; the latter sometimes as aggregations of curved scale-like plates (the *krumschaliger Schwerspath* of Werner). (*f*) Granular. (*g*) Compact or cryptocrystalline. (*h*) Earthy. (*i*) Stalactitic and stalagmitic; similar in structure and origin to calcareous stalactites and stalagmites.

2. *Fetid;* so called from the odor given off when struck, which odor is due to carbonaceous matters present. (Anal. 6–8.)

3 *Allomorphite* Breith.; a kind having the form and cleavage of anhydrite, and found at Unterwirbach, near Rudolstadt, in Schwarzenburg; G.=4·36—4·48. Probably pseudomorphous; Breithaupt regards it as a case of dimorphism.

4. *Calcareobarite* Thomson (Min., i. 105) is a white barite from Strontian in Argyleshire, containing, probably as mixture, 6·6 p. c. of lime, and some silica and alumina. He found $\dddot{S}$ 35·23, $\dot{B}a$ 48·95, $\dot{S}r$ 0·79, $\dot{C}a$ 6·60, $\ddot{\bar{F}}e$ 0·45, $\ddot{S}i$ 4·14, $\ddot{\bar{A}}l$ 3·46, moisture 0·57=100·19; G.=4·1907. A part of the *krumschaliger Schwerspath* of Werner—specimens from Freiberg—is referred here by Breithaupt, who gives for $I \wedge I$ 101° 53′, and G.=4·02—4·29.

5. *Celestobarite;* the spar containing much sulphate of strontian, as that of Binnen valley, Switzerland (anal. 2), to which von Waltershausen applied the name *baryto-celestine*, and also that of anal. 3, 4. The angles of the Binnen spar, according to Hugard, are intermediate between those of barite and celestite.

6. *Calstronbarite*, from Schoharie, N. Y., has the aspect of a mere mixture. Shepard made it a compound (l. c.) of *carbonates* of strontia (22·30) and lime (12·15), with 65·55 p. c. of sulphate of baryta, and says it is partly *soluble in muriatic-acid with effervescence.* Von Hauer found a specimen from Schoharie labelled *calstronbarite* to consist of sulphates alone.

Cawk is the ordinary barite of the Derbyshire lead mines. Withering, who first analyzed it (Phil. Trans., lxxiv. 293, 1784), describes it as occurring in roundish forms, consisting of rhomboidal laminæ confusedly aggregated and white or reddish in color, with G.=4·330; and a second variety as radiated fibrous, somewhat silky in lustre, and at times concentric in structure, yellowish-white, and opaque, with G.=4·00. Greg & Lettsom (1858) confine the term to an opaque earthy variety of the Derbyshire lead mines.

The barite of Muszar, Hungary, and of Betler, near Rosenau, was early called *Wolnyn*. It is common barite, in crystals, usually oblong in the direction of the vertical axis, and generally with *i*-ī and *O* large, and also *i*-2̆ large. A. Schrauf mentions the following as other occurring planes *O*, 4-ĭ, 1-ĭ, ½-ī, ⅓-ī, 8-ĭ, 2-ĭ, 1-ĭ, 1, 2, 1-2̆, 2-2̆, 3-3̆, 4-4̆ (Ber. Ak. Wien, xxxix. 286). Leonhard says that at Muszar it occurs in the cavities of alumstone.

Comp.—$\dot{\mathrm{B}}\mathrm{a}\,\dddot{\mathrm{S}}$=Sulphuric acid 34·3, baryta 65·7. Sulphate of strontian and silica are often present, and sometimes sulphate of lime, clay, bituminous or carbonaceous substances. Analyses: 1, Stromeyer (Unters., 222); 2, Waltershausen (Pogg., xciv. 138); 3, Rammelsberg (Min. Ch., 259); 4, Jordan (Schw. J., lvii. 358); 5, Heidingsfeld (Ramm. 5th Suppl., 207); 6, 7, John (Unters., ii. 73, 69); 8, Klaproth (Beitr., v. 121):

G. of anal. 2=3·977; 4, 4·4888.

In pure colorless crystals from Silbach, of G.=4·4864 (Rose), Rammelsberg found no impurities except a trace of strontian (Min. Ch., 259). Freiesleben found 8 p. c. of silica in a variety from Nassau.

Allomorphite, according to Gerngross, contains 1·9 p. c. of sulphate of lime as impurity, but von Hauer found none (Jahrb. G. Reichs., 1853, 152).

Pyr., etc.—B.B. decrepitates and fuses at 3, coloring the flame yellowish-green; the fused mass reacts alkaline with test paper. On charcoal reduced to a sulphid. With soda gives at first a clear pearl, but on continued blowing yields a hepatic mass, which spreads out and soaks into the coal. If a portion of this mass be removed, placed on a clean silver surface, and moistened, it gives a black spot of sulphid of silver. Should the barite contain sulphate of lime, this will not be absorbed by the coal when treated in powder with soda. Insoluble in acids

Obs.—Occurs commonly in connection with beds or veins of metallic ores, as part of the gangue of the ore. It is met with in secondary limestones, sometimes forming distinct veins, and often in crystals along with calcite and celestite.

At Dufton, in Westmoreland, England, large transparent crystals occur, sometimes of gigantic dimensions; some were found lying in the mud at the bottom of a cavern, and one weighed 100 lbs. Other English localities exist in Cornwall, near Liskeard, etc., in Cumberland and Lancashire, in Derbyshire, Staffordshire, etc.; fine stalactitic at Newhaven in Derbyshire; in Scotland, in Argyleshire, at Strontian; in Perthshire, of a bright yellow color at Ballindean; at the Cumberland lead mine; in Ireland, in thick veins in old red sandstone, at Ballynascreen in Londonderry.

The septaria of Durham, England, which are cut and polished for tables, etc., have the veinings lined with brown heavy spar, adding much to their beauty. Some of the most important European localities are at Felsöbanya and Kremnitz, at Freiberg, Marienberg, Clausthal, Przibram, and at Roya and Roure in Auvergne.

In the United States, in *N. Hamp.*, at Piermont. In *Mass.*, at Hatfield and Leverett. In *Conn.*, at Cheshire, large crystals, sometimes transparent (f. 506, and simpler forms), intersecting in veins red sandstone with vitreous copper and green malachite; at Berlin, Farmington, and Southington. In *N. York*, at Pillar Point, opposite Sackett's Harbor, massive, 2–3 ft. thick, in compact limestone, affording large slabs, beautiful when polished; at Scoharie, a fibrous variety with calcite, the two often mechanically mingled; in St. Lawrence Co., fine tabular crystals in De Kalb, at Fowler with specular iron, at the Parish ore bed, and on the farm of J. Morse, in Gouverneur, with calcite and hematite, and on the banks of Laidlaw lake in Rossie; the crested variety at Hammond, with crystals of pyrite; at Wolcott, Wayne Co., near the stratum of lenticular iron ore, and on the S. side of the Mohawk, opposite Little Falls. In *Penn.*, in crystals at Perkiomen lead mine. In *Virginia*, at Eldridge's gold mine in Buckingham Co. (fig. 507); 3 m. S.W. from Lexington, in Rockbridge Co.; a beautiful white variety on the plantation of J. Hord, Esq. Fauquier Co. In *Kentucky*, near Paris, in a large vein. In *Tenn.*, on Brown's Creek; at Haysboro', near Nashville; in large veins in sandstone on the W. end of I. Royale, L. Superior, and on Spar Id., N. shore, one vein (containing also calcite) 14 ft. wide, sometimes in crystals; in trap of N shore, veins numerous. In *Canada*, a vein 27 in. wide at Landsdown, affording fine crystals In fine crystals near Fort Wallace, New Mexico.

The white varieties of barite are ground up and employed as a white paint, either alone or mixed with white lead.

For recent papers on cryst., see Dauber, l. c.; Pfaff, Pogg., cii. 464; Hessenberg, Min. Not., iii. and iv. Above, the cleavage prism is made the vertical *I*, as done by Phillips. Brooke and Miller, and many other authors, this position giving the simplest symbols. Naumann makes this prism the dome 1-ī, and *i*-ĭ the basal plane *O*, while *O* above is his *i*-ĭ. The planes following the order on page 616, are, in Naumann's position, as follows: *i*-ĭ; "vertical," 1-ī, *i*-ī, *O*, ⅔-ī, 2-ī, 4-ī, ⅜-ī, ½-ī, ⅓-ī; "macrodomes," *i*-8̆, *i*-6̆, *i*-5̆, *i*-4̆, *i*-3̆, *i*-2̆, *I*, *i*-3̄/2; "brachydomes," 8-ĭ, 2-ĭ, ⅝-ĭ, 1-ĭ; "octahedrons," 8-8̆, 6-6̆, 5-5̆, 4-4̆, 3-3̆, 2-2̆, 3/2-3̆/2, 1; 2, 3-3̄/2; 2-4̆, 1-2̆, ⅔-2̆.

Named from *βάρος*, *weight*, or *βαρυς*, *heavy*.

Alt.—Heavy Spar occurs altered to calcite, spathic iron, cerussite, quartz, limonite, red iron ore, pyrite, psilomelane, göthite.

631. CELESTITE. Fasriger Schwerspath [=Fibrous Heavy Spar] (fr. Frankstown, Pa.) *Schütz*, Beschr. Nordamer. Foss., 12, Leipz., 1791. 509

L. Erie.

Cleavage: *O* perfect; *I* distinct; *i*-ĭ less distinct. Also fibrous and radiated; sometimes globular; occasionally granular.

H.=3—3·5. G.=3·92—3·975; 3·9593, crystals, Beudant; 3·973, fr. Tharand, Breith.; 3·96, fr. Kingston, Hunt. Lustre vitreous, sometimes inclining to pearly. Streak white. Color white, often faint bluish, and sometimes reddish. Transparent—subtranslucent. Fracture imperfectly conchoidal—uneven. Very brittle. Trichroism sometimes very distinct.

Var.—1. *Ordinary.* (*a*) In crystals. The angle $I \wedge I$ varies much, and probably in part in consequence of the presence of some baryta or lime. It was made by Haüy 104° 48′, but with the common goniometer; by Kupffer, 104° 20′; by Phillips, 104°; by Mohs, 103° 58; by Websky, in an elaborate paper on crystals from Pschow in Upper Silesia (ZS. G., ix. 303), 103° 32′, and he suggests therefore that this mineral may contain lime or baryta; by Dauber, in very exact measurements of Sicily crystals (Pogg., cviii. 447), 104° 4′ 24″ to 104° 7′ 14″, with the deduced mean 104° 6′ 34″; and for the dome $1\text{-}\bar{i}$, 75° 45′ 43″; by Kokscharof (Min. Russl., v. 8) from Sicily crystals, 104° 3′ 46″, $O \wedge \frac{1}{2}\text{-}\bar{i} = 140° 36′$, his calculated results being 104° 3′ 50″ and 140° 35′.

(*b*) Fibrous, either parallel or radiated. (*c*) Lamellar; of rare occurrence. (*d*) Granular. (*e*) Concretionary. (*f*) Earthy; impure usually with carbonate of lime or clay.

2. *Calciocelestite.* Containing much lime.

3. *Barytocelestite*, or Baryto-sulphate of strontia of Thomson, from Drummond I., L. Erie, contains much baryta. Hugard gives for $I \wedge I$ in this Drummond I. variety 103½°, an angle intermediate between that of barite and celestite (see below).

Comp.—$\dot{Sr}\,\dddot{S}$=Sulphuric acid 43·6, strontia 56·4=100. Analyses: 1, Klaproth (l. c.); 2, Vauquelin (l. c.); 3, 4, 6, 7, Stromeyer (Untors., 203); 5, Maddrell (Ramm. Min. Ch., 260); 8, R. Brandes (Schw. J., xxi. 177); 9, v. Hauer (Jahrb. G. Reichs., iv. 397); 10, Schmid (Pogg., cxx. 637):

10. Erfurt	43·68	53·59	0·51	1·26	0·28=99·12 Schmid.

Wicke found in celestite from a stratum of clay near Wassel—the *calciocelestine* (Arch. d. Pharm., clii. 32)—$\dot{Sr}\,\dddot{S}$ 91·464, $\dot{Ca}\,\dddot{S}$ 8·313, $\dot{Fe}$ 0·003=99·780; G.=4·020. It may be only a mixture.

Thomson gives for the composition of the Drummond I. celestite—*barytocelestite* (l. c.)—$\dddot{S}$ 40·26, $\dot{Sr}$ 35·72, $\dot{Ba}$ 23·06, $\dot{Fe}$ 0·59, $\dot{H}$ 0·72=100·29, and G.=3·921. But his analysis needs confirmation. The celestite of Kingston, C. W., which Thomson ranks with that of Drummond I., is pure celestite according to T. S. Hunt; it has G.=3·96. In the radiated mineral from Nörten, Hanover, Turner found (Ed. Phil. J., ii. 329) $\dot{Sr}\,\dddot{S}$ 78·21, $\dot{Ba}\,\dddot{S}$ 20·41=98·62; and Grüner (Gilb. Ann., lx. 72) $\dot{Sr}\,\dddot{S}$ 73·00, $\dot{Ba}\,\dddot{S}$ 26·17, who analyzed crystals of a bluish milk-white color, having G.=3·9506.

Wittstein finds that the blue color of the celestite of Jena is due to a trace of a phosphate of iron.

Pyr., etc.—B.B. frequently decrepitates, fuses at 3 to a white pearl, coloring the flame strontia-red; the fused mass reacts alkaline. On charcoal fuses, and in R. F. is converted into a difficultly fusible hepatic mass; this treated with muriatic acid and alcohol gives an intensely red flame. With soda on charcoal reacts like barite. Insoluble in acids.

Obs.—Celestite is usually associated with limestone, or sandstone of Silurian, Devonian, Jurassic, and other geological formations. Occurs also in beds of gypsum, rock salt, and clay; and with sulphur in some volcanic regions.

Sicily, at Girgenti and elsewhere, affords splendid groups of crystals along with sulphur and gypsum. Fine specimens are met with at Bex in Switzerland, and Conil in Spain; at Dornburg, near Jena, fibrous and bluish; in the department of the Garonne, France; in the Tyrol; Retzbanya, Hungary; at Nörten, in Hanover; in rock salt, at Ischl, Austria. Also found at Aust Ferry, near Bristol; in trap rocks near Tantallan, in East Lothian; at the Calton Hill, Edinburgh; near Knaresborough, in Yorkshire; at Popayan, New Grenada.

Specimens, finely crystallized, of a bluish tint, are found in the Trenton limestone about Lake Huron, particularly on Strontian Island, and at Kingston in Canada; Chaumont Bay, Schoharie, and Lockport, N. Y., have afforded good specimens; also the Rossie lead mine; Depauville and Stark (farm of James Coill), N. Y. A blue fibrous celestite occurs near Frankstown, Logan's Valley, Huntington Co., Penn., associated with pearl spar and anhydrite, and this was the celestite taken to Europe by Schütz, and named by Werner after an analysis by Klaproth.

The dark blue fibrous celestite of Jena is peculiarly trichroic; and its color also varies with the angle between the principal cleavage and the direction of the fibres; the color with the angle 86°, dark blue; 67°, sky blue; 46°, pale blue (Schmid, Pogg., cxx. 637).

Named from *cælestis, celestial*, in allusion to the faint shade of blue often presented by the mineral.

Artif.—Obtained in crystals at a temperature of 300° C. from solution in water (Dr. Sullivan); in lamellar crystals by fusing a mixture of gypsum and common salt, and treating with water A. Gages.

Fig. 511 view of front side of a thick, rectangular, somewhat tabular crystal, having a zone of planes between $i\text{-}\bar{i}$ and each $1\text{-}\breve{i}$, or the corresponding edge. Cleavage: $i\text{-}\bar{i}$ very perfect; $i\text{-}\breve{i}$ also perfect; O somewhat less so. Also fibrous, lamellar, granular, and sometimes impalpable. The lamellar and columnar varieties often curved or contorted.

H. = 3 – 3·5. G. = 2·899–2·985; 2·956, Aussee; 2·985, Stassfurt. Lustre: $i\text{-}\breve{i}$ and $i\text{-}\bar{i}$ somewhat pearly; O vitreous; in massive varieties, vitreous inclining to pearly. Color white, sometimes a grayish, bluish, or reddish tinge; also brick-red. Streak grayish-white. Fracture uneven; of finely lamellar and fibrous varieties, splintery. Optic-axial plane parallel to $i\text{-}\bar{i}$, or plane of most perfect cleavage; bisectrix normal to O; Grailich.

Var.—1. *Ordinary.* (*a*) Crystallized; cleavable in its three rectangular directions. (*b*) Fibrous; either parallel, or radiated or plumose. (*c*) Fine granular. (*d*) Scaly granular. *Vulpinite* is a scaly granular kind from Vulpino in Lombardy; it is cut and polished for ornamental purposes. It does not ordinarily contain more silica than common anhydrite. A kind in contorted concretionary forms is the tripestone (*Gekrösstein*).

2. *Pseudomorphous*; in cubes after rock salt.

Comp.—$\dot{C}a\ \dddot{S}$=Lime 41·2, sulphuric acid 58·8=100. Analyses: 1, Klaproth (Beitr., iv. 224) 2–4, Stromeyer (Schw. J., xiv. 375); 5, C. W. C. Fuchs (B. H. Ztg., xxi. 198):

	$\dddot{S}$	$\dddot{S}i$	$\dot{F}e$	$\dot{C}a$	$\dot{H}$	
3. *Vulpinite, coarse*	56·77	0·26	0·03	41·40	0·94=99·40	Stromeyer.
4. " *fine*	58·01	0·09	—	41·70	0·07=99·86	Stromeyer.
5. Stassfurt, *cryst.*	58·86	—	—	40·21	0·65=99·72	Fuchs.

Vauquelin made the vulpinite to contain 8 p. c. of silica (and hence the name siliceous anhydrite), which the later analyses do not sustain.

Pyr., etc.—B.B. fuses at 3, coloring the flame reddish-yellow, and yielding an enamel-like bead which reacts alkaline. On charcoal in R.F. reduced to a sulphid; with soda does not fuse to a clear globule, and is not absorbed by the coal like barite; is, however, decomposed, and yields a mass which blackens silver; with fluorite fuses to a clear pearl, which is enamel-white on cooling, and by long blowing swells up and becomes infusible. Soluble in muriatic acid.

One hundred parts of water, at 18·75° C., dissolve 0·2 part of anhydrite.

Obs.—Occurs in rocks of various ages, especially in limestone strata, and often the same that contain ordinary gypsum, and also very commonly in beds of rock salt. It was first discovered at the salt mine near Hall in Tyrol, by Abbé Poda; and next that of Bex, Switzerland. Other localities are at Aussee, both crystallized and massive, the former sometimes in splendid geodes (f. 511), the latter brick-red; at Sulz on the Neckar, in Würtemberg; Himmelsberg, near Ilfeld; Bleiberg in Carinthia; Lüneburg, Hanover; Lauterberg in the Harz; Kapnik in Hungary; Ischl in Upper Austria; Aussee in Styria; Berchtesgaden in Bavaria; at Rienthal and elsewhere in the Alps, crystals, or their cavities, within quartz crystals; Stassfurt, in fine crystals.

In the U. States, at Lockport, N. Y., fine blue, in geodes of black limestone, accompanied with crystals of calcite and gypsum. In Nova Scotia it forms extensive beds at the estuary of the Avon and the St. Croix rivers, also near the Five Islands and elsewhere, associated with gypsum, in the Carboniferous formation.

A crystal from Hall, figured by Haüy, was a stout rectangular prism, with planes I on the lateral edges, giving $i\text{-}\bar{i} \wedge I=140°\ 4'$, whence $I \wedge I=100°\ 8'$. The Stassfurt crystals (f. 510, Blum, Jahrb. Min. 1865, 601) have nearly the ordinary forms of barite, and approximate to them in angles. Schrauf makes the angle over $i\text{-}\bar{i}$ of an occurring vertical prism (Pogg., cxvii. 650, 1862) 120°, and v. Rath (Ber. nied. Ges. Bonn, 201, 1862) 121° 24′. Blum states that the prism I is the most common; it is vertically striated, and these striations are formed of planes of the other vertical prisms measured by him; measurements only approximations. Schrauf and Blum make the angle $1\text{-}\breve{i} \wedge 1\text{-}\breve{i}=85°$; Fuchs (B. H. Ztg., xxi. 198), 84½°; and v. Rath, 84° 34′. In fig. 511 the plane *o* is in the same vertical zone with *s*; and if *o* is made the plane 1 (as done by Brooke and Miller), *n* is $2\text{-}\breve{2}$, and *f* $3\text{-}\breve{3}$. B. and M. obtained in their measurements for $i\text{-}\bar{i}$ on *f*, *n*, *o*, 153° 14′, 148° 41′, and 123° 31′ (Phil. Mag., III. 19, 178); and Grailich and Lang, for the same (Ber. Ak. Wien, xxvii. 25), 153° 50′, 143° 37′, 124° 10′. The latter give for their calculated results, 153° 18½′, 142° 59½′, 123° 32½′. The prism $i\text{-}\breve{\tfrac{3}{2}}$, which has the angle 102° 34′, may be that homologous with I of barite; in this case the brachydiagonal above would be the macrodiagonal.

Alt.—Absorbs moisture and changes to gypsum. Extensive beds are sometimes thus altered in part or throughout, as at Bex, in Switzerland, where, by digging down 60 to 100 ft., the unaltered anhydrite may be found. Sometimes specimens of anhydrite are altered between the folia or over the exterior. Also altered to quartz and siderite.

Crystals sometimes tabular; often oblong prismatic, and in the direction of either of the axes; as the vertical axis in f. 515; the macrodiagonal in f. 512, 516; the brachydiagonal in f. 513; also thick and short, as in f. 514; also sometimes in octahedral forms, more or less modified, made principally of planes 1-2̆, as in f. 517; or of planes 1; or 1-3̆, or 1-4̆. Cleavage: I, O, but interrupted. The planes I and i-ī often vertically striated, and ½-ī horizontally. Also massive, granular, or hardly so. Sometimes stalactitic.

H.=2·75–3. G.=6·12–6·39; 6·35, Phenixville, Smith. Lustre highly adamantine in some specimens, in others inclining to resinous and vitreous. Color white, tinged yellow, gray, green, and sometimes blue. Streak uncolored. Transparent—opaque. Fracture conchoidal. Very brittle.

Comp.—$\dot{\mathrm{P}}\mathrm{b}\,\dddot{\mathrm{S}}$=Sulphuric acid 26·4, oxyd of lead 73·6=100. Analyses: 1, 2, Klaproth (Beitr., iii. 162); 3, Stromeyer (Untera., 226); 4, Thomson (Min., i. 559); 5, J. L. Smith (Am. J. Sci., II xx. 244):

	$\dddot{S}$	$\dot{P}b$	$\bar{F}e$	$\dot{H}$
1. Wanlockhead	25·75	70·50	——	2·25=98·50 Klaproth.
2. Anglesea	24·8	71·0	1·0	2·0=98·8 Klaproth.
3. Zellerfeld	26·09	72·47	$\bar{F}e\dot{H}^3$ 0·09	0·51, $\bar{M}n$ 0·07=99·23 Strom.
4. Leadhills	25·65	74·05	——	0·30=100 Thomson.
5. Phenixville	(½) 26·69	73·26	——	——, $\dddot{S}i$ 0·20=99·95 Smith.

Pyr., etc.—B.B. decrepitates, fuses in the flame of a candle (F.=1·5). On charcoal in O.F. fuses to a clear pearl, which on cooling becomes milk-white; in R.F. is reduced with effervescence to metallic lead. With soda on charcoal in R.F. gives metallic lead, and the soda is absorbed by the coal; when the surface of the coal is removed and placed on bright silver and moistened with water it tarnishes the metal black. Difficultly soluble in nitric acid. Soluble in citrate of ammonia (J. L Smith). Soluble in 22,816 parts of water of 11° C (Fresenius). Soluble 1 part in 30,062 of water (Rodwell).

Obs.—This ore of lead was first observed by Monnet as a result of the decomposition of galenite, and it is often found in its cavities. At Leadhills it occurred, occupying the cubical cavities of galenite, or disposed on the surface of the ore; and this locality, and also that of Wanlockhead, formerly afforded large and beautiful crystals, some transparent and several inches in diameter. First found in England at Parys mine in Anglesea. Occurs also at Melanoweth in Cornwall; in Derbyshire and in Cumberland in crystals; Clausthal, Zellerfeld, and Giepenbach, in the Harz; near Siegen in Prussia; Schapbach in the Black Forest, Badenweiler in Breisgau; and in Sardinia in small but perfect transparent crystals; Fondon in Granada; massive in Siberia, Andalusia, Alston Moor in Cumberland; in Australia, whence it is exported by the ton to England.

In the United States it occurs in large crystals at Wheatley's mine, Phenixville, Pa. (f. 512, 513, 514); less well crystallized in Missouri lead mines; at the lead mine of Southampton, Mass.; at Rossie, N. Y.; with galenite at the Walton gold mine, Louisia Co., Va.

Named from the locality, Anglesea, where it was first found by Dr. Withering.

For recent papers on cryst., Kokscharof, Min. Russl., i. 34, ii. 167, iii. 243, elaborate; v. Lang, Ber. Ak. Wien, very elaborate; Zepharovich, Ber. Ak. Wien, v. i. 369.

Sardinian is distorted anglesite from Monteponi in Sardinia, with which Richter found it to agree in composition; G.=6·380—6·392; H.=3—3·5; white and like anglesite in lustre. Breithaupt makes it hemidomatic (monoclinic or hemihedral); and found for the fundamental prism the angle 101° 52′; and says that the bisectrix of the optical angle is normal to a plane truncating an edge of the fundamental prism, and not to the base as in anglesite. The optical fact stated shows that the prism is normally orthometric; and if the plane referred to be made the base (or plane *O*) then the mineral agrees with anglesite, both crystallographically and optically. The so-called fundamental prism is prism $\tfrac{1}{2}$-$\bar{i}$ of anglesite, which has the angle, as above given, 101° 14′. The form approaches fig. 516 above.

Alt.—Anglesite occurs altered to cerussite ($\dot{P}b\ddot{C}$); also to a hydrous anglesite, according to Breith.

634. ZINKOSITE. Zinkosit *Breith.*, B. H. Ztg., xi. 100, 1852. Anhydrous Sulphate of Zinc

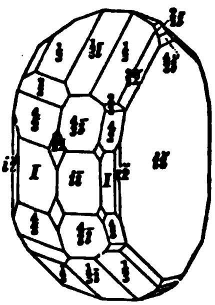
According to Breithaupt, this sulphate occurs at the mine of Barranco Jaroso in the Sierra Almagrera, Spain, in crystals isomorphous with anglesite and barite. Doubtful. G.=4·331.

635. LEADHILLITE. Plomb carbonaté rhomboidal *Bourn.*, Cat., p. 343, 1817. Sulphato-tricarbonate of Lead *Brooke*, Ed. Phil. J., iii. 117, 1820. Leadhillite *Beud.*, Tr., ii. 366, 1832. Bleisulphotricarbonat, Ternärbleierz, *Weiss.* Psimythit *Glocker*, Syn., 256, 1847.

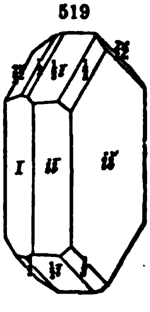
Orthorhombic. $I \wedge I=103° 16'$, $O \wedge 1\text{-}\bar{i}=120° 10'$; $a:b:c=1{\cdot}7205:1:1{\cdot}2632$. Observed planes as in f. 518, with also $i\text{-}2$ replacing edge between I and $i\text{-}\bar{i}$. Hemihedral in I and some other planes; hence monoclinic in aspect, or rhombohedral when in compound crystals.

$O \wedge \tfrac{1}{2}\text{-}\bar{i}=150° 10'$ $\quad$ $i\text{-}\bar{i} \wedge \tfrac{1}{4}\text{-}\bar{i}=156° 27'$ $\quad$ $i\text{-}\breve{i} \wedge I=128° 22'$
$O \wedge \tfrac{1}{2}=126\ 11$ $\quad$ $i\text{-}\breve{i} \wedge \tfrac{1}{2}\text{-}2=128\ 14$ $\quad$ $i\text{-}\breve{i} \wedge i\text{-}2=111\ 36$
$i\text{-}\bar{i} \wedge \tfrac{1}{2}\text{-}\bar{i}=119\ 50$ $\quad$ $i\text{-}\breve{i} \wedge \tfrac{1}{2}=111\ 30$ $\quad$ $i\text{-}\breve{i} \wedge i\text{-}\bar{i}=90$

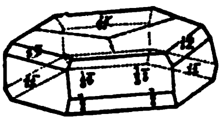
518



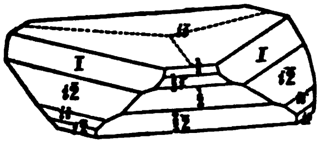
519



520



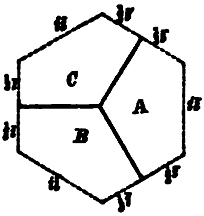
521



Cleavage: i-$\breve{i}$ very perfect; i-$\bar{i}$ traces. Twins, f. 520, 521 (drawn with i-$\breve{i}$ as top plane), consisting of 3 crystals; composition-face, 1-$\bar{i}$ (see f. 522); also parallel with I.

H.=2·5. G.=6·26–6·44. Lustre of i-$\breve{i}$ pearly, other parts resinous, somewhat adamantine. Color white, passing into yellow, green, or gray. Streak uncolored. Transparent—translucent. Conchoidal fracture scarcely observable. Rather sectile.

522



Comp.—$\dot{P}b\,\dddot{S}+3\,\dot{P}b\,\ddot{C}$=Sulphate of lead 27·45, carbonate of lead 72·55=100. Analyses 1, Berzelius (Jahresb., iii. 134); 2, Stromeyer (Gel. Anz. Gött., 113, 1825):

		$\dot{P}b\,\dddot{S}$	$\dot{P}b\,\ddot{C}$	
1.	Leadhills	28·7	71·0=99·7	Berzelius.
2.	"	28·3	72·7=100	Stromeyer.

Pyr., etc.—B.B. intumesces, fuses at 1·5, and turns yellow; but white on cooling. Easily reduced on charcoal. With soda affords the reaction for sulphuric acid. Effervesces briskly in nitric acid, and leaves white sulphate of lead undissolved.

Obs.—This ore has been found at Leadhills, with other ores of lead; also in crystals at Red Gill, Cumberland, and near Taunton in Somersetshire. Grenada is also stated to be a locality of it, and the island of Serpho, Grecian Archipelago. The crystals seldom exceed an inch in length, and are commonly smaller. Reported by C. U. Shepard (Am. J. Sci., II. xv. 446) from Newberg District, S. C., but there is some doubt as to the locality; also from the Morgan silver mine, Spartanburg District, S. C.

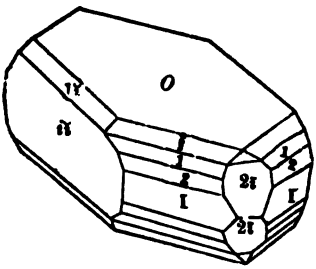
Brooke and Miller, who show that the form of leadhillite is orthorhombic, make the prism $\frac{1}{2}$-$\bar{i}$ (of 120° 20′) the fundamental vertical prism, and appear to regard the species as related to aragonite. The fact that the twins are not formed parallel to the faces of this prism (as they should be if the prism $\frac{1}{2}$-$\bar{i}$ were homologous with the aragonite prism), and the close approximation in angle to anglesite, shown above, besides other reasons, have led the author to adopt the position of the crystals here given, which exhibits the anglesite relation. Susannite (rhombohedral) and leadhillite (orthorhombic) are mutually dimorphs, and so also are dreelite and anglesite. Now susannite and dreelite are nearly identical in angle; and therefore leadhillite and anglesite must be equally related. Since in susannite the sulphuric acid dominates over the carbonic acid, and impresses on the lead salt its character (or the form of the sulphate), the same should be the case with its correlate leadhillite—this species being the very same chemical compound. (See on this subject, Am. J. Sci., II. xviii.). The hemihedrism of the species gives origin to the peculiar rhombohedral aspect of the twins. The angles of these twins are near those of susannite. Fig. 1 is partly from Mohs, with other occurring planes, and is introduced to show the relations of the planes in the position of the crystal adopted.

On crystallization, Haidinger, Ed. Phil. Trans., x. 217; B. & M., Min., 563.

636. CALEDONITE. Cupreous Sulphato-Carbonate of Lead *Brooke*, Ed. Phil. J., iii. 117, 1820. Calédonite *Beud.*, Tr., ii. 367, 1832.

Orthorhombic. $I \wedge I = 95°$, $O \wedge 1\text{-}\bar{i} = 123° 9'$; $a : b : c = 1{\cdot}5314 : 1 : 1{\cdot}0913$. Observed planes as in the annexed figure. $O \wedge 1\text{-}\breve{i} = 125° 29'$, $O \wedge 2\text{-}\bar{i} = 108° 5'$, $O \wedge \frac{1}{2} = 125° 50'$, $O \wedge 1 = 115° 43'$, $I \wedge i\text{-}\breve{i} = 132° 30'$, $1 \wedge 1$, pyr., $= 105°$ and $96° 45'$. Cleavage: I and O indistinct, $i\text{-}\breve{i}$ more obvious. Crystals sometimes large; usually minute; occasionally in divergent groups.

523



H.=2·5–3. G.=6·4. Lustre resinous. Color deep verdigris- or bluish-green; inclining to mountain-green if the crystals are delicate. Streak greenish-white. Translucent. Fracture uneven. Rather brittle.

Comp.—Sulphate of lead combined with carbonate of copper and lead. Analysis by Brooke (l. c.):

$\dot{\mathrm{P}}\mathrm{b}\,\bar{\mathrm{S}}$ 55·8 $\dot{\mathrm{P}}\mathrm{b}\,\ddot{\mathrm{C}}$ 32·8 $\dot{\mathrm{C}}\mathrm{u}\,\ddot{\mathrm{C}}$ 11·4=100 Brooke,

corresponding nearly to $3\,\dot{\mathrm{P}}\mathrm{b}\,\bar{\mathrm{S}} + 2\,\dot{\mathrm{P}}\mathrm{b}\,\ddot{\mathrm{C}} + \dot{\mathrm{C}}\mathrm{u}\,\ddot{\mathrm{C}}$, or $1\frac{1}{2}\,\dot{\mathrm{C}}\mathrm{u}\,\ddot{\mathrm{C}}$.

Pyr., etc.—B.B. on charcoal easily reduced. Partially soluble, with a slight effervescence, in nitric acid, leaving a residue of sulphate of lead (Brooke).

Obs.—Occurs at Leadhills, Scotland, accompanying other ores of lead, in crystals with linarite; at Red Gill in Cumberland; also at Retzbanya in Hungary; Tanné in the Harz. Said to occur at Mine la Motte, Missouri. The above figure is by Brooke of a Leadhills crystal.

637. DREELITE. Dréelite *Dufrénoy*, Ann. Ch. Phys., lx. 102, 1835. Dreeit *Glocker*, Syn., 261, 1847.

Rhombohedral. $R \wedge R = 93°$ or $94°$. Cleavage: rhombohedral, in traces.

H.=3·5. G.=3·2–3·4. Lustre pearly; splendent on a surface of fracture. Streak and color white.

Comp.—$\dot{\mathrm{C}}\mathrm{a}\,\bar{\mathrm{S}} + 3\,\dot{\mathrm{B}}\mathrm{a}\,\bar{\mathrm{S}}$. Analysis by Dufrénoy (l. c.):

$\dot{\mathrm{B}}\mathrm{a}\,\bar{\mathrm{S}}$ 61·73 $\dot{\mathrm{C}}\mathrm{a}\,\bar{\mathrm{S}}$ 14·275 $\dot{\mathrm{C}}\mathrm{a}\,\ddot{\mathrm{C}}$ 8·05 $\dddot{\mathrm{S}}\mathrm{i}$ 9·71 $\bar{\mathrm{A}}\mathrm{l}$ 2·405 $\dot{\mathrm{C}}\mathrm{a}$ 1·52 $\dot{\mathrm{H}}$ 2·31=100.

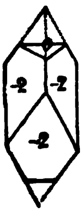
Obs.—In small unmodified crystals, disseminated on the surface and in the cavities of a quartzose rock, at Beaujeu, France, Dept. of the Rhone; also at Badenweiler (Baden).

Named by Dufrénoy after Mr. de Drée, a liberal patron of science.

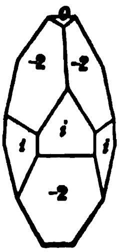
Thomson has analyzed another compound of the sulphates of baryta and lime (Min., i. 106), consisting of 71·9 of the former to 28·1 of the latter; it was from Harrowgate in Yorkshire.

638. SUSANNITE. Sulphato-tricarbonate of Lead pt. (fr. Susanna mine, Leadhills) *Brooke*, Ed. N. Phil. J., iii. 117, 188, 1827. Suzannit *Haid.*, Handb., 505, 1845.

524



525



Rhombohedral. $R \wedge R = 94°$, $O \wedge R = 128° 3'$; $a = 1{\cdot}1062$. Observed planes: -2, O, i, 2, 4, $-1\text{-}4$. $O \wedge 2 = 111° 13'$, $O \wedge 4 = 101° 30'$, $2 \wedge 2 = 72° 30'$. Cleavage: O easily obtained.

H.=2·5. G.=6·5–6·55. Lustre resinous—adamantine. Color white, green, yellow, brownish-black. Streak uncolored.

Comp.—Same as for leadhillite. Analysis by Brooke (l. c.) Sulphate of lead 27·5, carbonate of lead 72·5.

Crystals from Nertschinsk, analyzed by Kotschubey, having G.

=6·526—6·55, and therefore probably susannite rather than leadhillite, afforded him (Koksch. Min. Russl., 76, 1853) $\dot{P}b\,\dddot{S}$ 27·05, $\dot{P}b\,\ddot{C}$ 74·26=101·31; and $\dot{P}b\,\dddot{S}$ 26 91, $\dot{P}b\,\ddot{C}$ 72·87=99·78.

Obs.—In attached crystals at the Susanna mine, Leadhills in Scotland, at Moldawa in Hungary; Nertschinsk in Siberia. Formerly referred to leadhillite, the compound crystals of which it resembles.

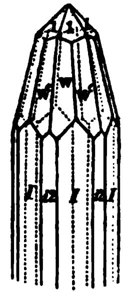
The rhombohedron *R* of susannite, as it is assumed by Haidinger, equals very nearly −2 of dreelite, which it is here made.

•

639. CONNELLITE. Copper Ore of an azure blue color, composed of needle crystals (fr. Wheal Providence) *Rashleigh*, Brit. Min., ii. 13, pl. 12, f. 1, 6, 1802. Sulphato-chloride of Copper *Connel*, Rep. Brit. Assoc., 1847. Connellite *Dana*, Min., 528, 1850.

Hexagonal. $O \wedge 1$=126° 50′; a=1·1562. Observed planes as in the annexed figure. From the measurements of Maskelyne, $w=\frac{12}{3}\text{-}\frac{12}{11}$. Crystals slender, or acicular; like f. 526; and also hexagonal prisms (i-2), with the pyramid 1.

527



Wheal Unity ?

$1 \wedge 1$, ov. summit,=73° 40′
$1 \wedge I$=143 10

$w \wedge i$-2=156 2
$w \wedge I$=166 54
$w \wedge 1$=152 37
$I \wedge i$-2=150

Lustre vitreous. Color fine blue. Translucent.

Comp.—From trials by Connell, contains oxyd of copper, sulphuric acid, and chlorid of copper, and supposed to be a compound of a sulphate and chlorid of copper.

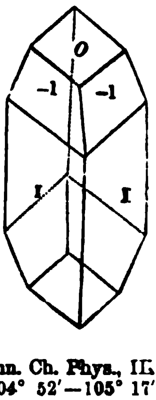
Easily soluble in nitric or muriatic acid.

Obs.—In Cornwall, at Wheal Unity and Wheal Damsel, in slender crystals, not over $\frac{1}{100}$ in. in diameter and $\frac{1}{10}$ in. thick; Maskelyne, Phil. Mag., IV. xxv. 39, whence the above figure.

640. GLAUBERITE. Glauberite *Brongniart*, J. d. M., xxiii. 5, 1808. Brongniartin *v. Leonh.* Handb., 270, 1826.

Monoclinic. C=68° 16′, $I \wedge I$=83° 20′, $O \wedge 1$-$\grave{\imath}$=136° 30′; $a : b : c$=0·8454 : 1 : 0·8267. Observed planes: O; vertical, I, i-i; hemidomes, 2-i, $\frac{2}{3}$-i; hemioctahedral, $\frac{1}{3}$, $\frac{1}{2}$, 1, 3, −1; 3-3.

528



$O \wedge i$-i=111° 44′
$O \wedge 1$=136 49
$O \wedge 3$=88 57
$O \wedge I$=104 15

−1 ∧ −1=116° 20′
$1 \wedge 1$=95 22
3-3 ∧ 3-3=136 8

Cleavage: O perfect.

H.=2·5—3. G.=2·64—2·85. Lustre vitreous. Color pale yellow or gray; sometimes brick-red. Streak white. Fracture conchoidal; brittle. Taste slightly saline.

Var.—The above angles are from Brooke & Miller. Senarmont found (Ann. Ch. Phys., III. xxxvi. 157) $I \wedge I$=82° 36′—83° 15′, $O \wedge 1$=137° 37′, $O \wedge 3$=89° 6′, $O \wedge I$=104° 52′—105° 17′, −1 ∧ −1=116° 18′—116° 52′, 3-3 ∧ 3-3=135° 20′.

Comp.—$(\frac{1}{2}\dot{\text{N}}\text{a}+\frac{1}{2}\dot{\text{C}}\text{a})\dddot{\text{S}}$=Sulphate of soda 51·1, sulphate of lime 48·9=100; or, Sulphuric acid 57·5, lime 20·1, soda 22·4. Analyses: 1, Brongniart (l. c.); 2, v. Kobell (Gel. Anz. München, Jahrb. Min. 1846, 840); 3, v. Hauer (Ber. Ac. Wien); 4, Hayes (J. Nat. H. Soc. Bost., iv. 498); 5, Ulex (Ann. Ch. Pharm., lxx. 51); 6, Pisani (C. R., li. 731):

	$\dddot{\text{S}}$	$\dot{\text{C}}\text{a}$	$\dot{\text{N}}\text{a}$	Cl	$\overline{\text{F}}\text{e}$
1. Villa Rubia	56·5	20·2	28·3	——	——=100 Brongniart.
2. Berchtesgaden	57·29	21·04	21·27	——	——=99·60 Kobell.
3. Ischl	57·52	20·37	21·87	0·31	——=100·07 Hauer.
4. Tarapaca	57·22	20·68	21·32	——	0·14=99·36 Hayes.
5. "	55·0	19·6	21·9	——	——, $\dddot{\text{B}}$ 3·5=100 Ulex.
6. Varengeville		$\dot{\text{N}}\text{a}\dddot{\text{S}}$ 50·50		$\dot{\text{C}}\text{a}\dddot{\text{S}}$ 48·78	clay 0·40=99·68 Pisani.

No. 5 was mixed with some ulexite; No. 6 was brick-red, friable, and resin-like.

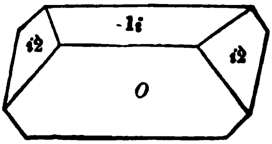
Pyr., etc.—B.B. decrepitates, turns white, and fuses at 1·5 to a white enamel, coloring the flame intensely yellow. On charcoal fuses in O.F. to a clear bead; in R.F. a portion is absorbed by the charcoal, leaving an infusible hepatic residue. With soda on charcoal gives the reaction for sulphuric acid. Soluble in muriatic acid. In water it loses its transparency, is partially dissolved, leaving a residue of sulphate of lime and in a large excess this is completely dissolved. On long exposure absorbs moisture and falls to pieces.

Obs.—In crystals in rock salt at Villa Rubia, near Ocana, in New Castile; also at Aussee, in Upper Austria; in Bavaria; at the salt mines of Vic, in France ($O \wedge I$=104° 11′, Dufr.); at Varengeville, near Nancy, a red variety in salt with polyhalite and anhydrite; and at Borax Lake, California, in blue clay, at a depth of 40 ft., having been obtained in an Artesian boring. Province of Tarapaca, Peru (affording the above figure and Senarmont's angles), with ulexite.

Artif.—On the artificial preparation of glauberite, J. Fritzsche, J. pr. Ch., lxxii. 291. On cryst., Senarmont, Ann. Ch. Phys., III. xxxvi. 157.

641. LANARKITE. Sulphato-Carbonate of Lead *Brooke*, Ed. Phil. J., iii. 117, 1820. Lanarkite *Beud.*, Tr., ii. 366, 1832. Dioxylith *Breith.*, Char., 1832. Kohlenvitriolbleispath, Halbvitriolblei, *Germ.*

529



Monoclinic. $I \wedge I$=85° 48′; i-$\grave{2} \wedge i$-$\grave{2}$, front,=49° 50′, Greg; $O \wedge -1$-i=120° 45′. Plane i-$\grave{2}$ usually rounded, and the crystals aggregated lengthwise, and seldom distinct. Cleavage: O perfect; -1-i less perfect. Laminæ flexible as in gypsum.

H.=2—2·5. G.=6·3—7; 6·3—6·4, Thomson. Lustre of the cleavage-face pearly; other parts adamantine, inclining to resinous. Streak white. Color greenish-white, pale yellow, or gray. Transparent—translucent.

Comp.—$\dot{\text{P}}\text{b}\dddot{\text{S}}+\dot{\text{P}}\text{b}\ddot{\text{C}}$=Sulphate of lead 53·15, carbonate of lead 46·85. Analyses: 1, Brooke (l. c.); 2, Thomson (Phil. Mag., III. xv. 402):

1. Carbonate of lead 46·9 Sulphate of lead 53·1=100.
2. " " 46·04 " " 43·96=100; G.=6·3197.

Pyr., etc.—B.B. on charcoal easily reduced. Partially dissolved in nitric acid with effervescence, leaving a residue of sulphate of lead (Brooke).

Obs.—At Leadhills, Lanarkshire, Scotland, with caledonite and susannite; of very rare occurrence. Massive in Siberia, and at Tanne, in the Harz; at Biberweier, Tyrol.

$O(c) \wedge 1\text{-}i\ (s)$		138 14—138 9	
$O(c) \wedge 3\text{-}i\ (x)$		97 44—97 35	
$O(c) \wedge I(m)$			99 11—99

From his numerous exact measurements he deduces for the angle C, or the inclination of the axis, in the Brazilian, 77° 14′ 23″; the Uralian, 77° 31′ 20″; the Philippine, 77° 23′ 27″. Kupffer made this angle 78° 1′; Brooke & Miller, 77° 55′; Haidinger obtained from one crystal 77° 10′; and by deductions from other measurements of 4 crystals 77° 29′—77° 57′.

Dauber gives figures of fifty-four different crystals. The Brazilian have usually the plane $4\text{-}i$, and an extreme variety of this form is shown in f. 532. One form from the Philippines is the fundamental octahedron 1, −1; another I, −1, or I, −1, $i\text{-}\grave{2}$, in slender prisms; while others approach the Uralian in form.

Comp.—$\dot{\mathrm{P}}\mathrm{b}\,\dddot{\mathrm{C}}\mathrm{r}$=Oxyd of lead 68·9, chromic acid 31·1=100. Analyses: 1, Pfaff (Schw. J., xviii. 72); 2, Berzelius (ib., xxii. 54):

1.	$\dddot{\mathrm{C}}\mathrm{r}$ 31·735	$\dot{\mathrm{P}}\mathrm{b}$ 67·912=99·647	Pfaff.
2.	31·50	68·50=100	Berzelius.

Vauquelin discovered the metal *chromium* in this mineral in 1794 (l. c., 1794, 1798, and J. d M., ii. 737).

Pyr., etc.—In the closed tube decrepitates, blackens, but recovers its original color on cooling B.B. fuses at 1·5, and on charcoal is reduced to metallic lead with deflagration, leaving a residue of chrome-oxyd, and giving a lead coating. With salt of phosphorus gives an emerald-green bead in both flames. Fused with bisulphate of potash in the platinum spoon forms a dark violet mass, which on solidifying becomes reddish, and when cold greenish-white, thus differing from vanadinite, which on similar treatment gives a yellow mass (Plattner).

Obs.—First found at Beresof in Siberia, in crystals in quartz veins, or intersecting gneiss or granite; also occurs at Mursinsk and near Nischne Tagilsk in the Ural, in narrow veins, traversing decomposed gneiss, and associated with gold, pyrite, galenite, quartz, and vauquelinite; in Brazil, at Congonhas do Campo, in fine crystals in decomposed granite; at Retzbanya in Hungary, at the mine of St. Anthony; Moldawa in Hungary; on Luzon, one of the Philippines, whence crystals were received by the author in 1842, from El Senor Roxas of Manila, and understood to be from the northern peninsula of Luzon; according to Dr. Hochstetter, at the mines of Labo, in the Province of North Camarines, on the southeastern peninsula of Luzon (Dauber).

This species was first noticed by Lehman (l. c.). The name *Crocoite* is from κρόκος, *saffron*. Berthier, in 1832, gave the word the bad form *Crocoise*, which von Kobell altered (to make it conformable to ordinary mineralogical nomenclature) in 1838, to *Crocoisite*, and Breithaupt, in 1841, to *Crocoite* (Krokoit), and v. Kobell also to this last mentioned form in his later works. Hausmann's *Callochrome* has the priority; but as the name is a poorer one, not mineralogical in form, and the species was not one instituted by Hausmann, we allow *Crocoite* to stand.

643. PHŒNICOCHROITE. Melanochroit *Hermann*, Pogg., xxviii. 162, 1833. Phœnikochroit *Glocker*, Grundr., 612, 1839. Subsesquichromate of Lead *Thom.* Phœnicit *Haid.*, Handb., 504, 1845.

Orthorhombic? Crystals usually tabular, and reticularly interwoven. Cleavage in one direction perfect. Also massive.

H.=3–3·5. G.=5·75. Lustre resinous or adamantine, glimmering. Color between cochineal- and hyacinth-red; becomes lemon-yellow on exposure. Streak brick-red. Subtranslucent—opaque.

Comp.—$\dot{\mathrm{P}}\mathrm{b}^3\,\dddot{\mathrm{C}}\mathrm{r}^2$=Chromic acid 23·1, protoxyd of lead 76·9=100. **Analysis**: Hermann (Pogg., xxviii. 162):

Chromic acid 23·31	Protoxyd of lead 76·69=100.

The same result was obtained by G. Rose (Jahrb. Min. 1839, 575).

Pyr., etc.—B.B. on charcoal fuses readily to a dark mass, which is crystalline when cold. In R.F. on charcoal gives a coating of oxyd of lead, with globules of lead and a residue of chrome-oxyd. Gives the reaction of chrome with fluxes.

Obs.—Occurs in limestone at Beresof in the Ural, with crocoite, vauquelinite, pyromorphite, and galenite.

Named *Melanochroite* by Hermann, from μέλας, *black*, and χρόα, *color*. But, as the color is red, and not black, and the name is therefore false to the species, Glocker changed it to *Phœnicochroite*, from φοίνικος, *deep red*, and χρόα; and in this he is followed by Hausmann. The abbreviated form *phœnicite* is bad, because it is too much like the name of another mineral, *phenacite*.

644. VAUQUELINITE. Vauqueline *Berz.*, Afh., vi. 100, 1818. Vauquelinite *Berz.*, N. Syst. Min. Paris, 202, 1819. Chromate of Lead and Copper.

Monoclinic. Crystals usually minute, irregularly aggregated. Twins: annexed figure; composition-face a plane on the acute solid angle: $O \wedge O$ (of the two individuals) =134° 30′; $O \wedge i\text{-}\grave{i}=149°$ nearly. Also reniform or botryoidal, and granular; amorphous.

533

H.=2·5–3. G.=5·5–5·78. Lustre adamantine to resinous, often faint. Color green to brown, apple-green, siskin-green, olive-green, ochre-brown, liver-brown; sometimes nearly black. Streak greenish or brownish. Faintly translucent—opaque. Fracture uneven. Rather brittle.

Comp.—$\dot{\mathrm{C}}\mathrm{u}^3\,\bar{\mathrm{C}}\mathrm{r}^2+2\,\dot{\mathrm{P}}\mathrm{b}^3\,\bar{\mathrm{C}}\mathrm{r}^2=(\dot{\mathrm{C}}\mathrm{u},\dot{\mathrm{P}}\mathrm{b})^3\,\bar{\mathrm{C}}\mathrm{r}^2$=Oxyd of lead 61·4, oxyd of copper 10·9, chromic acid 27·7=100. Analysis by Berzelius (l. c.):

$\bar{\mathrm{C}}\mathrm{r}$ 28·33 $\dot{\mathrm{P}}\mathrm{b}$ 60·87 $\dot{\mathrm{C}}\mathrm{u}$ 10·80=100.

Pyr., etc.—B.B. on charcoal slightly intumesces and fuses to a gray submetallic globule, yielding at the same time small globules of metal. With borax or salt of phosphorus affords a green transparent glass in the outer flame, which in the inner after cooling is red to black, according to the amount of mineral in the assay; the red color is more distinct with tin. Partly soluble in nitric acid.

Obs.—Occurs with crocoite at Beresof in Siberia, generally in mammillated or amorphous masses, or thin crusts; also at Pont Gibaud in the Puy de Dome; and with the crocoite of Brazil.

At the lead mine near Sing Sing it has been found by Dr. Torrey in green and brownish-green mammillary concretions, and also nearly pulverulent; and at the Pequa lead mine in Lancaster Co., Pa., in minute crystals and radiated aggregations on quartz and galenite, of siskin- to apple-green color, with cerussite.

Named after Vauquelin, the discoverer of the metal chromium, and also the first one to notice the crystals of this species (J. d. M., No. VI. i. 760).

John describes a greenish or brownish *chromo-phosphate of lead and copper* (chromphosphorkupferbleispath) from Beresof, Siberia, as occurring in small crystalline concretions, having the surface covered with capillary prisms; H.=2—3; opaque to subtranslucent; fracture uneven; powder dull greenish. Analysis afforded (Jahrb. Min. 1845, 67) $\dot{\mathrm{P}}\mathrm{b}\,\bar{\mathrm{C}}\mathrm{r}$ 45·0, $\dot{\mathrm{P}}\mathrm{b}$ 19·0, $\dot{\mathrm{C}}\mathrm{u}$ 11·20, $\bar{\mathrm{P}}$ 4·10, $\bar{\mathrm{C}}\mathrm{r}$ 7·50, manganese *tr.*, $\dot{\mathrm{H}}$ 1·78, impurities 11·42. To a large extent soluble in nitric or muriatic acid. It is probably only an impure vauquelinite.

645. **Jossaite** *Breith.* (B. H. Ztg., xvii. 54, 1858). From Beresof, occurring in small orange-yellow crystals with vauquelinite. Described as orthorhombic, with $I \wedge I$=110°—118°, and traces of prismatic cleavage; the lustre between vitreous and waxy; streak dull yellowish-white; H.=3·0; G.=5·2. According to Plattner, it gives the reactions of chromic acid and oxyds of lead and zinc.

646. PETTKOITE. Pettkoit *A. Paulinyi*, Jahrb. Min. 1867, 457.

Isometric. Common form the cube; also f. 6, and f. 6 with planes of the dodecahedron. Cleavage: none distinct.

H.=2·5. Lustre bright. Color pure black. Streak dirty greenish. Fracture uneven. Taste sweetish.

Comp.—An acid sulphate of iron; O. ratio for $\dot{\mathrm{F}}\mathrm{e} : \ddot{\bar{\mathrm{F}}}\mathrm{e} : \bar{\mathrm{S}} : \dot{\mathrm{H}}$=1·5 : 13·5 : 27 : 1·5. Allowing for some hydrated oxyd of iron as impurity (about 10·5 p. c., as 1·51 of water would require 9·1 of $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ for limonite), the formula may be $(\dot{\mathrm{F}}\mathrm{e}^3, \ddot{\bar{\mathrm{F}}}\mathrm{e})\,\bar{\mathrm{S}}^2$, with $\dot{\mathrm{F}}\mathrm{e}^3 : \ddot{\bar{\mathrm{F}}}\mathrm{e}$=1 : 7. Analysis: A. Paulinyi (l. c.):

$\bar{\mathrm{S}}$ 45·32 $\ddot{\bar{\mathrm{F}}}\mathrm{e}$ 44·92 $\dot{\mathrm{F}}\mathrm{e}$ 6·66 $\dot{\mathrm{H}}$ 1·51=98·41.

Pyr., etc.—In a closed tube yields water. B B. on charcoal yields a magnetic mass; with soda gives the sulphuric acid reaction. Wholly soluble in hot water, with a deposit of a flocculent reddish-brown precipitate. Soluble in dilute muriatic acid.

Obs.—From Kremnitz, in a breccia, along with iron-vitriol (melanterite), in crystals from the size of peas to millets, and in grains. Named after Bergrath v. Pettko.

647. ALUMIAN. *Breith.*, B. H. Ztg., xvii. 53, 1858.

Rhombohedral? Crystals microscopic. Cleavage, traces. Also massive.

H.=2—3. G.=2·702—2·781. Lustre of small crystals vitreous; of masses weak. Color white. Subtranslucent.

Comp.—$\bar{\text{A}}\text{l}\,\dddot{\text{S}}^3$ (?)=Sulphuric acid 60·9, alumina 39·1. According to Utendörffer's determinations (l. c.), contains 37–38 p. c. of alumina, with sulphuric acid, and no water.

Pyr., etc.—B.B. unaltered; only hygroscopic water given off, but at a high temperature sulphuric acid, which may be detected by litmus paper. With cobalt solution a fine blue.

Obs.—From mines in the Sierra Almagrera, southern Spain.

HYDROUS SULPHATES.

ARRANGEMENT OF THE SPECIES.

I. Oxygen ratio for bases and acid 1 : 3; the species coming under the general formula $\dot{\text{R}}\,\dddot{\text{S}}+n$ aq, $\bar{\text{R}}\,\dddot{\text{S}}^3+n$ aq, or $(\dot{\text{R}}^3, \bar{\text{R}})\dddot{\text{S}}^3+n$ aq.

A. *Sulphates of Elements in the Protoxyd state.*

1. Contain ammonium. Orthorhombic, with $I \wedge I$=100°—108°.

650.	Mascagnite	$\text{N H}^4\text{O}\,\dddot{\text{S}}+\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\text{N H}_4)_2+\text{aq}$
651.	Boussingaultite	(?) $\text{N H}^4\text{O}, \dot{\text{Mg}}, \dddot{\text{S}}, \dot{\text{H}}$	
652.	Lecontite	$(\dot{\text{Na}}, \dot{\text{K}}, \text{N H}^4\text{O})\dddot{\text{S}}+2\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\text{Na}, \text{K}, \text{N H}_4)_2+2\,\text{aq}$

2. Contain sodium, without magnesium. calcium, or iron.

653.	Mirabilite	$\dot{\text{Na}}\,\dddot{\text{S}}+10\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|\text{Na}_2+10\,\text{aq}$

3. Contain calcium or magnesium, with or without the alkaline metals; less than 4 of $\dot{\text{H}}$ to 1 of $\dddot{\text{S}}$. Monoclinic or orthorhombic.

654.	Gypsum	$\dot{\text{Ca}}\,\dddot{\text{S}}+2\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|\Theta\text{a}+2\,\text{aq}$
655.	Kieserite	$\dot{\text{Mg}}\,\dddot{\text{S}}+\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|\bar{\text{M}}\text{g}+\text{aq}$
656.	Polyhalite	$(\frac{2}{4}\dot{\text{Ca}}+\frac{1}{4}\dot{\text{Mg}}+\frac{1}{4}\dot{\text{K}})\dddot{\text{S}}+\frac{1}{2}\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\frac{1}{4}\text{K}_2+\frac{2}{4}\Theta\text{a}+\frac{1}{4}\bar{\text{M}}\text{g})+\frac{1}{2}\text{aq}$
657.	Mamanite	$(\frac{3}{6}\dot{\text{Ca}}+\frac{2}{6}\dot{\text{Mg}}+\frac{1}{6}\dot{\text{K}})\dddot{\text{S}}+\frac{1}{3}\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\frac{1}{6}\text{K}_2+\frac{3}{6}\Theta\text{a}+\frac{2}{6}\bar{\text{M}}\text{g})+\frac{1}{3}\text{aq}$
658.	Picromerite	$(\frac{1}{2}\dot{\text{Mg}}+\frac{1}{2}\dot{\text{K}})\dddot{\text{S}}+3\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\frac{1}{2}\text{K}_2+\frac{1}{2}\bar{\text{M}}\text{g})+3\,\text{aq}$
659.	Blœdite	$(\frac{1}{2}\dot{\text{Mg}}+\frac{1}{2}\dot{\text{Na}})\dddot{\text{S}}+2\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\frac{1}{2}\text{Na}_2+\frac{1}{2}\bar{\text{M}}\text{g})+2\,\text{aq}$

4. Bases and water as in section 3. Crystals tetragonal.

660.	Lœweite	$(\frac{1}{2}\dot{\text{Mg}}+\frac{1}{2}\dot{\text{Na}})\dddot{\text{S}}+1\frac{1}{2}\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\frac{1}{2}\text{Na}_2+\frac{1}{2}\bar{\text{M}}\text{g})+1\frac{1}{2}\text{aq}$

5. EPSOMITE GROUP. Contain magnesium, iron, manganese, etc.; 4–7 of $\dot{\text{H}}$ to 1 of $\dddot{\text{S}}$ Orthorhombic; $I \wedge I$=90°—93°.

661.	Epsomite	$\dot{\text{Mg}}\,\dddot{\text{S}}+7\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|\bar{\text{M}}\text{g}+7\,\text{aq}$
662.	Taurisoite	$\dot{\text{Fe}}\,\dddot{\text{S}}+7\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|\bar{\text{F}}\text{e}+7\,\text{aq}$
663.	Fauserite	$(\frac{1}{2}\dot{\text{Mn}}+\frac{1}{2}\dot{\text{Mg}})\dddot{\text{S}}+5\,\dot{\text{H}}$	$\text{S}\,\Theta_2\|\Theta_2\|(\frac{1}{2}\bar{\text{M}}\text{g}+\frac{1}{2}\bar{\text{M}}\text{n})+5\,\text{aq}$

6. COPPERAS GROUP. Basic elements and water as in section 5. Monoclinic, with $I \wedge I =$ 82°–92°; or triclinic.

664.	**Melanterite**	$\dot{Fe}\,\dddot{S}+7\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|Fe}+7$ aq
665.	**Pisanite**	$(\dot{Fe}, \dot{Cu})\,\dddot{S}+7\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(Fe, \Theta u)}+7$ aq
666.	**Goslarite**	$\dot{Zn}\,\dddot{S}+7\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|Zn}+7$ aq
667.	**Bieberite**	$\dot{Co}\,\dddot{S}+7\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|\Theta o}+7$ aq
668.	**Morenosite**	$\dot{Ni}\,\dddot{S}+7\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|Ni}+7$ aq
669.	**Chalcanthite**	$\dot{Cu}\,\dddot{S}+5\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|\Theta u}+5$ aq

7. CYANOCHROITE GROUP. Contain copper and potassium.

670.	**Cyanochroite**	$(\frac{1}{2}\dot{K}+\frac{1}{2}\dot{Cu})\,\dddot{S}+3\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{2}K_2+\tfrac{1}{2}\Theta u)}+3$ aq

B. *Sulphates of Elements in the Sesquioxyd state, or Sesquioxyd and Protoxyd.*

8. ALUNOGEN GROUP. O. ratio for $\dddot{\bar{R}}$, $\dddot{S}$, $\dot{H}=1:3:9$ to $1:3:18$.

671.	**Alunogen**	$\dddot{\bar{Al}}\,\dddot{S}^3+18\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|\beta Al}+6$ aq
672.	**Coquimbite**	$\dddot{\bar{Fe}}\,\dddot{S}^3+9\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|\beta Fe}+3$ aq

9. ALUM GROUP. O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{S}$, $\dot{H}=1:3:12:24$; for bases, acid, and water, $1:3:6$. Crystals isometric.

673.	**Tschermigite**	$(\frac{1}{4}(\mathrm{N\,H^4\,O})^2+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+18\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}(N\,H_4)_2+\tfrac{3}{4}\beta Al)}+6$ aq
674.	**Kalinite**	$(\frac{1}{4}\dot{K}^3+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+18\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}K_2+\tfrac{3}{4}\beta Al)}+6$ aq

10. VOLTAITE GROUP. O. ratio for $\dot{R}$, $\dddot{\bar{R}}$ not $1:3$; for bases, acid, and water, $1:3:4$. Crystals isometric.

675.	**Voltaite**	$(\dot{Fe}^3, \dddot{\bar{Fe}})\,\dddot{S}^3+12\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(Fe, \beta Fe)}+4$ aq
676.	**Blakeite**		

11. HALOTRICHITE GROUP. O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{S}$, $\dot{H}=1:3:12:22$; for bases, acid, and water, $1:3:5\frac{1}{2}$. Crystallization orthorhombic or monoclinic, usually fine fibrous or acicular.

This group is related in ratio to the Alum group, it differing only in 22 instead of 24 of water. But the real difference may be much greater, and this is rather to be inferred from the unusual ratio for the water. If 2 of the 22 of water are basic, the O. ratio for bases and acid is then $1:2$, and for bases, acid, and water, $1:2:3\frac{1}{2}$. The formulas of the species below, based on this ratio, would have the general form $(\frac{1}{2}(\dot{R}, \dot{H})^3+\frac{1}{2}\dddot{\bar{Al}})\,\dddot{S}^3+10\,\dot{H}$; or, in the now system, $\mathrm{S\,\Theta|\Theta_2|\,(\tfrac{1}{2}(H_2, R)+\tfrac{1}{2}\beta\,Al)}+3\frac{1}{2}$ aq.

677.	**Mendozite**	$(\frac{1}{4}\dot{Na}^3+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+16\frac{1}{2}\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}Na_2+\tfrac{3}{4}\beta Al)}+5\frac{1}{2}$ aq
678	**Pickeringite**	$(\frac{1}{4}\dot{Mg}^3+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+16\frac{1}{2}\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}Mg+\tfrac{3}{4}\beta Al)}+5\frac{1}{2}$ aq
679.	**Apjohnite**	$(\frac{1}{4}\dot{Mn}^3+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+16\frac{1}{2}\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}Mn+\tfrac{3}{4}\beta Al)}+5\frac{1}{2}$ aq
680.	**Bosjemannite**	$(\frac{1}{4}(\dot{Mn}^3, \dot{Mg})+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+16\frac{1}{2}\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}(Mn, Mg)+\tfrac{3}{4}\beta Al)}+5\frac{1}{2}$ aq
681.	**Halotrichite**	$(\frac{1}{4}\dot{Fe}^3+\frac{3}{4}\dddot{\bar{Al}})\,\dddot{S}^3+16\frac{1}{2}\,\dot{H}$	$\mathrm{S\,\Theta_2|\Theta_2|(\tfrac{1}{4}Fe+\tfrac{3}{4}\beta Al)}+5\frac{1}{2}$ aq

12. RŒMERITE GROUP.

682. **Rœmerite**	$(\frac{1}{4}\dot{\mathrm{F}}\mathrm{e}^3+\frac{3}{4}\not{\mathrm{F}}\mathrm{e})\bar{\mathrm{S}}^3+12\dot{\mathrm{H}}$	$\mathrm{S}\,\Theta_2\vert\Theta_2\vert(\frac{1}{4}\mathrm{Fe}+\frac{3}{4}\beta\mathrm{Fe})+3\,\mathrm{aq}$

II. Sulphates, with oxygen ratio of bases and acid 1 to less than 3; not containing Copper or Uranium.

The copper and uranium hydrous sulphates are of uncertain formulas, and are therefore placed by themselves. There is also much uncertainty with regard to the true formulas of the species here included, on account of the doubtful relations of the water.

1. O. ratio for bases (no water included) and acid 2 : 5, 2 : 3, 3 : 5

683. **Copiapite**	$\not{\mathrm{F}}\mathrm{e}^2\bar{\mathrm{S}}^5+12\dot{\mathrm{H}}$ (or $18\dot{\mathrm{H}}$)	$\mathrm{S}_5\,\Theta_3\vert\Theta_{12}\vert\beta\mathrm{Fe}_4+12\,\mathrm{aq}$
684. **Raimondite**	$\not{\mathrm{F}}\mathrm{e}^2\bar{\mathrm{S}}^3+7\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{S}\,\Theta\vert\Theta_4\vert\beta\mathrm{Fe}_2+2\frac{1}{2}\,\mathrm{aq}$
685. **Fibroferrite**	$\not{\mathrm{F}}\mathrm{e}^3\bar{\mathrm{S}}^6+27\dot{\mathrm{H}}$	$\mathrm{S}_6\,\Theta_6\vert\Theta_{12}\vert\beta\mathrm{Fe}_6+27\,\mathrm{aq}$
686. **Apatelite**	$\not{\mathrm{F}}\mathrm{e}^3\bar{\mathrm{S}}^6+2\dot{\mathrm{H}}$	$\mathrm{S}_6\,\Theta_6\vert\Theta_{12}\vert\beta\mathrm{Fe}_6+2\,\mathrm{aq}$

2. O. ratio for bases (no water included) and acid 1 : 2.

687. **Botryogen**	$(\frac{1}{4}\dot{\mathrm{F}}\mathrm{e}^3+\frac{3}{4}\not{\mathrm{F}}\mathrm{e})\bar{\mathrm{S}}^2+9\dot{\mathrm{H}}$	$\mathrm{S}_2\,\Theta_2\vert\Theta_6\vert(\mathrm{Fe},\beta\mathrm{Fe})_2+9\,\mathrm{aq}$

3. O. ratio of bases (water excluded) and acid 1 : 1½ to 1 : 1; but if some water be made basic, 1 : 1 for all, as in the formulas below.

688. **Aluminite**	$\not{\mathrm{A}}\mathrm{l}\,\bar{\mathrm{S}}+9\dot{\mathrm{H}}$	$\mathrm{S}\vert\Theta_3\vert\beta\mathrm{Al}_2+9\,\mathrm{aq}$
689. **Alunite**	$(\frac{1}{3}(\dot{\mathrm{K}},\dot{\mathrm{H}})^3+\frac{2}{3}\not{\mathrm{A}}\mathrm{l})\bar{\mathrm{S}}+\dot{\mathrm{H}}$	$\mathrm{S}\vert\Theta_3\vert(\frac{1}{3}(\mathrm{K}_2,\mathrm{H}_2)+\frac{2}{3}\beta\mathrm{Al})_2+\mathrm{aq}$
690. **Löwigite**	$(\frac{1}{3}(\dot{\mathrm{K}},\dot{\mathrm{H}})^3+\frac{2}{3}\not{\mathrm{A}}\mathrm{l})\bar{\mathrm{S}}+1\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{S}\vert\Theta_3\vert(\frac{1}{3}(\mathrm{K}_2,\mathrm{H}_2)+\frac{2}{3}\beta\mathrm{Al})_2+1\frac{1}{2}\,\mathrm{aq}$
691. **Jarosite**	$(\frac{1}{3}(\dot{\mathrm{K}},\dot{\mathrm{N}}\mathrm{a},\dot{\mathrm{H}})^3+\frac{2}{3}\not{\mathrm{F}}\mathrm{e})\bar{\mathrm{S}}+1\frac{1}{2}\dot{\mathrm{H}}$	$\mathrm{S}\vert\Theta_3\vert(\frac{1}{3}(\mathrm{R}_2,\mathrm{H}_2)+\frac{2}{3}\beta\mathrm{Al})_2+1\frac{1}{2}\,\mathrm{aq}$
692. **Carphosiderite**	$(\frac{1}{3}\dot{\mathrm{H}}^3+\frac{2}{3}\not{\mathrm{F}}\mathrm{e})\bar{\mathrm{S}}+2\dot{\mathrm{H}}$	$\mathrm{S}\vert\Theta_3\vert(\frac{1}{3}\mathrm{H}_2+\frac{2}{3}\beta\mathrm{Fe})_2+2\,\mathrm{aq}$

The species *Copiapite*, *Raimondite*, *Fibroferrite*, *Botryogen*, may be here included, if part of the water is basic.

4. O. ratio of bases and acid 1 to less than 1.

693. **Paraluminite**	$\not{\mathrm{A}}\mathrm{l}^2\bar{\mathrm{S}}+15\dot{\mathrm{H}}$	$\beta\mathrm{Al}_4\,\Theta_3\vert\Theta_3\vert\mathrm{S}+15\,\mathrm{aq}$
694. **Pissophanite**	? $(\not{\mathrm{A}}\mathrm{l},\not{\mathrm{F}}\mathrm{e})^2\bar{\mathrm{S}}+15\dot{\mathrm{H}}$	$\beta(\mathrm{Al},\mathrm{Fe})_4\,\Theta_3\vert\Theta_3\vert\mathrm{S}+15\,\mathrm{aq}$
695. **Felsobanyite**	$\not{\mathrm{A}}\mathrm{l}^2\bar{\mathrm{S}}+10\dot{\mathrm{H}}$	$\beta\mathrm{Al}_4\,\Theta_3\vert\Theta_3\vert\mathrm{S}+10\,\mathrm{aq}$

Appendix.—SELENATES?

712. KERSTENITE

650. MASCAGNITE. *Mascagni*, Dei Lagoni, etc., in Siena, 1779. Sel ammoniac vitriolique, Sel ammoniac secret de Glauber (fr. Solfatara near Naples), *Sage*, Min., i. 62, 1777. Ammoniaque sulfatée *Fr.* Sulphate of Ammonia. Maskagnin *Karst.*, Tab., 40, 75, 1800.

Orthorhombic. $I \wedge I=107°\ 40'$, $O \wedge 1\text{-}\bar{i}=122°\ 56'$, $a : b : c=1{\cdot}5437 : 1 : 1{\cdot}3680$. Cleavage: $i\text{-}\breve{i}$ perfect; O imperfect.

$O \wedge \frac{1}{2}\text{-}\bar{i}=150°\ 34'$ | $\frac{1}{2}\text{-}\breve{i} \wedge \frac{1}{2}\text{-}\breve{i}$, bas., $=58°\ 52'$ | $i\text{-}\breve{2} \wedge i\text{-}\breve{2}=111°\ 15'$
$O \wedge \frac{3}{2}\text{-}\breve{i}=125\ 34$ | $\frac{3}{2}\text{-}\breve{i} \wedge \frac{3}{2}\text{-}\breve{i}=118\ 52$ | $\frac{1}{2} \wedge \frac{1}{2}$, over I, $=87\ 26$

Usually in mealy crusts and stalactitic forms.

H.=2–2·5. G.=1·72–1·73. Lustre when crystallized, vitreous. Color yellowish-gray, lemon-yellow. Translucent. Taste pungent and bitter.

Comp.—$NH^4O\dddot{S}+\dot{H}$=Sulphuric acid 53·3, ammonia 34·7, water 12·0=100.

Pyr., etc.—In the closed tube yields water and is sublimed; with lime gives off ammonia vapors. Dissolves readily in water, and gives with baryta salts a precipitate insoluble in acids.

Obs.—Occurs about volcanoes, in the fissures of the lava, as at Etna, Vesuvius, and the Lipari Isles, and is also one of the products of the combustion of mineral coal.

Named after Professor Mascagni.

651. BOUSSINGAULTITE. *E. Bechi*, C. R., lviii. 583, 1864.

A sulphate of ammonia with part of this alkali replaced by magnesia. Crystals resemble those of mascagnite, but isomorphism with that species has not yet been established.

Occurs about the boric acid fumaroles of Tuscany.

652. LECONTITE. *W. J. Taylor*, Am. J. Sci., II. xxvi. 273, 1858.

Orthorhombic. In prismatic crystals, long or short. $I \wedge I$ (calc. from

$i\text{-}\bar{2} \wedge i\text{-}\bar{2})=103^\circ\,12'$, $O \wedge 1\text{-}\bar{i}=117^\circ\,7'$; $I \wedge i\text{-}\bar{2}=160^\circ$, $i\text{-}\bar{2} \wedge i\text{-}\bar{2}=115^\circ$, $\frac{1}{2}\bar{i} \wedge \frac{1}{2}\text{-}\bar{i}=127^\circ\,30'-128^\circ$, or over $i\text{-}\bar{i}$, $52^\circ-52^\circ\,30'$, Dana.

H.=2—2·5. Lustre vitreous. Colorless, when pure, and transparent. Taste saline and rather bitter. Permanent in the air.

Comp.—$\dot{R}\bar{S}+2\dot{H}$ or $((\dot{N}a, \dot{K}), NH^4O)\bar{S}+2\dot{H}$. Analysis by Taylor (l. c.):

$\bar{S}$	NH^4O	$\dot{N}a$	$\dot{K}$	$\dot{H}$
44·97	12·94	17·56	2 67	19·45

With 2·30 organic residue, 0·11 inorganic id., and $\dot{P}$ *tracé*.

Pyr., etc.—Only partially sublimed in the closed tube, but otherwise reacts like mascagnite.

Obs.—From the cave of Las Piedras, near Comayagua, Central America, imbedded in a black mass made up of the excrement of bats. The crystals often have a coating of organic matter. The cave is worked for the nitre, which the earth of the floor near its mouth affords by lixiviation.

Named after Dr. John L. Le Conte.

An artificial salt of similar general formula, but having ammonia and potash as its bases, is well known (Gmelin's Ch., iii. 119).

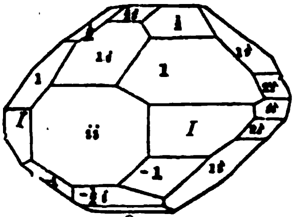
584



Monoclinic. $C=72^\circ\,15'$, $I \wedge I=86^\circ\,31$, $O \wedge 1\text{-}\grave{i}=130^\circ\,19'$; $a:b:c=1{\cdot}1089:1:0{\cdot}8962$. Observed planes as in the annexed figure.

$O \wedge i\text{-}i=107^\circ\,45'$	$1 \wedge 1$, front, $=93^\circ\,12'$
$O \wedge \frac{1}{2}\text{-}i=147\ 34$	$-1 \wedge -1$, front, $=110\ 42$
$O \wedge 1\text{-}i=122\ 5$	$i\text{-}i \wedge 1\text{-}i=130\ 10$
$O \wedge -\frac{1}{2}\text{-}i=155\ 41$	$i\text{-}i \wedge \frac{1}{2}\text{-}i=104\ 41$
$O \wedge 2\text{-}\grave{i}=113\ 0$	

Cleavage: $i\text{-}i$ perfect. Usually in efflorescent crusts.

H.=1·5—2. G.=1·481. Lustre vitreous. Color white. Transparent—opaque. Taste cool, then feebly saline and bitter.

Comp.—$\dot{N}a\bar{S}+10\dot{H}$=Soda 19·3, sulphuric acid 24·8, water 55·9=100.

Analyses: 1, Rivot (Ann. d. M., V. vi. 558); 2, Moissenet (ib., xvii. 16); 3, How (Ed. N. Phil J., II. vi. 54):

	$\bar{S}$	$\dot{N}a$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$	
1. Guipuzcoa, Spain	24·8	19·5	0·5	0·3	54·5	Rivot.
2. St. Rambert, France	26·0	20·0	0·7	H Cl *tr.*	53·3	Moissenet.
3. Windsor, N. Scotia	44·54		—	—	55·46	How.

Pyr., etc.—In the closed tube much water; gives an intense yellow to the flame. Very soluble in water; the solution gives with baryta salts the reaction for sulphuric acid. Falls to powder on exposure to the air, and becomes anhydrous.

Obs.—Occurs at Ischl and Hallstadt in Austria; also in Hungary, Switzerland, Italy; at Guipuzcoa in Spain, etc.; abundantly at the hot springs at Carlsbad; at Kailua, on Hawaii, Sandwich Islands, abundant in a cavern, and forming from the action of volcanic heat and gases on salt water. Effloresces with other salts on the limestone below the Genesee Falls, Rochester N. Y.; at Windsor, Nova Scotia; also near the Sweetwater River, Rocky Mountains.

The artificial salt was discovered by Glauber, a German chemist, about the middle of the seventeenth century, while he was operating with sulphuric acid and common salt; and the name *sal mirabile* was his own expression of surprise at its formation.

Taking the plane 1-*i* as 2-*i*, the axes are nearly those of pyroxene, becoming $a : b : c = 0{\cdot}55445 : 1 : 0{\cdot}8962$.

The so-called *Reussin* is impure glauber salt, as pronounced by Reuss in 1791, after his early study of it. It occurred as a deposit of crystals and efflorescent crusts in or about the mineral springs of Saidschitz and Sedlitz, and according to Reuss was most abundant near the end of the spring. The crystals (some of which were ¼ to 2 in. long) had the form of stout 6-sided prisms, with two sides smaller than the others, terminating in two rhomboidal planes—the form of glauber salt. It is stated to have become a white powder on the expulsion by heat of the crystallization-water. The analysis was made first on a *solution* of the salt, and afterward on the effloresced salt, which contained as a result of efflorescence (the usual result) no water; and hence the amount of water was not ascertained. Crystals reproduced from the solution lost more than half their weight when heated to redness; corresponding with the fact that both glauber salt and epsomite contain more than 50 p. c. of water. The analysis afforded Reuss $\dot{\mathrm{N}}\mathrm{a}\,\dddot{\mathrm{S}}$ 66·04, $\dot{\mathrm{M}}\mathrm{g}\,\dddot{\mathrm{S}}$ 31·55, Mg Cl 2·19, $\dot{\mathrm{C}}\mathrm{a}\,\dddot{\mathrm{S}}$ 0·42; which, adding the water and excluding the Mg Cl, corresponds to 68·0 of glauber salt, 31·7 of epsomite, and 0·3 of gypsum = 100.

EXANTHALOSE *Beud.* (Tr., ii. 475, 1832) is a white efflorescence, such as results from the exposure to the air of glauber salt. Beudant obtained the composition $\dot{\mathrm{N}}\mathrm{a}\,\dddot{\mathrm{S}} + 2\,\dot{\mathrm{H}}$ from the analyses

1. Vesuvius	$\dddot{\mathrm{S}}$ 44·8	$\dot{\mathrm{N}}\mathrm{a}$ 35·0	$\dot{\mathrm{H}}$ 20·2
2. Hildesheim	42·5	38·4	18·8

The Vesuvian mineral was from the lavas of 1813, according to Beudant. It was named from ἐξανθίω, *to effloresce*, and ἅλς, *salt*.

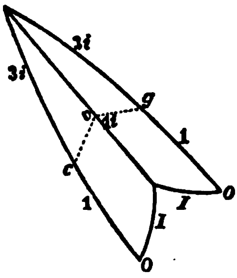
O ∧ 2=98 46		

Cleavage: (1) *i*-ì, or clinodiagonal, eminent, affording easily smooth polished folia; (2) *I*, imperfect, fibrous, and often apparent in internal rifts or linings, making with *O* (or the edge 2-ì / 2-ì) the angles 66° 14′ and 113° 46′, corresponding to the obliquity of the fundamental prism; (3) *O*, or the base, imperfect, but affording a nearly smooth surface. Twins: 1. Composition-face *O* (f. 538), occurring (A) in the form represented in f. 535, having then the reëntering angle 104° 32′, and the cross-lining of the second cleavage (or that parallel to *I*) in the directions *cv*, *vg*, meeting in the angle *cvg*=132° 28′, or twice 66° 14′; also occurring (B) in a form made up of planes 2-ì and *I* (instead of 2-ì, 1), and having a reëntering angle of 132° 28′, at the opposite end of the crystal, the cleavage lines being parallel to the sides of the reëntering angle. 2. Composition-face 1-*i*, or edge 1 / 1 (=*l* / *l*), reëntering angle made between edge *I* / *I* (=*n* / *n*) of each part,=123°, or double the supplement of 1-*i* on edge *I* / *I* (which equals 61° 30′); twins of this second kind often lenticular; also like f. 539 (compare with f. 537) the reëntering edges made of the planes *I* (*n*), and the outer convex edges either of planes 1 (*l*) and 3-*i* (*e*) blended together, and meeting at extremity in an angle of 25½°, or of planes 1 and 2-*i*, and having the angle at extremity 55°; the interior cleavage lines parallel to *I*, having the directions *cv*, *vg*, meeting the axis at 61½°, or one another in the angle 123°. Simple crystals often with warped as well as curved surfaces. Also foliated massive; lamellar-stellate; often granular massive; and sometimes nearly impalpable.

539



H.=1·5—2. G.=2·314—2·328, when pure crystals. Lustre of *i*-ì pearly and shining, other faces subvitreous. Massive varieties often glistening, sometimes dull earthy. Color usually white; sometimes gray, flesh red, honey-yellow, ochre-yellow, blue; impure varieties often black, brown, red, or reddish-brown. Streak white. Transparent—opaque.

Var.—1. *Crystallized*, or *Selenite;* either in distinct crystals, or in broad folia, the folia sometimes a yard across and transparent throughout.

(*b*) An *arenaceous* variety occurs in Sussex, N. Brunswick, the crystals containing much sand, which is often regularly arranged within them (C. C. Marsh).

2. *Fibrous;* coarse or fine. (*a*) *Satin spar*, when fine-fibrous a variety which has the pearly opalescence of moonstone; (*b*) *plumose*, when radiately arranged.

3. *Massive; Alabaster*, a fine-grained variety, either white or delicately shaded; *scaly-granular; earthy* or *rock-gypsum*, a dull-colored rock, often impure with clay or carbonate of lime, and sometimes with anhydrite. The *Montmartre* gypsum contains carbonate of lime, and Delame-

therie called it *Montmartrite.* A variety from Bovenden, near Göttingen, contains anhydrite (Jahrb. Min. 1856, 664).

Comp.—$\dot{C}a\,\dddot{S}+2\,\dot{H}$=Sulphuric acid 46·5, lime 32·6, water 20 9=100. Analyses: 1, Bucholz (Gehlen's J., v. 159); 2, v. Rose (Karst. Min. Tab., 53, 1808); 3, De la Trobe (Ramm. 4th Suppl., 89); 4, 5, Jüngst (ZS. nat. Ver. Halle, viii. 482); 6, 7, W. Hampe (B. H. Ztg., xx. 267):

The siliceous variety from Albay, Luzon (Philippine islands), was of volcanic origin.

The gypsum of East River, Pictou, Nova Scotia, according to Prof. W. R. Johnson, and that of Southern Virginia, according to Prof. W. B. Rogers (Am. J. Sci., II. v. 113, 1848), contain 1 atom of water to 2 of sulphate of lime ($2\,\dot{C}a\,\dddot{S}+\dot{H}$), the former affording $\dddot{S}$ 54·7, lime 39·4, $\dot{H}$ 5·90. The passage of anhydrite into gypsum is exemplified on a large scale in many places, as at the Canaria valley and at Box in Switzerland (Blum. Pseud., p. 24; Am. J. Sci., xlviii. 69), and the compound here described may have been formed in the course of the transition; or, more probably, it is a *mixture* of gypsum and anhydrite. This compound is formed artificially only at a high temperature, or above 120° C. The incrustations in steam-boilers on the ocean consist largely of it, as shown by J. F. W. Johnston, and later by R. W. Johnson, who gave for the composition of one (Am. J. Sci., II. v. 112, 1848), having G.=2·69, and a fibrous structure, Sulphuric acid 54·25, lime 39·67, water 6·07, equivalent to 2 of $\dot{C}a\,\dddot{S}$ to 1 of $\dot{H}$. T. L. Phipson found in one (Inventor's Institute, Dec., 1867) Sulphate of lime 65·0, magnesia 19·0, water 13·5, $\dddot{F}e$, $\dddot{A}l$ 0·85, Na Cl 0·70, sand 0·45=99·50; corresponding to 1 of $\dot{C}a\,\dddot{S}+\dot{H}$ and 1 of $\dot{M}g\,\dot{H}$ (brucite).

Pyr., etc.—In the closed tube gives off water and becomes opaque. Fuses at 2·5—3, coloring the flame reddish-yellow. For other reactions, see ANHYDRITE, p. 621. Ignited at a temperature not exceeding 260° C., it again combines with water when moistened, and becomes firmly solid. Soluble in muriatic acid, and also in 400 to 500 parts of water.

Obs.—Gypsum often forms extensive beds in connection with various stratified rocks, especially limestones, and marlytes or clay beds. It occurs occasionally in crystalline rocks. It is also a product of volcanoes, occurring about fumaroles, or where sulphur gases are escaping, being formed from the sulphuric acid generated, and the lime afforded by the decomposing lavas—lime being contained in augite and labradorite. It is also produced by the decomposition of pyrite when lime is present; and often about sulphur springs where sulphuretted hydrogen is emitted, this gas changing, through reaction with vegetable matter, into sulphuric acid. Gypsum is also deposited on the evaporation of sea-water and brines, in which it exists in solution. Crystals may be seen to form on evaporating a drop of sea-water in the field of a microscope.

Fine specimens are found in the salt mines of Bex in Switzerland; at Hall in the Tyrol; in the sulphur mines of Sicily; in the gypsum formation near Oçana in Spain; in the clay of Shotover Hill, near Oxford; and large lenticular crystals have been met with at Montmartre, near Paris. A noted locality of alabaster occurs at Castelino, 35 m. from Leghorn, whence it is taken to Florence for the manufacture of vases, figures, etc.

This species occurs in extensive beds in several of the United States, and more particularly N. York, Ohio, Illinois, Virginia, Tennessee, and Arkansas, and is usually associated with salt springs. Also in Nova Scotia, Peru, etc.

Handsome selenite and snowy gypsum occur in *N. York*, near Lockport (occasionally f. 532) in limestone along with pearl spar and anhydrite: also near Camillus, Onondaga Co.; occasionally crystals are met with in the vicinity of Manlius. In *Maryland*, large grouped crystals on the St. Mary's, in clay; also near the mouth of the Patuxent. In *Virginia*, large beds of gypsum with rock salt, in Washington Co., 18 m. from Abingdon; also near Lynchburg. In *Ohio*, large transparent crystals have been found at Poland and Canfield, Trumbull Co. In *Tenn.*, selenite and alabaster in Davidson Co. In *Kentucky*, in Mammoth Cave, it has the forms of rosettes, or flowers, vines, and shrubbery. Abundant also W. of the Mississippi in many places, and in California.

In *N. Scotia*, in Sussex, King's Co., on Capt. McCready's farm, large single and grouped crystals, which mostly contain much symmetrically disseminated sand.

Plaster of Paris (or gypsum which has been heated and ground up) is used for making moulds, taking casts of statues, medals, etc.; for producing a hard finish on walls; also in the manufacture of artificial marble, as the scagliola tables of Leghorn, and in the glazing of porcelain.

The fibrous variety, when cut *en cabochon* and polished, resembles cat's-eye.

Gypsum is related in form to heulandite, a fact brought out in the view above taken of its crystallization (Am. J. Sci., II. xvii. 85). To the table of observed planes the lettering of Brooke and Miller for the planes is added. Plane *I* of f. 537 would be situated on f. 536, between 2-ì and 3-ì below, or the back 2-ì and 3-ì above. Kenngott obtained from an English crystal 2-ì ∧ 2-ì = 111° 14′ (Ber. Ak. Wien, xi.).

Recent articles on cryst., B. & M. Min., 536; Quenstedt, Min., 1855, 1863; Dufrénoy, Min., 1856; Hessenberg, Min. Not., No. ii. iv. There seems to be good reason for accepting as the true fundamental form that above adopted, since the planes of the fundamental prism *I*, and *O*, correspond in this case to directions of cleavage. Most authors make 2-ì the prism *I*, and 2-ĭ (of rare occurrence) the plane *O*. The symbols, on this basis, with the lettering of Miller, are as follows, following the above order (Hessenberg, Min. Not., No. iv.): *i*-ĭ (*a*); *i*-ì (*b*), 1-ĭ (*t*), 1 (*n*), 2-2̀ (*x*), 3-3̀ (*s*); *I* (*m*, or *f* of Neumann), *i*-$\grave{\frac{3}{2}}$, *i*-$\grave{\frac{7}{4}}$, *i*-2̀ (*h*), *i*-$\grave{\frac{7}{3}}$, *i*-$\grave{\frac{5}{2}}$, *i*-3̀ (*k*), *i*-$\grave{\frac{7}{2}}$, *i*-4̀, *i*-$\grave{\frac{9}{2}}$; −1-ĭ (*d*), *O* (*q* of Quenstedt), $\frac{1}{2}$-ĭ (*e*), $\frac{2}{3}$-ĭ (*β* of Hessenberg); −1 (*l*), 1-ì (*v*), 1-3̀ (*u*), $\frac{1}{2}$ (*w*); −3-3̀ (*y*, or *k* of Neumann); $\frac{6}{5}$-$\grave{2}$ (*δ* of Hessenberg).

Named from γύψος, the Greek for the mineral, but more especially for the *calcined* mineral. The derivation ordinarily suggested, from γῆ, *earth*, and ἑψέω, *to cook*, corresponds with this, the most common use of the word among the Greeks. Theophrastus, after mentioning localities, speaks of the making of gypsum by burning the proper stones (among which *alabaster* is included); of making plaster or cement from it by "powdering it, pouring on water, and stirring it with wooden instruments, there being too much heat for the hand;" of the necessity of preparing it "immediately before the use of it, because it soon dries and becomes hard;" of its value for whitening the walls of houses, and of its being an excellent material for making images and ornaments.

The word γύψος in Plato and Herodotus has been sometimes translated *chalk*, but not so in the latest and best Lexicon—the recent edition of Stephanus. The sentences in Herodotus containing it, and the verb γυψόω derived from it meaning *to cover or whiten with gypsum*, are most intelligible if calcined gypsum, or preparations from it, are understood.

Powdered chalk is not likely to have been used for a whitewash; and a wash is implied instead of dry chalking. Moreover, true chalk was probably unknown to the Greeks, it being a production of more western countries; and, according to Pliny, even the Romans included under their term *Creta* (Latin for *chalk*) principally clays, and prominently the "Cimolian earth" (Cimolite, p. 457), true chalk being what Pliny calls "the inferior kind." Theophrastus speaks of a *Tymphæan gypsum* (so called by the people of Tymphæa) which was a fuller's earth of some kind. The word γύψος is, therefore, much more likely to have been applied at times to white clays than to true chalk. The ancients were acquainted with lime from the burning of limestone, and could not have called this γύψος. Plato's expression, Τὴν δὲ ὅση λευκὴ γύψου ἢ χιόνος λευκοτέραν, "Whiter than gypsum or snow," is not improved by supposing it chalk; for there is nothing whiter than calcined gypsum, or the ceilings or ornaments made from it.

Selenites (=moon-stone) of Dioscorides, which he says was also called *aphroselenon* (moon-froth), "because it was found at night while the moon was on the increase," was probably crystallized gypsum or modern selenite. His description λευκός, διαυγής, κοῦφος (=*white, transparent, light*), is good as far as it goes; and the uses of the stone which he mentions also agree better with this view than with that of its being either the modern *moonstone* or *cat's-eye*, to which it has been referred. The name is from σελήνη, *moon*, and alludes probably to the peculiar moon-like white reflections. Some aggregated crystallized masses might well have suggested the name *aphroselenon*. It is doubtful what Pliny had in view under the name *selenitis* (xxxvii. 67); it is probable, from his brevity on the subject, that he did not know the mineral.

Lapis specularis (Specular-stone) of Pliny was mostly crystallized gypsum (the rest being *mica*), he speaks of it (xxxvi. 59) as affording by burning the best of gypsum.

Ἀλαβαστρίτης (or alabaster-stone, meaning the stone out of which ointment vases of the kind called *alabastra* were made) was with Theophrastus and Pliny mainly if not wholly stalagmite, which is now often called *oriental alabaster* (see under Calcite); and Thebes in Egypt was a famous locality. Such vases were made of other materials, and it is possible that gypsum-alabaster was one; for when polished it often resembles some clouded stalagmites. This opinion is favored—though not placed beyond question—by the statement in Theophrastus, which Pliny reiterates,* that the gypsum-stone is "very similar to," "not unlike" (meaning in the rough state, of course) *alabastrites*, which resemblance is not obvious if stalagmite is the only alabastrites. The *alabastritis* of Pliny, from Syria, said to be white spotted with various tints, may be of this kind, as Syria was noted for its gypsum-stone, according to Theophrastus and Pliny.

---

* It is not clear that Pliny is here independent authority. He appears to be citing from Theophrastus in the most of what he says about gypsum; and in one or two cases he cites blunderingly. He says, for instance, that plaster after hardening may by pounding be powdered [for use again]; whereas Theophrastus states more correctly that "*by burning* it may again and again be made fit for use."

'Αλάβαστρον (alabastron) occurs as the name of alabaster-stone in the writings of the historian Herodianus about two centuries after Christ, but without description. The *alabastrum* of Pliny, something white and froth-like, called also, as he says, *stimmi*, *stibi*, and *larbasis*, and coming from silver mines, cannot be alabaster. There is here probably some mistake on the part of Pliny.

Burnt gypsum is called Plaster-of-Paris, because the Montmartre gypsum quarries, near Paris, are, and have long been, famous for affording it.

Alt.—Gypsum occurs altered to calcite, malachite, quartz.

655. KIESERITE. Kieserit *Reichardt*, Salzbergwerk Stassfurt, 1860; B. H. Ztg., xx. 39, 1861. Martinsite *Kenngott*, Ueb., 1856–57, 22; *Ramm.*, Pogg., xcviii. 262, 1856 (not Martinsite *Karsten*, 1845).

Orthorhombic. Massive; fine granular or compact.

H.=2·5. G.=2·517, Bischof. Color white, grayish-white, to yellowish. Translucent to opaque. Friable to firm. Little soluble.

Comp.—$\dot{\mathrm{Mg}}\dddot{\mathrm{S}}+\dot{\mathrm{H}}$=Sulphuric acid 58·0, magnesia 29·0, water 13·0=100. **Analyses:** 1, Rammelsberg (Pogg., xcviii. 262); 2–4, Siewert & Leopold (Jahresb., 1860, 788); 5, Reichardt (Jahrb. Min. 1866, 343):

	$\dddot{\mathrm{S}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$
1. Stassfurt	57·7	26·8	[15·5]=100 Ramm.
2. "	58·98	28·51	13·47=100·96 Siewert.
3. "	58·90	28·61	[12·49]=100 Siewert.
4. "	57·78	28·78	14·13=100·69 Leopold.
5. "	54·16	28·11	14·30, Cl 2·18, insol. 0·39=99·14 Reichardt.

Reichardt in his earliest analyses obtained (l. c.) $\dddot{\mathrm{S}}$ 43·05, $\dot{\mathrm{Mg}}$ 21·66, $\dot{\mathrm{H}}$ 34·56, which corresponds to $\dot{\mathrm{Mg}}\dddot{\mathrm{S}}+3\dot{\mathrm{H}}$. Anal. 2, 3, are of an opalescent, translucent, and friable variety, and 4 of a darker yellow, opaque, and much harder kind.

Pyr., etc.—In the closed tube yields water. B.B. fuses easily, and with soda on charcoal gives the sulphuric acid reaction. But little altered at 100° C. Dissolves in nitric acid, leaving a small residue of impurities. Soluble slowly in water, but completely, 100 of water taking up 40·9 parts; a residue is deposited of microscopic crystals of anhydrite, or of stassfurtite.

Obs.—From the salt mine of Stassfurt, often mixed with carnallite and gypsum. F. Bischof divides the Stassfurt salt beds vertically (Ann. Ch. Phys., IV. v. 305, and B. H. Ztg., xxiv. 1865) into 4 regions, corresponding, he observes, to the natural order of origin from an evaporating saline: 1, or lower, the *anhydrite* region; 2, the *polyhalite*; 3, the *kieserite*; and 4, the *carnallite*. The kieserite is in beds, 9 to 12 in. thick, alternating with common salt. The whole deposit is about 190 feet thick, and has the following as its mean percentage composition: Common salt 65, kieserite 17, carnallite 13, chlorid of magnesium (hydrated) 3, anhydrite 2=100.

Named after Mr. Kieser, President of the Academy of Jena. For the *martinsite* of Karsten, see under HALITE, p. 112.

656. POLYHALITE. Polyhalites *Strom.*, Comment. Soc. R. Götting., iv. 139. Polyhalit *Strom.*, Unters., i. 444, 1821.

Orthorhombic? Clinohedral? Descl. A prism of 115°, with acute edges truncated. Usually in compact fibrous masses.

H.=2·5–3. G.=2·7689. Lustre resinous or slightly pearly. Streak red. Color flesh- or brick-red, sometimes yellowish. Translucent—opaque. Taste bitter and astringent, but very weak.

Comp.—$\dot{\mathrm{R}}\dddot{\mathrm{S}}+\frac{1}{2}\dot{\mathrm{H}}$, in which $\dot{\mathrm{R}}=\dot{\mathrm{K}}$, $\dot{\mathrm{Mg}}$, $\dot{\mathrm{C}}\mathrm{a}$ in the ratio 1 : 1 : 2=Sulphate of lime 45·2, sul. magnesia 19·9, sul. potash 28·9, water 6·0=100. **Analyses:** 1, Stromeyer (Unters., i. 144); 2, Rammelsberg (Pogg., lxviii. 512); 3, Dexter (Pogg., xciii. 1); 4, Behnke (ib.); 5, C. 11. "	43·44	20·56	——	26·22	——	——	7 47, Mg Cl 0·58=98·27 Reichardt.

From analysis 9, 6·23 p. c. of clay have been removed, and part of the 7·40 p. c. of water belongs with it.

Berthier's analyses of the Vic polyhalite (Ann. d. M., x. 260) were incorrect. The loc. Gmunden (anal. 5) should be either Ischl or Aussee, according to Rammelsberg, who says the mineral does not occur near Gmunden (Min. Ch., 283, 1862). Joy says in a letter to the author dated Oct., 1865, that it was brought to G. Rose's laboratory so labelled.

Pyr., etc.—In the closed tube gives water. B.B. fuses at 1·5, colors the flame yellow. On charcoal fuses to a reddish globule, which in R.F. becomes white, and on cooling has a saline hepatic taste; with soda like glauberite. With fluor does not give a clear bead. Partially soluble in water, leaving a residue of sulphate of lime, which dissolves in a large amount of water.

Obs.—Occurs at the mines of Ischl, Ebensee, Aussee, Hallstatt, and Hallein in Austria, with common salt, gypsum, and anhydrite; at Berchtesgaden in Bavaria; at Vic in Lorraine.

The name Polyhalite is derived from πολύς, *many*, and ἅλς, *salt*, in allusion to the number of salts in the constitution of the mineral.

For remarks on the position of the polyhalite at Stassfurt see **KIESERITE**, p. 641.

657. **MAMANITE** *A. Goebel* (Bull Ac. St. Petersb., ix. 16, 1865). Like polyhalite in aspect and characters, but has the $\dot{K}$, $\dot{Mg}$, $\dot{Ca}$ in the ratio 1 : 2 : 3. Color white; lustre silky; structure foliated fibrous. In nodules as large as the fist, at the salt mine of Maman in Persia, with carnallite, and also investing or intersecting nodules of carnallite.

658. PICROMERITE. Picromeride *Scacchi*, Mem. Incend. Vesuv. 1855, 191. Pikromerit *Ramm.*, Min. Ch., 281, 1860. Kainit *Zincken*, B. H. Ztg., xxiv. 79, 1865. Schönit *E. Reichardt*, Jahrb. Min. 1865, 602, 1866, 340.

Monoclinic. $C=75^\circ\ 12'$, $I \wedge I=109^\circ\ 50'$, $O \wedge 1\text{-}i=154^\circ\ 39'$, $O \wedge 2\text{-}i=116^\circ\ 41'$. In crystals and crystalline crusts.
H.=2·5. Color white.

Comp. $\dot{K}\dddot{S}+\dot{Mg}\dddot{S}+6\dot{H}$, or $(\frac{1}{2}\dot{K}+\frac{1}{2}\dot{Mg})\dddot{S}+3\dot{H}$=Sulphuric acid 39·8, magnesia 9·9, potash 23·5, water 26·8=100. Analyses: H. Reichardt (l. c.):

	$\dddot{S}$	$\dot{Mg}$	$\dot{K}$	$\dot{H}$	Cl
1. Stassfurt	38·52	11·56	22·82	[26·29]	0·81=100.
2. "	39·74	10·40	23·28	26·87	0·28=100·57.

Reichardt's analyses were made on his *schönite*, a salt obtained by him by separating the chlorid of magnesium in what is called kainite by means of alcohol.

Pyr., etc.—Loses 11 p. c. water at 100° C., and all the rest by heating to 133° C., Reichardt. According to Graham, the artificial salt loses its water wholly at 132°.

Obs.—Found at Vesuvius among the salts produced at the eruption in 1855, in crystals along with crystals of cyanochroite, an isomorphous species in which copper replaces the magnesia. Also occurs at the Stassfurt salt mine, along with kieserite and carnallite. It is often mixed, at Stassfurt, with chlorids and other salts. Alcohol dissolves out chlorid of magnesium.

Kainite of Zincken, from the same locality at Stassfurt, is nothing but the impure picromerite just alluded to, as shown by Reichardt. It has been analyzed by Graf (B. H. Ztg., xxiv. 288); E. and H. Reichardt, Hosseus, and Theile (Jahrb. Min. 1866, 337); Philip (ZS. G., xvii. 649); and the chlorine in the results varies from 14·5 to 36·7 p. c. Nearly all the chlorine is removed as chlorid of magnesium on treating the mineral with alcohol. Forms granular masses which vary in color from colorless to grayish, yellowish, and reddish, and has G.=2·131—2·147, but varying to 2·184. It sometimes contains also common salt. Named *picromerite* in allusion to the magnesia present; and Kainite (properly *Cænite*) from *καινός*, *recent*.

659. BLŒDITE. Blœdit *John*, Unters., 1811. Astrakanit *G. Rose*, Reis. Ural, ii. 270, 271, 1842.

In imperfect crystals. Also massive.
Color whitish, orange, reddish. Translucent. Very soluble.

Var.—The original *blœdite* from Ischl, analysed by John, was massive, somewhat fibrous, flesh-red to brick-red in color, and splintery in fracture. The *astrakanite*, from near Astrakan, was in whitish crystals.

Comp.—$\dot{R}\dddot{S}+2\dot{H}$, with $\dot{R}=\frac{1}{2}\dot{M}g+\frac{1}{2}\dot{N}a$=Sulphate of soda 42·6, sulphate of magnesia 35·9, water 21·5=100. Analyses: 1, John (l. c.); 2, v. Hauer (Jahrb. G. Reichs., 605, 1856); 3, Göbel (Rose's Reis. Ural, l. c.); 4, Hayes (Proc. N. H. Bost., v. 391):

	$\dot{N}a\dddot{S}$	$\dot{M}g\dddot{S}$	Na Cl	Mg Cl	$\dot{H}$
1. Ischl, *rdh.*	33·34	36·66	0·33	—	22·00, $\dot{M}n\dddot{S}$ 0·33, $\bar{F}e\dddot{S}$ 0·34=93·00 John.
2. " *orange*	41·02	36·36	0·50	—	21·50=99·38 Hauer.
3. Astrakan	41·73	35·81	—	0·34	21·95=99·83[a] Göbel.
4. Mendoza	45·74	33·31	1·16	—	19·60, sand, etc. 0·19=100 Hayes.
5. "	45·82	33·19	1·79	—	18·84, sand, etc. 0·36=100 Hayes.

[a] 1·75 clay and sand removed.

Another sample afforded Hayes $\dot{N}a\dddot{S}$ 48·00, $\dot{M}g\dddot{S}$ 34·20, Na Cl 1·21, $\dot{H}$ 16·42, $\ddot{S}i$, etc. 0·17=100. Dried at 90° F. the water was reduced to 15·20 p. c. The less amount of water in Hayes's analyses than in the others may have been due to the degree of drying.

Pyr., etc.—Heated loses water rapidly; at a red heat fuses quietly to a transparent globule, which is white on cooling. Somewhat deliquescent in a moderately moist atmosphere.

Obs.—From the salt mines of Ischl; the salt lakes near Astrakan, east of the mouth of the Volga (anal. 3); the soil of the country near Mendoza, between San Luis de la Punta and the foot of the Andes, especially east of San Juan, occurring in imperfect crystals at the junction of two layers of common salt, one to two feet below the surface.

Named after the chemist and mineralogist Blöde.

660. LŒWEITE. Löweit *Haid.*, Abh. Ges. Wiss. Prag, V. iv. 1846; *Haid.*, Ber. Fr. Nat., ii. 266, 1847.

Tetragonal. Massive. Cleavage octahedrons have approximately the angles 111° 44′ and 105° 2′, giving for the vertical axis the value 1·304. Cleavage: basal, distinct; *I*, imperfect; 1, or the octahedral, in traces.

H.=2·5—3·0. G.=2·376. Lustre vitreous. Color yellowish-white to honey-yellow, also reddish. Fracture conchoidal, with the aspect somewhat of fire-opal. Taste weak. Optically uniaxial; refraction positive, for the ordinary ray 1·491, extraord. 1·494.

Comp.—$\dot{R}\dddot{S}+1\frac{1}{2}\dot{H}$, with $\dot{R}=\frac{1}{2}\dot{M}g+\frac{1}{2}\dot{N}a$=Sulphate of soda 46·3, sulphate of magnesia 39·1, water 14·7. Analyses: 1, Karafiat (l. c.); 2, v. Hauer (Jahrb. G. Reichs., 1856, 605):

	$\dddot{S}$	$\dot{M}g$	$\dot{N}a$	$\dot{H}$
1.	52·35	12·78	18·97	14·45, $\bar{F}e$, $\bar{A}l$ 0·66=99·21 Karafiat.
2.	52·53	14·31	18·58	14·80=100·22 Hauer.

Obs.—In pure crystalline masses an inch thick, involved with foliated anhydrite, at the Ischl salt mine, Austria.

661. EPSOMITE. Epsom Salt. Sal nativum catharticum *A. Hermann*, De Sale nativo cathartico in fodinis Hungariæ recens invento, Posonii, 1721. Sal neutrum acidulare, Sal

Anglicanum, *Wall.*, Min., 184, 1747. Id., Sel d'Epsom *Fr. Trl.* Wall., i. 339, 1753. Halotrichum *Scopoli*, De Hydrarg. Idriense Tent., Venet, 1761 (Klap. Beitr., iii. 104), Princip. 5. Fitou, France	34·37	17·31	—	—	48·32=100 Bouis.
6. " "	34·07	16·20	—	—	47·20, $\dot{\mathrm{C}}$a 2·10=99·57 Dufrénoy.

Pyr., etc.—Liquifies in its water of crystallization. Gives much water in the closed tube at a high temperature; the water is acid. B.B. on charcoal fuses at first, and finally yields an infusible alkaline mass, which, with cobalt solution, gives a pink color on ignition. Very soluble in water, and has a very bitter taste.

Obs.—Common in mineral waters, and as a delicate fibrous or capillary efflorescence on rocks in the galleries of mines, and elsewhere. In the former state it exists at Epsom, England, and at Sedlitz and Saidschutz in Bohemia. At Idria in Carniola it occurs in silky fibres, and is hence called *hairsalt* by the workmen. Also obtained at the gypsum quarries of Montmartre, near Paris; in Fitou, Dept. of the Aude, France; in Aragon and Catalonia in Spain; in the Cordillera of St. Juan in Chili; and in a grotto in Southern Africa, where it forms a layer 1½ in. thick. Also found at Vesuvius, at the eruptions of 1850 and 1855.

The floors of the limestone caves of Ky., Tenn., and Ind., are in many instances covered with epsomite, in minute crystals, mingled with the earth. In the Mammoth Cave, Ky., it adheres to the roof in loose masses like snowballs. At the Alum Cave, in Sevier, Tenn., on the headwaters of the West Fork of Little Pigeon River, masses of nearly pure epsomite, almost a cubic foot in volume, have been obtained (Safford's Rep., 119). It effloresces from the calcareous sandstone, 10 m. from Cocymans, on the east face of the Helderberg, N. Y. Said to occur also over the California plains, east of San Diego (Am. J. Sci., II. vi. 389). Also effloresces from a pyritiferous serpentine in Marmora, Canada West; and on dolomites of the Clinton formation (Silurian) in sheltered places between Niagara Falls and Lake Huron, as at Dundas, where layers occur 1 in. thick.

Sulphate of magnesia is dimorphous. According to Haidinger and Mitscherlich, the above described form is produced when crystallization takes place below 15° C. (60° F.), but a monoclinic form between 25° C. and 30° C.

662. TAURISCITE. Tauriszit *G. H. O. Volger*, Jahrb. Min. 1855, 152.

Orthorhombic. Angles those of epsomite. Occurring planes: I, $i\text{-}\breve{\imath}$, $i\text{-}\bar{\imath}$, $i\text{-}\breve{2}$; $1\text{-}\breve{\imath}$, $1\text{-}\bar{\imath}$; 1, $2\text{-}\breve{2}$, $2\text{-}\bar{2}$. Crystals acicular.

Lustre and other physical characters those of copperas.

Comp.—Stated to be that of copperas.

Obs.—From Windgälle in the Canton Uri (Pagus Tauriscorum of the Romans), Switzerland, associated with copperas and alum. The crystal is a rhombic prism with pyramidal terminations

662A. TECTICITE *Breith.* (Graulit *Glocker*, Syn., 1847). A clove-brown mineral, easily soluble in water and attracting moisture readily, occurring in small pyramidal and acicular crystals supposed to be orthorhombic, and also massive. Probably a hydrous sulphate of sesquioxyd of iron; but composition not ascertained. H.=1·5–2.

From Graul, near Schwarzenberg, in Saxony, and Bräunsdorf in the Erzgebirge. Named from τηκτικός, in allusion to the deliquescence; but changed to *graulite* by Glocker, because the Greek signifies liquifying *actively*, and not *passively* as in deliquescence.

663. FAUSERITE. Fauserit *Breith.*, B. H. Ztg., xxiv. 301, 1865.

Orthorhombic. $I \wedge I=91° 18'$. Cleavage: *i-ĭ* distinct; *I* in traces or none; *O* rather distinct. Crystals grouped in stalactitic forms.

H.=2–2½. G.=1·888. Lustre vitreous. Color reddish- and yellowish-white to colorless. Translucent to transparent. Taste astringent, bitter.

Comp.—$\dot{M}g\dddot{S}+2\dot{M}n\dddot{S}+15\dot{H}=(\frac{1}{3}\dot{M}g+\frac{2}{3}\dot{M}n)\dddot{S}+5\dot{H}$=Sulphuric acid 34·7, protox. manganese 20·5, magnesia 5·8, water 39·0=100. Analyses: 1, 2, Mollnár (l. c.):

$\dddot{S}$	$\dot{M}n$	$\dot{M}g$	$\dot{H}$	
34·49	19·61	5·15	42·66,	$\bar{A}l$, $\bar{F}e$ *trace*
33·78	20·05	5·63	40·54.	

Obs.—From Herrengrund in Hungary. Named after Mr. Fauser.

COPPERAS GROUP.

The species here included are the ordinary vitriols. They are identical in general formula with the species of the Epsomite group, and are regarded as the same compound essentially under oblique crystallization. The copper sulphate diverges from the others in crystallization, and contains but 5 of water; but species containing copper in many other groups exhibit a like divergence from the rest in crystalline form.

SYNONYMY BEFORE 1750. Χάλκανθον, Χαλκῖτις, Μελαντηρία, Σῶρυ, Μίσυ, *Dioscor.*, v. 114–118. [*Chalcanthum* (from χαλκός, *brass*, and ἄνθος, *flower*) is vitriol of any kind; Spain is given as a locality; *Chalcitis*, a disintegrating pyrites, iron or copper, impregnated with the same, as a result of its alteration; *Melanteria* (fr. μέλαν, *ink*), a salt-like chalcanthus, or earth containing it; *Soru*, a black earth or stone impregnated with some vitriol; *Misu*, a yellowish vitriolic stone, perhaps partly copiapite, and partly yellow ochre impregnated with vitriol of some kind.*]

Atramentum sutorium=Chalcanthum, Chalcites, Sory, Misy, *Plin.*, xxxiv. 29–32; evidently in part from Dioscorides. [The description of *Chalcanthum* gives prominence to *blue* vitriol, while its use as shoemaker's ink (which Atr. sutorium signifies) implies the presence of *green* (or iron) vitriol, the material still used for blackening leather; *Chalcites* and *sory* are the same as above; *Misy* is yellow and pulverulent, like the mineral now called copiapite.]

Atramentum sutorium=Melanteria=Chalcanthum, Chalcites, Sory, Misy, *Agric.*, Foss., 212–214, 1546; Kupferwasser *id.*, Interpr., 463, 1546. [The first three of these names are synonyms for any vitriol or all; and include (as partly also in Dioscorides) capillary or wool-like, plumose, stalactitic, and salt-like kinds, besides *Lapis atramenti*; Agricola mentions the varieties *Atramentum sutorium candidum* (=λευκοιον *Gr.*), which is white or zinc vitriol; *A. s. viride*, which is green vitriol; *A. s. cæruleum*, which is blue vitriol; *Sory*, a gray or blackish stone, often nodular (gleba rotundæ), impregnated with any vitriol; *Misy*, a yellow efflorescent or mealy vitriol (*Copiapite*). Goslar in the Harz is the principal locality cited by Agricola. *Chalcites* is said to be between sory and misy in texture, and *rubra et æris colore*; perhaps a red ochre (a frequent result of the alteration of pyrites) containing copperas and some unaltered pyrites.

---

* In interpreting these ancient names it has to be borne in mind that there are three sources of obscurity, besides that of imperfect description:

1. That the earthy or stony mass containing the essential ingrediant comes into the description.
2. That Pyrites (including pyrite, marcasite and pyrrhotine) is brassy enough to be confounded with chalcopyrite. the ore of copper or brass (χαλκός); and, in fact, Dioscorides says that pyrites yields χαλκός, although in the next line asserting that it strikes fire with a steel, a characteristic distinguishing it from copper pyrites. Moreover, Agricola describes all the vitriols under his *Atramenta sutoria*, and makes *Kupferwasser* of the Germans (meaning *copper water*) a common synonym for them; as has been true of *Copperas* in English and *Couperose* in French.
3. That iron and copper pyrites often occur together, and the vitriolic results of their alteration are consequently variously mixed in nature.

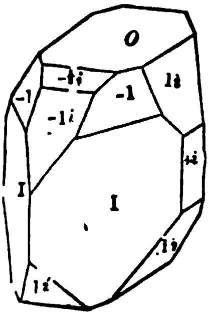
Atramentum viride, a quibusdam *Vitreolum* vocatur, *Albertus Magnus*, De Min., Libr. v., c. 5, 1270. Vitriolum *Agric.*, ib., 218. [So named from *vitrum*, *glass*, in allusion to the glassy appearance of the crystals of vitriols; Agricola speaks in connection with his explanation of the word, of "A. candidum translucidum instar Crystalli."]

Atramentum *Gesner*, Foss., 13, 1565; divided into A. album durum Goslarianum [or Zinc vitriol], A. viride [or Iron vitriol], A. cœruleum Cyprium pulcherrimum [or Blue vitriol], etc. Melanteria, Sory, Misy, *Gesner*, ib., 15, 16.

Vitriolum *Wallerius*, Min., 155, 1747, and *Cronstedt*, Min., 113, 1758; a genus including the species V. Cupri (=V. Cypri, V. Veneris); 2, V. viride (=V. ferri, V. martis); 3, V. album, vel Zinci (from Goslar); besides 4, V. mixtum (a mere mixture); 5, 6, Terra vitriolica and Lapis atramentarius (earth or stone impregnated with vitriol of some kind), and including Lapis atramentarius flavus, or *Misy*.

664. MELANTERITE. Μελαντηρία, Χαλκάνθον, etc., *Dioscor.* Chalcanthum, Atramentum sutorium, etc., *Plin.* Melanteria, Atramentum sutorium viride, *Agric.* Vitriolum pt. *Albertus Magnus.* Atramentum viride *Gesner.* Vitriolum viride, V. ferri, V. martis, *Wallerius.* Green Vitriol. Copperas. Sulphate of Iron. Fer sulfaté *Fr.* Melantérie *Beud.*, Tr., ii. 482, 1832.

540



Monoclinic. $C=75° 40'$; $I \wedge I=82° 21'$, $O \wedge 1\text{-}i=123° 44'$; $a:b:c=1{\cdot}310:1:0{\cdot}8474$.

$O \wedge i\text{-}i=104° 20'$ $O \wedge -1\text{-}i=136° 18$
$O \wedge I=80\ 37$ $O \wedge 1\text{-}i=123\ 44$
$O \wedge -\frac{1}{3}\text{-}i=159\ 6$ $-1 \wedge -1=101\ 32$

Cleavage: *O* perfect, *I* less so. Often in capillary, fibrous, stalactitic, and concretionary forms. Generally massive and pulverulent.

H.=2. G.=1·832. Lustre vitreous. Color, various shades of green, passing into white; becoming yellowish on exposure. Streak uncolored. Subtransparent—translucent. Taste sweetish, astringent, and metallic. Fracture conchoidal. Brittle.

Comp.—$\dot{\mathrm{Fe}}\,\dddot{\mathrm{S}}+7\dot{\mathrm{H}}$=Sulphuric acid 28·8, protoxyd of iron 25·9, water 45·3=100.

Pyr., etc.—In the closed tube yields water, and after a time sulphurous and sulphuric acids. On charcoal turns at first brown, then red, and finally black, becoming magnetic. With the fluxes reacts for iron. Soluble in twice its weight of water, and the solution is blackened by a tincture of nut galls. Exposed to the air becomes covered with a yellow powder, which is the sulphate of the sesquioxyd of iron.

Obs.—This salt usually proceeds from the decomposition of pyrite or marcasite, which readily afford it, if occasionally moistened while exposed to the atmosphere. Occurs near Goslar in the Harz; Bodenmais in Bavaria; Fahlun, Sweden; at Hurlet, near Paisley; and in many mines in Europe and on the other continents. Usually accompanies pyrite in the U. States, occurring as an efflorescence; at Copperas Mt., a few miles E. of Bainbridge, Ohio, it is associated with alum and pyrite. It is employed in dyeing and tanning, and in the manufacture of ink and Prussian blue

665. PISANITE. *F. Pisani*, C. R., xlviii. 807. Pisanit *Kenng.*, Ueb. 1859, 10, 1860.

In concretionary and stalactitic forms.

Lustre vitreous. Color bright blue. Becomes ochreous externally.

Comp.—$(\dot{\mathrm{Fe}},\dot{\mathrm{Cu}})\dddot{\mathrm{S}}+7\dot{\mathrm{H}}$; or a copperas with three-fifths of the iron replaced by copper Analysis by Pisani (l. c.):

$\dddot{\mathrm{S}}$ 29·90 $\dot{\mathrm{Fe}}$ 10·98 $\dot{\mathrm{Cu}}$ 15·56 $\dot{\mathrm{H}}$ 43·56

Pyr., etc.—B.B. gives with the fluxes reactions for copper. Otherwise like melanterite.

Obs.—Occurs with chalcopyrite at a copper mine in the interior of Turkey. The interior of the mineral has sometimes druses of minute crystals.

666. GOSLARITE. Atramentum sutorium, candidum, potissimum reperitur Goselariæ, translucidum, crystalli instar, *Agric.*, Foss., 213, 1546. A. album fossile durum Goslarianum *Gesner*, Foss., 13, 1565. Vitriolum Zinci album nativum, Galizensten, Hvit Viktril, *Wall.*, 157, 1747. Zinc Vitriol, White Vitriol, White Copperas, Sulphate of Zinc. Zinc sulfatée, Couperose blanche, *Fr.* Gallizinite *Beud.*, Tr., 446, 1824. Goslarit *Haid.*, Handb., 490, 1847.

Orthorhombic. $I \wedge I = 90° \; 42'$; $O \wedge 1\text{-}\bar{i} = 150° \; 10'$; $a : b : c = 0{\cdot}5735 : 1 : 1{\cdot}0123$. Observed planes: I, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, $i\text{-}\breve{2}$, $1\text{-}\bar{i}$, $1\text{-}\breve{i}$, 1, $2\text{-}\breve{2}$. $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, top, $=120° \; 20'$, $1\text{-}\breve{i} \wedge 1\text{-}\breve{i}$, top, $=120° \; 3'$, $O \wedge 1 = 140° \; 57'$, $1 \wedge 1$, mac., $=127° \; 27'$, $1 \wedge 1$, brach., $=126° \; 45'$. Cleavage: $i\text{-}\breve{i}$ perfect.

H.=2–2·5. G.=2·036; 1·9–2·1; 1·953, artificial crystals, Schill. Lustre vitreous. Color white, reddish, bluish. Transparent—translucent. Brittle. Taste astringent, metallic, and nauseous.

Comp.—$\dot{\mathrm{Zn}}\dddot{\mathrm{S}}+7\dot{\mathrm{H}}$=Sulphuric acid 27·9, oxyd of zinc 28·2, water 43·9=100. Beudant obtained for a specimen from Schemnitz (Tr., ii. 481) $\dddot{\mathrm{S}}$ 29·8, $\dot{\mathrm{Zn}}$ 28·5, $\dot{\mathrm{Mn}}$ 0·7, $\dot{\mathrm{Fe}}$ 0·4, $\dot{\mathrm{H}}$ 40·8=100·2, which corresponds to 6 $\dot{\mathrm{H}}$. Klaproth obtained (Beitr., v. 193) $\dddot{\mathrm{S}}$ 22·0, $\dot{\mathrm{Zn}}$ 27·5, $\dot{\mathrm{Mn}}$ 0·5, $\dot{\mathrm{H}}$ 50·0=100.

Pyr., etc.—Yields water. On charcoal with soda gives a zinc coating, and a sulphid which tarnishes silver. Easily soluble in water.

Obs.—This salt is formed by the decomposition of blende, and is found in the passages of mines. It occurs at the Rammelsberg mine near Goslar, in the Harz; at Schemnitz in Hungary; at Fahlun in Sweden; and at Holywell in Wales. It is not of common occurrence.

It is manufactured for the arts, and is very extensively employed in medicine and dyeing. White vitriol, as the term is used in the arts, is the sulphate of zinc in a granular state, like loaf sugar, produced by melting and agitation while cooling.

The name *Gallitzenite*, which has priority, was given the mineral by Beudant from a popular German name *Galitzenstein*. But although so called in Germany, zinc vitriol is not a stone from Galicia (Poland), as the word implies, while it is eminently a product of the mines of Goslar in the Harz. Haidinger's name *Goslarite* is therefore adopted for the species.

667. BIEBERITE. Cobalt Vitriol *Sage*, J. de Phys., xxxix. 53, 1791. Kobaltvitriol *Kopp*, Gehlen's J., II. vi. 157, 1808. Red Vitriol. Sulphate of Cobalt. Rhodhalose *Beud.*, Tr., ii. 481, 1832. Bieberit *Haid.*, Handb., 489, 1845.

Monoclinic. Usually in stalactites and crusts, investing other minerals.

G.=1·924, artificial crystals, Schill. Lustre vitreous. Color flesh- and rose-red. Subtransparent—translucent. Friable. Taste astringent.

Comp.—$\dot{\mathrm{Co}}\dddot{\mathrm{S}}+7\dot{\mathrm{H}}$=Sulphuric acid 28·4, oxyd of cobalt 25·5, water 46·1=100. Analyses 1, J. H. Kopp (Gehlen's J., II. vi. 157); 2, Winkelblech (Ann. d. Pharm., xiii. 265); 3, Beudant l. c.); 4, 5, Schnabel (Ramm. 4th Suppl., 118):

		$\dddot{\mathrm{S}}$	$\dot{\mathrm{Co}}$	$\dot{\mathrm{H}}$
1.	Bieber	19·74	38·71	41·55=100 Kopp.
2.	"	29·05	19·91	46·83, $\dot{\mathrm{Mg}}$ 3·86=99·65 Winkelblech.
3.	"	30·2	28·7	41·2, $\dot{\mathrm{Fe}}$ 0·9 Beudant.
4.	Siegen	28·81	23·30	45·22, $\dot{\mathrm{Ca}}$ 0·43, $\dot{\mathrm{Mg}}$ 0·88, Cl 0·09, insol. 1·14=100·12 Schn.
5.	"	20·84	16·50	38·13, $\dot{\mathrm{Ca}}$, $\dot{\mathrm{Mg}}$ *tr.*, Cl 0·05 insol. 24·04=100 Schn.

Kopp's analysis corresponds to $\dot{\mathrm{Co}}^2\dddot{\mathrm{S}}+8\dot{\mathrm{H}}$; but the existence of such a compound is very doubtful. The artificially prepared cobalt vitriol has the composition above given.

Pyr., etc.—In a matrass yields water, and when strongly heated, sulphurous acid Communicates a blue color to glass of borax.

Obs.—In the rubbish of old mines at Bieber, near Hanau; at Leogang in Saltzburg; at Tres Puntos, near Copiapo, Chili.

Beudant's name *Rhodhalose* is not an admissible derivative from 'ροδόεις, *rose-colored*, and ἅλς, *salt*, and is unmineralogical in its termination; it should have been *Rhodohalite*. Instead of making it right (in which case it would be no longer Beudant's name), it appears better to adopt the name applied by Haidinger, derived from the longest known locality.

668. MORENOSITE. Nickel-Viktril, Vitriolum ferrum & niccolum continens ("of a deep green color, with Kupfernickel, in Cobalt mines") *Cronst.* (the discov. of the metal Nickel), Min., 114, 1758. Niccolum vitriolatum (interdum e mineris sulphuratis fatiscentibus genitum) *Bergm.*, Sciagr., 50, 1782. Sulfato de niquel (fr. Galicia) *D. A. Casares*, 1849, A. M. Alcibar, in Revista Minera, Madrid, 305, 1850. Sulfato de nickel, Morenosita, *Casares*, ib., 176, March, 1851. Nickel Vitriol *T. S. Hunt*, this Min., 679, 1850, Logan's G. Rep. Can., 1863. Pyromeline *v. Kob.*, Gel. Anz. Münch., xxxv. 215, 1852, J. pr. Ch., lviii. 44.

In acicular crystals and thin prisms. Also fibrous; and as an efflorescence.

H.=2—2·25. G.=2·004, Fulda. Lustre vitreous. Color apple-green to greenish-white. Streak white, faintly greenish. Soluble; taste metallic astringent.

Comp.—$\dot{N}i\,\dddot{S}+7\,\dot{H}$=Sulphuric acid 28·5, oxyd of nickel 26·7, water 44·8=100. Analyses 1, 2, Fulda and Körner (Ann. Ch. Pharm., cxxxi. 217):

	$\dddot{S}$	$\dot{N}i$	$\dot{H}$	$\dddot{As}$
1. Riechelsdorf	28·54	26·76	44·48	0·27=100 Fulda.
2. "	28·42	26·59	44·83	0·24=100·08 Körner.

In the mineral from Galicia, on which the species was instituted, the nickel vitriol, according to Casares (l. c.), was mixed with a little sulphate of copper and iron; while that of Canada, according to Hunt, appeared to be pure nickel vitriol.

Pyr., etc.—B.B. in tube gives water, strongly acid, swells up, and hardens, becoming yellow and opaque. On charcoal glows strongly and evolves sulphurous acid With borax and phosphorus salt gives a distinct nickel reaction The Riechelsdorf mineral colors the outer flame blue, from the presence of arsenic.

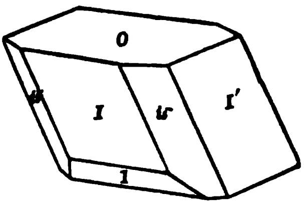
Obs.—A result of the alteration of nickel ores. Occurs near Cape Hortegal, in Galicia, Spain, on magnetite, with which some millerite is mixed; at Riechelsdorf, in Hesse; as an earthy crust, mountain-green in color, with native bismuth and arsenical nickel, at the Friedens mine near Lichtenberg in Bayreuth (pyromeline). Also in acicular crystals and crusts at Wallace mine, Lake Huron, upon a sulphuret of nickel and iron; at the Gap nickel mine, Lancaster Co., Pennsylvania.

Named by Casares after Mr. Moreno, of Spain. A. M. Alcibar states that Prof. Casares sent a communication on this mineral to the Société de Pharmacie of Paris in 1849, which was not published.

669. CHALCANTHITE. Χάλκανθον, Chalcanthum pt., *Dioscor.*, *Plin.*, Atramentum cœruleum *Agric.*, *Gesner*. Vitriolum Cupri=V. Cypri=V. Veneris, *Wall.*, *Cronst.* Sulphate of Copper, Blue Vitriol, Copper Vitriol. Kupfervitriol *Germ.* Couperose bleue, Cuivre sulfaté, *Fr.* Vitriolo di Rame *Ital.* Cyanose *Beud.*, Tr., ii. 486, 1832. Chalkanthit *v. Kobell*, Tafeln, 31, 1853.

Triclinic. $O \wedge I=109°\ 32'$, $O \wedge I'=127°\ 40'$, $I \wedge I'=123°\ 10$, $O \wedge 1=125°\ 38'$, $I \wedge 1=126°\ 10'$, $O \wedge i\text{-}\bar{i}=120°\ 50'$, $O \wedge i\text{-}\breve{i}=103°\ 27'$ and $76'\ 33'$. Cleavage: I imperfect, I' very imperfect. Occurs also amorphous stalactitic, reniform.

541



H.=2·5. G.=2·213. Lustre vitreous. Color Berlin-blue to sky-blue, of different shades; sometimes a little greenish. Streak uncolored. Subtransparent—translucent. Taste metallic and nauseous. Somewhat brittle.

Comp.—$\dot{C}u\,\overline{S} + 5\,\dot{H}$=Sulphuric acid 32·1, oxyd of copper 31·8, water 36·1=100. Often mixed with melanterite. Bluish crystals from mud at the Cronebane copper mine of Wicklow contain, according to Mr. Mallet, 34·2 of sulphate of iron to 65·7 of sulphate of copper.

Pyr., etc.—In the closed tube yields water, and at a higher temperature sulphuric acid. B.B. with soda on charcoal yields metallic copper. With the fluxes reacts for copper. Soluble in water; a drop of the solution placed on a surface of iron coats it with metallic copper.

Obs.—Blue vitriol is found in waters issuing from mines, and in connection with rocks containing chalcopyrite, by the alteration of which it is formed. Some of its foreign localities are the Rammelsberg mine near Goslar in the Harz; Fahlun in Sweden; at Parys mine, Anglesey; at various mines in Co. of Wicklow; formerly in crystals an inch long at Ting Tang mine in Gwennap; also Rio Tinto mine, Spain. The waters of the Rio Tinto mine have yielded annually 1,800 cwt. of copper, consuming 2,400 cwt. of iron. At Wicklow about 500 tons of iron were laid in the pits at one time, and in about 12 months the bars were dissolved, and each ton of iron yielded 1½ to 2 tons of a reddish mud which was *cement* copper, containing for every ton 16 cwt. of pure copper. It has been observed at Vesuvius among the products of the eruption of 1855.

Found at the Hiwassee copper mine, also in large quantities at the Isabella and other mines, in Polk Co., Tennessee, 30 m. from Cleveland; at the Canton mine, Georgia; at Copiapo, Chili, with stypticite.

When purified it is employed in dyeing operations, and in the printing of cotton and linen, and for various other purposes in the arts. It is manufactured mostly from old sheathing, copper trimmings, and refinery scales.

On the ancient *chalcanthum* see p. 645. Beudant's name *cyanose* (with *cyanosite* derived from it, from κυανος) is rejected like other names in which the terminal *s* of the Greek is retained. Moreover *chalcanthite*, meaning *flowers of copper*, is old and good.

670. CYANOCHROITE. Cianocroma *Scacchi*, Mem. Vesuv., 191, 1855.

Monoclinic. $C=75°\ 30'=O \wedge i\text{-}i$, $I \wedge I=108°\ 12'$, $O \wedge 1\text{-}\grave{\imath}=153°\ 56'$, $O \wedge 1\text{-}i=141°\ 47'$, $O \wedge 2\text{-}i=116°\ 49'$; also plane 2-ì. Occurs as a crust, and crystals obtained by solution and evaporation. Color clear blue.

Comp.—According to Scacchi, a hydrous sulphate of potash and copper; $(\frac{1}{2}\dot{C}u + \frac{1}{2}\dot{K})\overline{S} + 3\dot{H}$.

Obs.—From the saline crusts formed on the lavas during the eruption of Vesuvius in 1855.

Named in allusion to the color from κυάνος, *blue*, and χρόα, *color*. Scacchi's name has been changed to the above, in order to secure the termination *ite* and avoid ambiguity (the mineral containing no chrome).

---

671. ALUNOGEN.

Hydro-trisulfate d'alumine *Beud.*, Tr., 449, 1824. Davite (?) *Mill.*, Quart. J., 1828. Alunogene *Beud.*, Tr., ii. 488, 1832. Solfatarite pt. *Shep.*, Min., 188, 1835. Keramohalit *Glocker*, Grundr., 689, 1839. Saldanite *Huot*, Min., ii. 451, 1841. Stypterit *Glocker*, Syn., 297, 1847. Halotrichit pt. *Hausm.*, Handb., ii. 1174, 1847 (not Halotrichit *Glocker*). Schwefelsaure Thonerde. Sulphate of Alumina.

Monoclinic, Jurasky. In six-sided tables with two angles of 92° and four of 134°. Usually in delicate fibrous masses or crusts; also massive.

H.=1·5—2. G.=1·6—1·8. Lustre vitreous—silky. Color white, or tinged with yellow or red. Subtranslucent—subtransparent. Taste like that of common alum.

Comp.—${\rm \bar{A}l}\,\dddot{\rm S}^3+18\,{\rm \dot{H}}$=Alumina 15·4, sulphuric acid 36·0, water 48·6=100. **Analyses:** 1, 2 Boussingault (Ann. Ch. Phys., xxx. 109); 3, Herapath (Ch. 11. Puster V., Tyrol	36·0	15·8	48·4	——	——	——	——=100·2 Barth.

[a] And loss.

Beudant obtained in his analysis of a specimen from Guadaloupe, the first made of the species (Tr., 449, 1832), $\dddot{\rm S}$ 39·94, ${\rm \bar{A}l}$ 16·76, ${\rm \dot{H}}$ 36·44, potash alum 4·58, green vitriol 1·94, which gives 12 ${\rm \dot{H}}$ instead of 18 ${\rm \dot{H}}$. The other analyses agree well in the latter, and the difference is probably an error.

Davite N. Mill (Brandes Q. J., xxv. 382, 1828) from a hot spring at Chiwachi, a day's journey from Bogota, afforded him $\dddot{\rm S}$ 28·8, ${\rm \bar{A}l}$ 15·0, ${\rm \dot{H}}$ 51·8, ${\rm \bar{F}e}$ 1·2, with earthy matters 3·2=100. Requires investigation. Anal. 10 is of the *keramohalite* of Jurasky, from near Königsberg.

Pyr., etc.—Yields water, and at a higher temperature sulphuric acid, in the closed tube. Gives a fine blue with cobalt solution. Soluble in water.

Obs.—This species, a hydrous sulphate of alumina, results both from volcanic action, and the decomposition of pyrites in coal districts and alum shales, and occurs at the localities above mentioned, besides many others. The Pasto mineral was from the crater of a volcano. It has been observed by Scacchi at Vesuvius; at Königsberg, Hungary, it occurs in thick druses with iron vitriol. It is found as an efflorescence in numerous places in the United States. A white fibrous alunogen (?) occurs abundantly at Smoky Mtn., Jackson Co., N. C., where, it is said, tons may be obtained.

This species was made known by Beudant, and by him first named *Alunogen*. The word is a cross between French and Greek, and therefore objectionable; but not worse than some others of minerals that are accepted. Should *davite* turn out to be the same thing, this name would have the precedence in time; but still it could not claim recognition on the basis of an analysis proved to be so greatly in error.

672. COQUIMBITE.

Neutrales schwefelsaures Eisenoxyd *G. Rose*, Pogg., xxvii. 309, 1833 White Copperas. Coquimbit *Breith.*, Handb., 100, 1841.

Hexagonal. Prisms usually with the terminal edges deeply replaced. $O \wedge 1=151°$, $I \wedge 1=119°$, $1 \wedge 1=128° 8'$. Cleavage: *I*, imperfect. Also in fine granular masses.

H.=2–2·5. G.=2–2·1. Color white, yellowish, brownish, sometimes with a pale violet tint. Taste astringent.

Comp.—${\rm \bar{F}e}\,\dddot{\rm S}^3+9\,{\rm \dot{H}}$=Sulphuric acid 42·7, sesquioxyd of iron 28·5, water 28·8=100 **Analyses.** 1, 2, H. Rose (l. c.):

	$\dddot{\rm S}$	${\rm \bar{F}e}$	${\rm \bar{A}l}$	${\rm \dot{C}a}$	${\rm \dot{M}g}$	${\rm \ddot{S}i}$	${\rm \dot{H}}$
1. *Crystalline*	43·55	24·11	0·92	0·73	0·32	0·31	30·10=100·04 Rose.
2. *Granular*	43·55	25·21	0·78	0·14	0·21	0·37	29·98=100·24 Rose.

Pyr., etc.—B.B. resembles melanterite. Wholly soluble in cold water; if the solution be heated, sesquioxyd of iron is copiously precipitated. Dilute muriatic acid dissolves all except the silica.

Obs.—Forms a bed in a feldspathic or trachytic rock, in the province of Coquimbo, about half a day's journey from Copiapo. The bed of salt is on the increase, and is probably derived from decomposing sulphids. Pits 20 ft. deep have been formed in it by the people of the country. Occurs also in Bolivia near Calama, constituting the greater part of a large hill.

Observed by Scacchi about fumaroles after the eruption of Vesuvius in 1855, partly in a brownish friable crust, which, by solution and evaporation, afforded yellow *hexagonal* crystals; also as a yellowish crust, in many parts tinged green, compact in texture, with the lustre of a surface of fracture very bright.

Grailich states (Ber. Ak. Wien, xxviii. 272, 1858) that a specimen of coquimbite from Copiapo in the museum at Vienna has the optical characters of his rœmerite, and therefore cannot be hexagonal, and he suggests that the two minerals may be identical.

A related ochre-yellow mineral from Algodonbai in Bolivia, afforded v. Bibra (J. pr. Ch., xcvi. 206) $\dddot{S}$ 30·23, $\overline{F}e$ 43·89, $\dot{C}a$ 4·21, $\dot{H}$ 21·20, $\dot{C}u\,\dot{P}$ *tr.*=99·53; which, if the lime be separated as gypsum (10·21 p. c.), becomes $\dddot{S}$ 50·34, $\overline{F}e$ 27·80, $\dot{H}$ 21·86=100. It is partly soluble in water, but the solution contains no iron.

ALUM AND HALOTRICHITE GROUPS.

Groups of Tersulphates having the ratio of base and acid, and also of $\dot{R}$, $\overline{R}$, 1 : 3; all very soluble, and having more or less the astringent taste of common alum. H.=2—2·5. G.=1·56—2. The Alums have 24 $\dot{H}$ to 4 $\dddot{S}$, and are isometric; the Halotrichites have 22 $\dot{H}$ instead of 24 $\dot{H}$, and are not isometric, being either orthorhombic or monoclinic.

The species here included are not easily distinguishable by the taste or external characters, and hence early authors on minerals include all under one or two names. The old synonymy and the history of the species are therefore more conveniently given here than under the several subdivisions of the group.

Στυπτηρία *Gr.* Alumen *Plin.* [embracing vitriols as well as the alums]. Σχιστὴ στυπτηρία *Dioscor.* [embracing the fibrous or feathery kinds, Σχιστὴ being from σχίζω, *I cut*, and alluding to the easy subdivision into fibres]. Τριχίτης *Dioscor.* [fr. θρίξ, *hair*, it embracing capillary kinds]. Alumen fossile, *Germ.* Alaun, *Gesner*, Foss., 1565 [vitriols being excl., and comprising the var. A. candidum Neapolitanum (fr. Naples), A. capillare, ib., A. Placodes (latas crustas habens), ib., etc.]. Alun, Alumen [including var. α solidum, β crystallisatum, γ plumosum, or Fjäder-Alun], *Wall.*, Min., 161, 1747. Alun, Argilla acido vitrioli imbuta, *Cronst.*, 115, 1758. Argilla vitriolata [= Sulphate of Alumine] *Bergm.*, Sciagr., 1782. Alaun, Haarsalz, Federalaun [all as one species, or if two, without right distinctions], *Wern., and other Min. before* 1800. Alumine sulfatée alkaline *H.*, Tr., ii. 278, 1801 [citing Vauquelin's anal. of potash-alum, but including all alums].

In 1795 Klaproth proved (Beitr., i. 311), and in 1792 Breislak (Essais Min. sur la Solfatara, etc.), that some alum (that of Miseno and the Solfatara, near Naples) was *potash-alum.* In 1802 Klaproth showed (Beitr.. iii. 102) that the *Federalaun* of Freyenwald was *iron-alum.* Beudant ascertained that there was a native alum-like mineral which had the constitution attributed last century to true alum—that is, was a simple *sulphate of alumina*, without an alkali or other protoxyd (Tr., 449, 1824). Grüner, in 1821 (Gilb. Ann., lxix. 218), made known a native *ammonia-alum;* Thomson, in 1828 (Ann. Lyc. N. Y., iii. 19, 1828), a native *soda-alum;* A. A. Hayes, in 1845 (Am. J. Sci., xlvii. 360), a *magnesia-alum.*

673. TSCHERMIGITE. Ammonia Alum. Ammoniakalaun, Ammonalaun, *Germ.* Ammonalun *Beud.*, ii. 497, 1832. Tschermigit *v. Kobell*, Tafeln Bestimm., 1853.

In octahedrons and fibrous.

H.=1—2. G.=1·50. Lustre vitreous. Color white. Transparent to translucent.

Comp.—$NH^4O\,\dddot{S}+\overline{Al}\,\dddot{S}^3+24\,\dot{H}=(\frac{1}{4}\,(NH^4O)^3+\frac{3}{4}\,\overline{Al})\,\dddot{S}^3+18\,\dot{H}$=Sulphate of ammonia 14·6, sulphate of alumina 37·8, water 47·6=100.

Analyses: 1, Pfaff (Handb. An. Ch., ii. 47); 2, Lampadius (Gilb. Ann., lxx. 182, lxxiv. 183); 3 Stromeyer (Pogg., xxxi. 137):

	$\dddot{S}$	$\bar{A}l$	NH^4O	$\dot{H}$	$\dot{M}g$
1. Tschermig	36·00	12·14	6·58	45·00	0·28=100 Pfaff.
2. "	38·58	12·34	4·12	44·96	——=100 Lampadius.
3. "	36·065	11·602	3·721	48·390	0·115=99·893 Stromeyer.

Pyr., etc.—In the closed tube yields water and sulphate of ammonia; B.B. sublimes; on charcoal gives a coating of sulphate of ammonia, and leaves a residue which gives a fine blue with cobalt solution; with soda gives ammonia fumes, and the reaction for sulphuric acid.

Obs.—From Tschermig, Bohemia. This salt is manufactured from the waste of gas works, and used extensively in place of potash alum.

674. KALINITE. Potash Alum. Native Alum. Kalialaun, Kalinischer Alum, Kalinischer Alumsulphat, *Germ.* Kalinite *Dana.*

Isometric. Usually fibrous or massive, or in mealy or solid crusts.

H.=2—2·5. G.=1·75. Lustre vitreous. Color white. Transparent to translucent.

Comp.—$\dot{K}\dddot{S}+\bar{A}l\dddot{S}^3+24\dot{H}=(\frac{1}{4}\dot{K}^3+\frac{3}{4}\bar{A}l)\dddot{S}^3+18\dot{H}$=Sulphate of potash 18·4, sulphate of alumina 36·2, water 45·5=100.

Pyr., etc.—B.B. fuses in its water of crystallization, and froths, forming a spongy mass; with cobalt solution an intense blue; on charcoal gives a hepatic mass. Soluble in from 16 to 20 times its weight of cold water, and in little more than its weight of boiling water.

Obs.—Effloresces on argillaceous minerals, and more particularly alum slate. Whitby in Yorkshire is a noted locality, also Hurlet and Campsie near Glasgow. Also obtained at the volcanoes of the Lipari isles and Sicily. Cape Sable, Maryland, affords large quantities of alum annually In the caves of the Unaka Mts., Eastern Tennessee, especially at Sevier, masses a cubic foot in size may be obtained; also in the "Black Slate" of Middle Tennessee; and in caves along the valleys and gorges of the streams in De Kalb, Coffee, and Franklin Cos., Tenn. (Safford).

675. VOLTAITE. Voltaite *A. Scacchi*, Ac. Sci. Nap., 1840.

Isometric. In octahedrons, cubes, dodecahedrons, and combinations of these forms.

Lustre resinous. Color dull oil-green, greenish-black, brown, or black Streak grayish-green. Opaque.

Comp.—$\dot{F}e\dddot{S}+\bar{F}e\dddot{S}^3+24\dot{H}$, Scacchi,=$\dot{F}e\dddot{S}$ 15·4, $\bar{F}e\dddot{S}^3$ 40·6, $\dot{H}$ 44·0=100; but not from a complete analysis. Dufrénoy's analysis (Ann. d. M., III. ix. 165) is not correct according to Scacchi (Mem. G. Camp. Napoli, 89, 1849).

Abich has obtained an artificial salt of similar characters, which has the formula $(\frac{1}{3}(\dot{F}e,\dot{K})^3+\frac{2}{3}\bar{F}e)\dddot{S}^3+4\dot{H}$, and the composition:

$\dddot{S}$ 48·32 $\bar{A}l$ 2·20 $\bar{F}e$ 17·65 $\dot{F}e$ 11·60 $\dot{N}a$ 6·25 $\dot{K}$ 0·4 $\dot{H}$ 15·94

a little of the iron being replaced by aluminum. It is supposed that voltaite corresponds to it essentially in composition.

Paulinyi has found crystals of a similar compound at Kremnitz. They afford the formula (Tschormak, Anz. Ak. Wien, 1867, 218) $(\frac{1}{4}(\dot{F}e,\dot{K})^3+\frac{3}{4}\bar{F}e)\dddot{S}^3+4\frac{1}{2}\dot{H}$, with $\dot{F}e:\dot{K}=4:1$, and a little aluminum replacing iron.

Pyr., etc.—Soluble in water with difficulty, and at the same time decomposes.

Obs.—This species was first observed at the Solfatara near Naples, by Breislak (1792). It has been found by F. Ulrich at the Rammelsberg mine near Goslar. The last contains protoxyd of manganese, as well as of iron.

676 BLAKEITE *Dana*, Min., 1850. J. H. Blake has described an iron-sulphate from Coquimbo, which he refers to coquimbite; but it occurs in regular octahedrons, and assumed the same form on solution and recrystallization. He obtained in an analysis $\dddot{S}$ 41·37, $\bar{F}e$ 26·79, $\bar{A}l$ 1·05, $\dot{M}g$ 0·30, $\ddot{S}i$ 0·82, $\dot{H}$ 29·40=99·68. Requires further investigation.

677. MENDOZITE. Soda Alum. Natronalaun, Natrumalaun, *Germ.* Natronalun *Huot*, ii 448, 1841. Solfatarite pt. *Shep.*, Min., ii. 187, 1835 (not in Min. of 1857). Mendozite *Dana.*

In white fibrous masses.

H.=3, and G.=1·88, Thomson. Externally white or pulverulent. Some resemblance to fibrous gypsum, but harder.

Comp.—$\dot{N}a\,\dddot{S}+\ddot{\bar{A}}l\,\dddot{S}^3+22\,\dot{H}$=Sulphate of soda 16·1, sulphate of alumina 39·0, water 44·9=100; or, Sulphuric acid 36·8, alumina 11·7, soda 7·1, water 44·9=100. Analysis by Thomson (Ann. Lyc. N. Y., 1828):

St. Juan near Mendoza $\dddot{S}$ 37·70 $\ddot{\bar{A}}l$ 12·00 $\dot{N}a$ 7·96 $\dot{H}$ 41·96=99·62.

Pyr., etc.—Resembles ordinary alum.

Obs.—Occurs near Mendoza, east of the Andes.

Thomson found for the composition of a soda alum from Southern Peru which he called Subsesquisulphate of Alumina (Phil. Mag., III. xxii. 188), $\dddot{S}$ 32·95, $\ddot{\bar{A}}l$ 22·55, $\dot{N}a$ and $\dddot{S}$ 6·50, $\dot{H}$ 39·20 =101·20. G.=1·584.

Shepard states in Am. J. Sci., xvi. 203, 1829, that the alum of the island of Milo is a soda alum related to Thomson's; but in vol. xxii. 387, ib., he admits a doubt, on the ground of Hartwall's analysis of a Milo alum, which makes it *Alunogen* (q. v.). Shepard's name solfatarite (which he has since rejected) was based upon its occurring in solfataras, and not in the Naples solfatara, to which no allusion is made in his edition of 1835; and under it he gave three analyses of alunogen, with the one of *soda-alum* by Thomson. The Mendoza mineral is not from a solfatara.

678. PICKERINGITE. *Hayes*, Am. J. Sci., xlvi. 360, 1844. Magnesia Alum *ib.* Magnesialaun, Talkerde-Alaun, *Germ.*

Monoclinic? In fine acicular crystals; long fibrous masses; and in efflorescences.

H.=1. Lustre silky. Color white, yellowish. Becomes pulverulent and white on exposure. Taste bitter—astringent.

Comp.—$\dot{M}g\,\dddot{S}+\ddot{\bar{A}}l\,\dddot{S}^3+22\,\dot{H}$=Sulphuric acid 37·3, alumina 12·0, magnesia 4·6, water 46·1. Analyses: 1, A. A. Hayes (l. c.); 2, How (J. Ch. Soc., II. i. 200):

	$\dddot{S}$	$\ddot{\bar{A}}l$	$\dot{F}e$, $\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{K}$	$\dot{H}$
1. Iquique	36·32	12·13	0·43	4·68	0·13	—	45·45, H Cl 0·60=99·74 Hayes.
2. Newport, N. S.	36·38	10·64	0·58	4·79	—	0·23	45·06, $\dot{C}o$ 0·06, $\dot{N}i$ 0·14, slate 0·72=99·57 H.

In two other trials How found for $\dddot{S}$ 36·36, 36·59, and for $\dot{H}$ 46·16, 46·07.

Pyr., etc.—In the matrass yields water, and acts like other alums. Tastes like ordinary alum.

Obs.—From near Iquique, in Peru; also from N. Scotia, in Newport, on the bank of the Meander, as an efflorescence on the slate or shale (Silurian) of a sheltered cliff, where it results from the action on the shale of decomposing pyrite—and probably a kind containing traces of cobalt and nickel. How observes that the fibres in this mineral are oblique in crystallization, and that it contains only 22 $\dot{H}$; and that it is therefore not a true alum.

679. APJOHNITE. Manganese Alum *Apjohn*, Phil. Mag., xii. 103, 1838. Manganalaun Apjohnit *Glocker*, Syn., 298, 1847.

In fibrous or asbestiform masses, white, and with a silky lustre.

Comp.—$\dot{M}n\,\dddot{S}+\ddot{\bar{A}}l\,\dddot{S}^3+24\,\dot{H}$=Sulphate of manganese 16·3, sulphate of alumina 37·0, water 46·7=100. How suggests the formula $\dot{M}n\,\dddot{S}+\ddot{\bar{A}}l\,\dddot{S}^3+22\,\dot{H}$, which would correspond to 44·54 p. c. of water and 35·96 $\dddot{S}$, supposing some loss of the sulphuric acid in the heating to determine the water.

Analysis: Apjohn (Phil. Mag., l. c.):

$\dddot{S}$ 32·79 $\ddot{\bar{A}}l$ 10·65 $\dot{M}n$ 7·33 (=$\dot{M}n$ 6·60) $\dot{H}$ 48·15 $\dot{M}g\,\dddot{S}$ 1·08=100.

Pyr.—Nearly the same as for ordinary alum, but gives with fluxes a reaction for manganese
Obs.—From Lagoa Bay in South Africa.

680. BOSJEMANITE. Manganese Alum pt., Mangano-magnesian Alum. Bosjemanite *Dana*

Monoclinic? In silky acicular or capillary crystallizations; and as crusts and efflorescences. Taste like that of ordinary alum, but less strong.

Comp.—$(\dot{\mathrm{M}}\mathrm{n}, \dot{\mathrm{M}}\mathrm{g})\dddot{\mathrm{S}}+\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dddot{\mathrm{S}}^3+22\,\dot{\mathrm{H}}$ (How)=if $\dot{\mathrm{M}}\mathrm{n}:\dot{\mathrm{M}}\mathrm{g}=1:2$, Sulphuric acid 36·82, alumina 11·83, protoxyd of manganese 2·73, magnesia 3·06, water 45·56=100. Analyses: 1, Stromeyer (Pogg., xxxi. 137); 2, J. L. Smith (Am. J. Sci., II. xviii. 379); 3, E. Schweizer (Kenng. Uebers., 1859, 12):

	$\dddot{\mathrm{S}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1. Bosjeman R., Afr.	36·77	11·52	——	2·17	3·69	——	——	45·74, KCl 0·20=100 S.
2. Utah	35·85	10·40	0·15	2·12	5·94	——	0·20	46·00=100·66 Smith.
3. Maderan Vall.	35·96	10·55	1·06	2·51	3·74	0·27	0·58	44·26, $\dot{\mathrm{C}}\mathrm{u}$ 0·22, insol. 1·12=100.

In the last there was some ammonia with the water.

Pyr., etc.—As under apjohnite.

Obs.—It covers the floor of a cave near Bosjeman river in Southern Africa, to a depth of six inches; the roof is a reddish quartzose conglomerate, containing magnesia and pyrites; it rests on a bed of epsomite, 1½ inches thick; also found in Maderan valley in Canton Uri, Switzerland (called *keramohalite* by Schweizer); and at Alum Point near Salt Lake, in Utah. This Utah mineral was made a manganesian alum by Dr. Gale (Am. J. Sci., II. xv. 434, 1853).

681. HALOTRICHITE. Federalaun von Freyenwalde (with anal. showing it to be an iron alum) *Klapr.*, Beitr., iii. 102, 1802. Eisenalaun *Germ.* Iron Alum. Halotrichit *Glocker*, Grundr., 691, 1839. Hversalt *Forchhammer*, Jahresb., xxiii. 263, 1843. Halotrichine *Scacchi*, Mem. Geol. Camp. Nap., 84, 1849.

Silky fibrous. Yellowish-white. Taste inky-astringent. Becomes dull and pulverulent on exposure.

Comp.—$\dot{\mathrm{F}}\mathrm{e}\,\dddot{\mathrm{S}}+\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dddot{\mathrm{S}}^3+22\,\dot{\mathrm{H}}$=Sulphuric acid 35·9, alumina 11·5, protoxyd of iron 8·1, water 44·5=100.

In the *Hversalt* of Forchhammer (l. c.) a small part of the alumina is replaced by sesquioxyd of iron, and of the protoxyd of iron by magnesia. Scacchi's *Halotrichine* (l. c.) may belong here; he writes for the formula $\dot{\mathrm{F}}\mathrm{e}\,\dddot{\mathrm{S}}+\frac{2}{3}\,\dddot{\bar{\mathrm{A}}}\mathrm{l}\,\dddot{\mathrm{S}}^3+18\,\dot{\mathrm{H}}$. If part of the iron is sesquioxyd it is like the hversalt.

Analyses: 1, Berthier (Ann. d. Mines, v. 257); 2, Rammelsberg (Pogg., xliii. 399)· 3, B. Silliman, Jr. (this Min., 226, 1850); 4, Arppe (An. Finske Min., 1857); 5, Phillips (Ann. Ch. Phys., xxiii. 322); 6, Forchhammer (l. c.); 7, Scacchi (l. c.):

	$\dddot{\mathrm{S}}$	$\dddot{\bar{\mathrm{A}}}\mathrm{l}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{H}}$
1. ———?	34·4	8·8	12·0	0·8	44·0=100 Berth.
2. Mörsfeld	36·03	10·91	9·37	0·23	43·03, $\dot{\mathrm{K}}$ 0·43=100 Ramm.
3. Oroomiah	33·81	10·62	9·15	——	41·61, $\dddot{\mathrm{S}}\mathrm{i}$ 8·34, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 1·05=99·58 S.
4. Finland	34·71	13·33	6·23	——	44·20=98·47 Arppe.
5. Hurlet	30·9	5·2	20·7	——	43·2=100 Phillips.
6. *Hversalt*	35·16	11·22	4·57	2·19	45·63, $\dddot{\bar{\mathrm{F}}}\mathrm{e}$ 1·23=100 Forchhammer.
7. *Halotrichine*	34·12	9·76	10·20	——	45·92=100 Scacchi.

Klaproth obtained for the "Feather alum" of Freyenwalde, Sulphuric acid and water 77, alumina 15·25, protoxyd of iron 7·50, potash 0·25=100.

Pyr., etc.—Fuses in its own crystallization-water, cracks open, and if strongly heated gives off sulphurous acid, leaving a brown residue; with the fluxes reacts for iron, and with soda on charcoal gives an hepatic mass.

Obs.—Occurs at Bodenmais and at Mörsfeld in Rhenish Bavaria. Also at Oroomiah, Persia, where the inhabitants use it for making ink of a fine quality; at Hurlet and Campsie near Glasgow; at Bjorkbackagard in Finland (anal. 4). Probably at Rossville, Richmond Co., N. Y. (Beck)

The *Hversalt* of Forchhammer is an allied alum from Iceland. *Halotrichine* is a silky alum from the Solfatara near Naples.

The name *Halotrichite* is from ἅλς, *salt*, and θρίξ, *hair*.

Berg-butter (*Beurre de Montagne*) is an impure alum or copperas efflorescence, of a butter-like consistence, oozing from some alum slates. A yellowish kind from Wetzelstein, near Saalfeld, afforded R. Brandes (Schw. J., xxxix. 417) $\dddot{\mathrm{S}}$ 34·82, $\overline{\mathrm{Al}}$ 7·00, $\dot{\mathrm{Fe}}$ 9·97, $\dot{\mathrm{Mg}}$ 0·80, $\dot{\mathrm{Na}}$ 0·72, ammonia 1·75, $\dot{\mathrm{H}}$ 43·50=99·00. Another, from the original locality at Irtisch in the Altai, gave Klaproth (Beitr., vi. 344) $\dddot{\mathrm{S}}$ 31·0, $\overline{\mathrm{Al}}$ 2·5, $\dot{\mathrm{Fe}}$ 6·0, $\dot{\mathrm{Mn}}$ 0·25, $\dot{\mathrm{Mg}}$ 6·25, $\dot{\mathrm{Ca}}$ 4·5, $\dot{\mathrm{Na}}$ 0·25, $\dot{\mathrm{H}}$ 49·25.

682. RŒMERITE. Rœmerit *Grailich*, Ber. Ak. Wien, xxviii. 272, 1858.

Monoclinic. *C*=78° 59′, *I* ∧ *I*, front,=101° 24′, *O* ∧ *I*=98° 30′ and 81° 30′, *O* ∧ *i-ì*=101° 1′, *O* ∧ *i-i*=90°, *I* ∧ *i-i*=129° 18′, Grailich. Cleavage: clinodiagonal perfect. Coarse granular, the grains partly crystallized.

H.=2·75. G.=2·15—2·18; mean of results 2·174. Lustre between greasy and vitreous. Color rust-brown to yellow. Translucent. Taste saline, astringent, vitriolic.

Comp.—O. ratio for $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\dddot{\mathrm{S}}$, $\dot{\mathrm{H}}$=nearly 1 : 3 : 12 : 12; $\dot{\mathrm{R}}\,\dddot{\mathrm{S}}+\overline{\mathrm{Fe}}\,\dddot{\mathrm{S}}^3+12\,\dot{\mathrm{H}}$. Mean of two analyses by Tschermak (l. c.):

	$\dddot{\mathrm{S}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Zn}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$	insol.
(½)	41·54	20·63	6·26	1·97	*tr.*	0·58	*tr.*	28·00	0·50=99·48.

Pyr., etc.—Probably the same as for copiapite. Reactions of iron and zinc.
Obs.—From the Rammelsberg mine near Goslar, along with copiapite.

---

683. COPIAPITE. Μίσυ *Diosc.* Misy (fr. Cyprus, etc.) *Plin.*, xxxiv. 31. Misy, *Germ.* Gelb Atrament (fr. Harz, etc.), *Agric.*, Nat. Foss., 218, 457, Interpr., 466, 1546. Pyr., etc.—Yields water, and at a higher temperature sulphuric acid. On charcoal becomes magnetic, and with soda affords the reaction for sulphuric acid. With the fluxes reactions for iron. In water insoluble.

Obs.—Common as a result of the decomposition of pyrite at the Rammelsberg mine, near Goslar in the Harz, and elsewhere.

This species is the yellow copperas long called misy, and it might well bear now the name *Misylite*. The description of Dioscorides is unsatisfactory. But that of Pliny, not over 25 years later, is good, and is as likely to represent the true μισυ of the Greeks; and that of Agricola is excellent, and was taken from Goslar specimens.

684. RAIMONDITE. Raimondit *Breith.*, B. H. Ztg., xxv. 149, 1866.

Hexagonal. In thin six-sided tables with removed basal edges, scale-like. Cleavage: basal, perfect.

H.=3—3·25. G.=3·190—3·222. Lustre pearly. Color between honey- and ochre-yellow. Streak ochre-yellow. Opaque.

Comp.—O. ratio $\dddot{\bar{R}}$, $\dddot{S}$, $\dot{H}$=6 : 9 : 7; $\dddot{\bar{F}}e^2\dddot{S}^3+7\dot{H}$=Sulphuric acid 35·0, sesquioxyd of iron 46·6, water 18·4=100.

Analysis: 1, Rube (l. c.):

	$\dddot{S}$	$\dddot{\bar{F}}e$	$\dot{H}$
1. Ehrenfriedersdorf	36·08	46·52	17·40=100.

Pyr., etc.—Probably the same as for copiapite. In water insoluble.

Obs.—From the tin mines of Ehrenfriedersdorf, in scales on cassiterite.

684A. PASTREITE *Norman* (Bergemann, Verh. nat. Ver. Bonn, 1866, 17), may be of the above species, if part of the iron is present as limonite. According to Bergemann, it occurs amorphous or reniform, of a yellow color, at Paillières, near Alais, Dept. of Gard, with cerussite, limonite, calcite, gypsum, fibroferrite; B.B. infusible; in muriatic acid easily soluble. The analyses gave (l. c.):

	$\dddot{S}$	$\ddot{S}i$	$\dddot{\bar{A}}s$	$\dddot{\bar{F}}e$	$\dot{P}b$	$\dot{H}$
1. *Yellow*	30·47	2·40	1·86	46·50	1·25	16·04, $\dddot{\bar{A}}l$, $\dot{M}n$, $\dot{C}a$ 0·89=99·41.
2. *Yellowish-brown*	30·55	—	2·05	52·80	—	13·95, $\dddot{\bar{A}}l$, $\dot{C}a$, sand 0·63=99·98.

Received by Dr. Bergemann from Dr. Normann, of Marseilles, who named it after President Pastré, of that city. It approaches jarosite (p. 660), except in the absence of alkalies.

685. FIBROFERRITE. *H. Rose*, Pogg., xxvii. 316, 1833. Fibroferrite *Prideaux*, Phil. Mag., III. 397, 1841. Stypticit *Hausm.*, Handb., ii. 1202, 1847. Copiapite *J. L. Smith*, Am. J. Sci., II. xviii. 375.

Delicately fibrous.

H.=1·5—2. G.=1·84, Smith. Lustre silky, pearly. Color pale yellow, or nearly white. Translucent.

Comp.—$\dddot{\bar{F}}e^3\dddot{S}^5+27\dot{H}$, Ramm.=Sulphuric acid 29·30, sesq. iron 35·15, water 35·55=100

Analyses: 1, H. Rose (l. c.); 2, 3, J. L. Smith (l. c.); 4, E. Tobler (Ann. Ch. Pharm., xcvi. 383) 5, Prideaux (l. c.); 6, F. Field (Q. J. Ch. Soc., xiv. 156); 7, Pisani (C. R., lix. 94):

	$\dddot{S}$	$\dddot{\bar{F}}e$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$

5. " "	28·9	34·4	—	—	36·7=100 Prideaux.
6. Chili, "	31·94	31·89	—	—	35·90=99·73 Field.
7. Paillières	29·72	33·40	—	*tr.*	36·88=100 Pisani.

Pyr., etc.—Same as for copiapite.

Obs.—From Copiapo, Chili, in delicately fibrous masses, associated with coquimbite; also from the mines of Paillières, in Gard, France.

The name alludes to the fibrous structure. There is no reason to doubt the identity of Prideaux's *fibroferrite* of 1841 with the mineral analyzed by Rose, Smith, and others, and which Hausmann named stypticite in 1847.

686. APATELITE. *Meillet*, Ann. d. M., IV. iii. 808, 1841.

In small friable nodules or balls. Color clear yellow. Resembles copiapite.

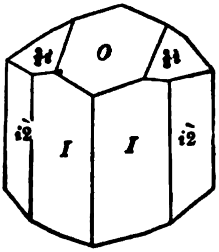
Comp.—$\text{Ꞙe}^3\dddot{\text{S}}^5+2\dot{\text{H}}$. Analysis by Meillet (l. c.):

$\dddot{\text{S}}$ 42·90 Ꞙe 53·30 $\dot{\text{H}}$ 3·96=100·16.

Occurs at Meudon and Auteuil, disseminated in an argillaceous bed connected with the plastic clay.

687. BOTRYOGEN. Rother Eisen-Vitriol *Berz.*, Afh., iv. 307, 1815. Red Iron Vitriol. Fer sulfaté rouge *Fr.* Botryogen *Haid.*, Pogg., xii. 491, 1828. Neoplase pt. *Beud.*, Tr., ii. 483, 1832. Botryt *Glock.*, Syn., 300, 1847.

542



Monoclinic. *C*=62° 26′, *I* ∧ *I*=119° 56′, *O* ∧ 1-ì=152° 1½′; *a* : *b* : *c*= 0·9188 : 1 : 1·5334. Observed planes as in the figure, with also 1-*i* (on acute solid angle of base), 1 (on acute edge of base), and *i*-ì. *O* ∧ *I*=113° 37′, *O* ∧ 1-*i*= 125° 31′, *O* ∧ 1=121° 4′, *I* ∧ *i*-2̀=160° 54′, *i*-2̀ ∧ *i*-2̀ =98° 16′, ⅔-ì ∧ ⅔-ì=141°, *O* ∧ ⅔-ì=160° 30′; *I* and *i*-2̀ vertically striated. Cleavage parallel to *I*. Crystals usually small. Often in reniform and botryoidal shapes, consisting of globules with a crystalline surface.

H.=2—2·5. G.=2·039. Lustre vitreous. Color deep hyacinth-red; massive varieties sometimes ochre-yellow; streak ochre-yellow, a little shining. Translucent. Taste slightly astringent.

Comp.—? $\dot{\text{F}}\text{e}^3\dddot{\text{S}}^3+3\,\text{Ꞙe}\,\dddot{\text{S}}^3+36\,\dot{\text{H}}$, Berz., $=(\tfrac{1}{4}\dot{\text{F}}\text{e}^3+\tfrac{3}{4}\text{Ꞙe})\dddot{\text{S}}^3+9\,\dot{\text{H}}$=Sulphate of protoxyd of iron 19·0, id. of sesquioxyd 48·3, water 32·7=100. Analyses: Gahn & Berzelius (l. c.):

	$\dddot{\text{S}}$	Ꞙe	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$
1.	36·53	26·50	5·69	2·76	
2.	37·87	24·77	8·95	0·91	
3.		25·45	6·92		30·90

from which he deduces, without having determined directly the protoxyd of iron:

	$\dot{\text{F}}\text{e}\,\dddot{\text{S}}$	$\dot{\text{F}}\text{e}\,\text{Ꞙe}\,\dddot{\text{S}}$	$\dot{\text{Mg}}\,\dddot{\text{S}}$	$\dot{\text{Ca}}\,\dddot{\text{S}}$	$\dot{\text{H}}$ and loss.
1.	6·77	35·85	26·88	2·22	28·28=100.
2.	6·85	39·92	17·10	6·71	31·42=100.
3.	48·3		20·8	—	30·9=100.

The sulphates of magnesia and lime are rejected as impurity, but with how much propriety is uncertain.

Pyr., etc.—B.B. intumesces and gives off water, producing a reddish-yellow earth. On charcoal becomes magnetic; with soda gives a hepatic mass. Remains unaltered if kept dry, but in a moist atmosphere it becomes covered with a dirty yellowish powder. Partly soluble in boiling water, leaving an ochreous residue.

Obs.—Occurs at the copper mine of Fahlun, in Sweden, coating gypsum or pyrite.

Named from *βότρυς, a bunch of grapes*, and *γεννάω, I make*. This last part of the name is bad and is well thrown aside by Glocker, who makes it *botryte*; *botryite* would be more correct.

---

688. ALUMINITE. Reine Thonerde (fr. Halle) *Wern.*, Ueb. Cronstedt, 176, 1780. Native Argill *Kirwan*, Min., i. 175. Aluminit *C. C. Haberle*, Der Mineralreich, etc., 1807; *Karst.*, Tab, 48, 1808. Hallite *Delameth.*, Min., ii. 1812. Websterite *Levy*, in Brooke, 1823. Hydrosulphate d'alumine, Websterite, *Beud.*, Tr., 449, 1824.

Reniform, massive; impalpable.

H.=1–2. G.=1·66. Lustre dull, earthy. Color white. Opaque. Fracture earthy. Adheres to the tongue; meagre to the touch.

Comp.—$\overline{\text{Al}}\,\dddot{\text{S}}+9\,\dot{\text{H}}$=Alumina 29·8, sulphuric acid 23·2, water 47·0=100. Analyses: 1, Stromeyer (Unters., 99); 2, Schmid (J. pr. Ch., xxxii. 495); 3, 4, Stromeyer (l. c.); 5, Dufrénoy (Min., ii. 1845, 366); 6, Dumas (ib.):

	$\dddot{\text{S}}$	$\overline{\text{Al}}$	$\dot{\text{H}}$
1. Halle	23·365	29·263	46·372=100 Stromeyer.
2. "	23·25	29·23	46·34, $\dot{\text{Ca}}$ 1·18=100 Schmid.
3. Morl, near Halle	23·68	30·98	45·34=100 Stromeyer.
4. Newhaven	23·37	29·87	46·76=100 Stromeyer.
5. Lunel Vieil	23·45	29·72	46·80=99·97 Dufrénoy.
6. Auteuil	23	30	47=100 Dumas.

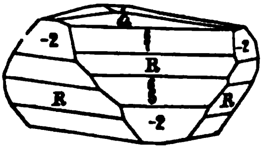
Pyr., etc.—In the closed tube gives much water, which, at a high temperature, becomes acid from the evolution of sulphurous and sulphuric acids. B.B. infusible. With cobalt solution a fine blue color. With soda on charcoal a hepatic mass. Soluble in acids.

Obs.—Occurs in connection with beds of clay in the Tertiary and Post-tertiary formations. First found in 1730 in the Garden of the Pædagogium at Halle; afterward suspected to be an artificial product, from a manufactory near by; subsequently found elsewhere in the plastic clay of the region, and proved to be native. Since discovered by Mr. Webster at Newhaven, Sussex, in reniform and botryoidal concretions, imbedded in ferruginous clay, which rests on the chalk strata; also under similar circumstances at Epernay, in Lunel Vieil, and Auteuil, in France.

689. ALUNITE. Alumen de Tolpha, quod primum fossum est in Italia, Pii 2di Pontificis temporibus (Piccolomini, 1458–1464), *Gesner*, Foss., 13, 1565. Romersk Alunsten *Wall.*, Min., 163, 1747. Alaunstein (fr. Tolfa) *Wern.*, Bergm. J., 376, 1789. Alumstone. Aluminilite *Delameth.*, T. T., ii. 113, 1797. Alun de Rome pt. *H.*, Tr., 1801. Pierre alumineuse de la Tolfa *Fr.* Alunite *Beud.*, 449, 1824. Alaun-Spath *Breith.*, Char., 1823.

Rhombohedral. $R \wedge R$=89° 10′, $O \wedge R$=124° 40′, Breith.; a=1·2523. Observed planes: R, O, and the rhombohedrons $\frac{6}{7}$, $\frac{1}{64}$, $-\frac{6}{5}$, and –2, Breith.

543



$O \wedge 2$=109° 4′　　$O \wedge \frac{1}{64}$=178° 42′

$O \wedge \frac{6}{5}$=119 57　　$\frac{6}{5} \wedge \frac{6}{5}$=82 26

$O \wedge \frac{6}{7}$=128 55　　$2 \wedge 2$=70 8

Cleavage: basal nearly perfect; R indistinct. Also massive, having a fibrous, granular, or impalpable texture.

H.=3·5–4. G.=2·58–2·752. Lustre of R vitreous, basal plane somewhat pearly. Color white, sometimes grayish or reddish. Streak white. Transparent—subtranslucent. Fracture flat conchoidal, uneven; of massive varieties splintery; and sometimes earthy. Brittle.

Comp., Var.—(*a*) Crystallized. (*b*) Fibrous, concretionary. (*c*) Massive, and moderately tender. (*d*) Hard, mainly from disseminated silica, which impurity sometimes amounts to 60 p. c. (*e*) Cavernous.

O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{S}$, $\dot{H}$=1 : 9 : 12 : 6. Formula, as usually written, $\dot{K}\dddot{S}+3\dddot{\bar{A}}l\dddot{S}+6\dot{H}$; or, making one-third of the water basic, $(\dot{K},\dot{H})^3\dddot{S}+3\dddot{\bar{A}}l\dddot{S}+4\dot{H}$=Sulphuric acid 38·53, alumina 37·13, potash 11·34, water 13·00=100. But A. Mitscherlich, in view of the results of its decomposition after heating (J. pr. Ch., lxxxiii. 465), it affording alum, which water will remove, and hydrated alumina, holds that the formula should be $\dot{K}\dddot{S}+\dddot{\bar{A}}l\dddot{S}^3+2\dddot{\bar{A}}l\dot{H}^3$, making it a compound of anhydrous alum and gibbsite.

Analyses: 1, Cordier (Ann. d. M., v. 203); 2, Mitscherlich (J. pr. Ch., lxxxiii. 464); 3, Rammelsberg (l. c.); 4, Mitscherlich (l. c., and ZS. G., xiv. 254); 5, Berthier (l. c.); 6, C. Descotils (Ann. d. M., i. 319); 7, Sauvage (ib., IV. x. 85); 8, Cordier (ib., iv. 205); 9, Fridau (Ann. Ch. Pharm., lxxvi. 106):

	$\dddot{S}$	$\dddot{\bar{A}}l$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	$\dot{H}$

9. Styria	35·3	40·8	—	—	8·5	15·4=100 Fridau.

From analysis 3, $\dddot{S}i$ 26·88 is excluded as impurity; from 5, $\dddot{S}i$ 26·5, $\dddot{\bar{F}}e$ 4·0, are excluded; from 7, $\dddot{S}i$ 19·0; from 8, $\dddot{S}i$ 28·40, $\dddot{\bar{F}}e$ 1·44. No. 11, by Fridau, as published in full, is $\dddot{S}i$ 50·71, $\dddot{S}$ 16·50, $\dddot{\bar{A}}l$ 19·06, $\dddot{\bar{F}}e$ 1·13, $\dot{K}$ 3·97, $\dot{H}$ 7·23, $\dot{C}a$ 0·56, $\dot{M}g$ 0·41, $\dot{K}$, $\dddot{S}i$ 0·31, $\dot{M}g\dddot{S}$ 0·09, Mg Cl 0·03=100.

For analysis of impure A. from Pic de Sancy, by J. Gautier-Lacroze, see C. R., lvii. 362.

Pyr., etc.—B.B. decrepitates, and is infusible. In the closed tube yields water, sometimes also sulphate of ammonia, and at a higher temperature sulphurous and sulphuric acids. Heated with cobalt solution affords a fine blue color. With soda and charcoal infusible, but yields a hepatic mass. Soluble in sulphuric acid.

Obs.—Forms seams in trachytic and allied rocks, where it has been formed as a result of the alteration of the rock by means of sulphurous vapors.

Met with at Tolfa, near Civita Vecchia, in the neighborhood of Rome, in crystals; at Montioni in Tuscany; at Muzsai and Bereghszasz in Hungary; on Milo, Argentiera, and Nevis, Grecian Archipelago; and at Mt. Dore, France.

The compact varieties from Hungary are so hard as to admit of being used for millstones. Alum is obtained from it by repeatedly roasting and lixiviating, and finally crystallizing by evaporation.

This species was first observed at Tolfa, near Rome, in the 15th century, by J. de Castro, a Genoese, who had been engaged in the manufacture of alum, from an alum-stone or "Rock-alum" found near Edessa in Syria. It was named *Aluminilite* by Delametherie in 1797, a long name well changed to *Alunite* by Beudant in 1824.

690. LÖWIGITE. Alaunstein *Römer*, ZS. G., viii. 246, 1856. Löwigit *A. Mitscherlich*, J. pr. Ch., lxxxiii. 474, 1861.

In rounded masses, similar to compact alunite.

H.=3–4. G.=2·58. Lustre feeble. Color pale straw-yellow. Slightly subtranslucent. Fracture perfectly conchoidal.

Comp.—O. ratio 1 : 9 : 12 : 9=$\dot{K}\dddot{S}+3\dddot{\bar{A}}l\dddot{S}+9\dot{H}$=Sulphuric acid 36·2, alumina 34·8, potash 10·7, water 18·3=100; or alunite with 9 $\dot{H}$ in place of 6 $\dot{H}$. 3. Tolfa	37·86	36·01	9·63	16·50=100[a] Mitscherlich.
4. " *cryst.*	36·94	34·02	10·38	16·72, $\ddot{Si}$ 1·94=100 Rammelsberg.
5. " "	37·67	34·69	10·58	17·06=100 Berthier.

[a] 0·07 organic substance, 3·21 silica, and 23·50 earthy matters removed.

Pyr., etc.—B.B. nearly like alunite. The water is expelled at a lower temperature than in alunite; and the compound resulting after heating, instead of containing a mixture affording alum and insoluble hydrated alumina, affords to water sulphate of potash and subsulphate of alumina. Mitscherlich hence writes for it the above formula, instead of one like his for alunite. Partially soluble in muriatic acid, while alunite is not at all so.

Obs.—Found in a coal bed at Tabrze in Upper Silesia, in compact lumps, having the lustre, color, and texture of the Solenhofen lithographic stone, but blackish externally from a coaly crust; also with alunite at Tolfa.

According to Rammelsberg's analysis, part at least of the crystallized alunite has the composition of löwigite.

691. JAROSITE. Gelbeisenerz *Ramm.*, Pogg., xliii. 132, 1838. Misy *Haid.*, Handb., 512, 1845. Vitriolgelb, Gelbeisenerz, *Hausm.*, Handb., 1205, 1847 [not Gelbeisenerz fr. Harz *Breith.*, Char., 1832]. Jarosit *Breith.*, B. H. Ztg., 1852. Moronolite *Shep.*, Suppl. Append. Min., p. iv. 1857.

Rhombohedral. $R \wedge R=88° 58'$; $O \wedge R=124° 32'$; $a=1·2584$. Cleavage: basal. Also fibrous, and granular massive. Also in nodules, or as an incrustation with a tuberose or coralloidal surface.

H.=2·5—3·5. G. of crystallized 3·24—3·26; of nodular 2·6—2·9. Lustre a little shining to dull. Color ochre-yellow; streak yellow, shining. Opaque.

Var., Comp.—(1) *Crystallised; Jarosite*, which occurs also fibrous and granular; G.=3·256, fr. Spain; 3·244, fr. Maryland, Breith. (2) *Concretionary*, the ordinary form of the Norway and Bohemian mineral, and the *moronolite* of Orange Co., N. Y.; G.=2·62 (moronolite)—2·79.

O. ratio for $\dot{R}$, $\dddot{\bar{R}}$, $\dddot{S}$, $\dot{H}$=1 : 12 : 15 : 9, Ramm.; $(\dot{K}, \dot{Na})\dddot{S}+4\dddot{\bar{F}}e\dddot{S}+9\dot{H}$, Ramm. For jarosite, Ferber deduces 1 : 15 : 18 : 10, differing mainly in a little less of alkali. Richter's analysis of it was imperfect. It is isomorphous with alunite, which would suggest the ratio 1 : 9 : 12 : 6, which also differs mainly in the proportion of protoxyd. Analyses: 1, Rammelsberg (l. c.); 2, Scheerer (Pogg., xlv. 188); 3, J. H. Ferber (B. H. Ztg., xxiii. 10); 4, Tyler (Am. J. Sci., II. xli. 212):

	$\dddot{S}$	$\dddot{\bar{F}}e$	$\dot{Na}$	$\dot{K}$	$\dot{H}$
1. Kolosoruk, *Gelbeis.*	32·11	46·73	—	7·88	13·56, $\dot{Ca}$ 0·64=100·92 Rammelsberg.
2. Modum, "	32·45	49·63	5·20	—	13·11=100·39 Scheerer.
3. Spain, *Jarosite*	31·76	49·24	0·80	5·90	11·35, $\dddot{\bar{A}}l$ 1·25=100·38 Ferber.
4.[a] Monroe, N. Y., *Moron.*	34·17	46·89	3·81		13·18, $\dddot{\bar{A}}l$ 0·83, $\dot{Ca}$ 1·10=99·98 Tyler.

[a] Result after subtracting 1·88 "hygr. water" and 11·17 insol.

Pyr., etc.—Nearly as for coquimbite.

Obs.—The original of this species was from Luschitz, between Kolosoruk and Bilin, Bohemia, in brown coal; and later from Modum, Norway, in alum slate.

The jarosite was from Barranco Jaroso, in the Sierra Almagrera, Spain, on limonite; also, according to Breithaupt (B. H. Ztg., xxv. 149), from Maryland, of granular form, with quartz and a magnetite altered to hematite; Mexico; Saxony, Thekla mine, near Hauptmanngrün in Voigtland, in small crystals on turgite (hydrohematite) and limonite; Erzgebirge, near Schwarzenberg, at the Frisch Glück mine. It is isomorphous with beudantite.

Moronolite is from Monroe, N. Y., where it occurs on gneiss. It contains less alkali than is required for the formula. Named *moronolite* from μωρον, *mulberry*, alluding to a resemblance to the mulberry calculus.

Erusibite Shepard (Rep. Mt. Pisgah Copper Mine, N. Haven, 1859; Am. J. Sci., II. xxviii. 129, 1859) is a "rusty insoluble ferric sulphate" of undetermined nature. His *copperasine* (ib.) is announced as a "hydrous cuprous and ferric sulphate," from the same place. His *leucanterite* (ib.) is an efflorescence on the copperasine. These are names without descriptions.

692. CARPHOSIDERITE. Karphosiderit *Breith.*, Schw. J., l. 314, 1827.

In reniform masses, and incrustations.

H.=4—4·5. G.=2·49—2·5, Breith.; 2·728, Pisani. Lustre resinous Color pale and deep straw-yellow. Streak yellowish. Feel greasy.

Comp.—O. ratio for $\overline{\text{Fe}}$, $\dddot{\text{S}}$, $\dot{\text{H}}$=1 : 1·28 : 1·08; if a fourth of the water is basic $(\frac{1}{3}\overline{\text{Fe}}+\frac{1}{3}\dot{\text{H}})^3$ $\dddot{\text{S}}+2\dot{\text{H}}$=Sulphuric acid 31·4, sesquioxyd of iron 50·2, water 18·4=100. Analyses: 1, Pisani (C. R. lviii. 242, J. pr. Ch., xcii. 376); 2, same, after removing impurities:

	$\dddot{\text{S}}$	$\overline{\text{Fe}}$	$\overline{\text{Mn}}$	$\dot{\text{H}}$	Sand	Gypsum
1.	25·52	40·00	*tr.*	10·67	14·78	9·08=100.
2.	31·82	49·88	—	18·30	—	—=100.

Supposed by Harkort (l. c.), after blowpipe trials, to be a hydrous phosphate; but shown by Pisani's analysis of an original specimen to be a sulphate.

Pyr., etc.—B.B. nearly like copiapite. Insoluble in water.

Obs.—Occurs in fissures in mica slate, and was first distinguished by Breithaupt among some specimens which he says were from Labrador. Pisani's specimens were from the Kōlburg collection in Paris, and were labelled Greenland, most probably the true locality.

The name alludes to the color, and is from *κάρφος*, *straw*, *σίδηρος*, *iron*.

693. PARALUMINITE. Paraluminit *Steinberg*, J. pr. Ch., xxxii. 495, 1844.

Massive, and like aluminite. White to pale yellow.

Comp.—$\overline{\text{Al}}^2\dddot{\text{S}}+15\dot{\text{H}}$=Sulphuric acid 14·4, alumina 37·0, water 48·6=100.

Analyses: 1–6, Schmid, Martens, Marchand, Wolff, Backs (J. pr. Ch., xxxii. xxxiii.); 7, Dieck (ZS. nat. Ver. Halle, xiii. 265); 8, Berthier (Mem., 1839, 288):

		$\dddot{\text{S}}$	$\overline{\text{Al}}$	$\dot{\text{H}}$
1.	South of Halle	14·54	36·17	49·03=99·74 Schmid.
2.	" "	14·04	35·96	50·00=100 Martens.
3.	" "	17·0	36·0	47·2=100·2 Marchand.
4.	" "	12·44	38·81	47·07, $\dot{\text{Ca}}\ddot{\text{C}}$ 1·68=100 Wolff.
5.	" "	12·22	37·71	49·18, $\dot{\text{Ca}}\ddot{\text{C}}$ 1·00=100·11 Backs.
6.	" "	11·45	39·50	48·80=99·75 Marchand.
7.	" "	15·56	36·54	46·89=98·99 Dieck.
8.	Huelgoet	13·37	43·00	43·63=100 Berthier.

Another analysis of the mineral from Presslers mountain, near Halle, afforded Geist (ZS. Nat. Ver. Halle, xiii. 268) $\dddot{\text{S}}$ 22·18, $\overline{\text{Al}}$ 39·86, $\dot{\text{H}}$ 34·91 by loss, $\dddot{\text{Si}}$ 1·92, $\overline{\text{Fe}}$ 0·40, $\dot{\text{Ca}}$ 0·50, $\dot{\text{Mg}}$ 0·03. For a similar mineral from Bernon, near Epernay, France, Lassaigne obtained (Ann. Ch. Phys., xxix. 98) $\dddot{\text{S}}$ 20·06, $\overline{\text{Al}}$ 39·70, $\dot{\text{H}}$ 39·94, gypsum 0·30=100.

Pyr., etc.—Nearly as for aluminite.

Obs.—Similar in its modes of occurrence to aluminite. Found in Presslers mountain (anal. 7) and elsewhere, near Halle, and Huelgoet in Brittany.

694. PISSOPHANITE. Pissophan *Breith.*, Char., 101, 1832. Garnsdorfite.

Amorphous, or stalactitic, somewhat pitch-like in appearance.

H.=1·5. G.=1·93—1·98. Lustre vitreous. Color pistachio-, asparagus-, or olive-green. Transparent. Very fragile. Fracture conchoidal.

Comp.—Erdmann (Schw. J., lxii. 104) obtained:

	$\dddot{\mathrm{S}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{H}}$		
1. *Green*	12·70	85·15	9·74	41·69,	gangue and loss	0·72=100.
2. "	12·49	35·30	9·80	41·70	"	0·71=100.
3. *Yellow*	11·90	6·80	40·06	40·13	"	1·11=100.

Probably not a simple mineral. Perhaps Nos. 1 and 2, $\overline{\mathrm{R}}^3\dddot{\mathrm{S}}+15\dot{\mathrm{H}}$, and No. 3, $\overline{\mathrm{R}}^3\dddot{\mathrm{S}}+15\dot{\mathrm{H}}$. The relation in the former is more exactly $\overline{\mathrm{R}}^6\dddot{\mathrm{S}}^3+30\dot{\mathrm{H}}$.

Pyr., etc.—For the most part insoluble in water. Easily soluble in muriatic acid. B.B becomes black. In a glass tube gives alkaline water.

Obs.—Occurs at Garnsdorf, near Saalfeld, and at Reichenbach, Saxony, on alum slate.

Named from πίσσα, *pitch*, and φανός, *appearance*.

695. FELSOBANYITE. Felsöbanyt *Haid.*, Ber. Ak. Wien, 1852, xii. 183, 1854.

Orthorhombic. Massive, and in concretions, grouped or single, consisting of scales, which are hexagonal, and have two angles of 112°. Cleavage perfect. Optically biaxial.

H.=1·5. G.=2·33. Lustre of cleavage-face pearly. Color snow-white, surface often yellowish. Translucent to subtransparent.

Comp.—$\overline{\mathrm{Al}}^2\dddot{\mathrm{S}}+10\dot{\mathrm{H}}$=Sulphuric acid 17·2, alumina 44·1, water 38·7=100. **Analysis**: v. Hauer (Ber. Ak. Wien, xii. 188):

(½) $\dddot{\mathrm{S}}$ 16·47 $\overline{\mathrm{Al}}$ 45·53 $\dot{\mathrm{H}}$ 37·27=99·27 Hau.

Pyr., etc.—Nearly as for aluminite.

Obs.—From Kapnik near Felsöbanya in Hungary, the concretions sometimes grouped on barite.

696. GLOCKERITE. Vitriolocker *Berz.*, Afh., v. 157, 1816. Fer sous-sulfaté terreux *Berz.*, N. Min. Syst., 1819. Vitriol Ochre. Pittizite *Beud.*, Tr., 447, 1824. Glockerit *Naum.*, Min 254, 1855.

Massive, sparry or earthy. Stalactitic.

Lustre resinous or earthy. Color brown to ochre-yellow, also brownish black to pitch-black; dull green. Streak ochre-yellow to brown. Opaque to subtranslucent. Fracture shining to earthy.

Comp., Var.—$\overline{\mathrm{Fe}}^2\dddot{\mathrm{S}}+6\dot{\mathrm{H}}$, Berzelius, for a brown to ochre-yellow variety, occurring with botryogen at Fahlun, containing according to him, Sulphuric acid 15·9, sesquioxyd of iron 62·4, water 21·7=100.

The same for a stalactitic variety from Obergrund, near Zuckmantel, the stalactites of which are sometimes 2 feet long, brown to pitch-black, yellowish-brown, and dark green in color, with yellowish-brown to ochre-yellow streak, shining lustre to earthy, and insoluble in water. It is the *Glockerite* of Naumann, who cites Hochstetter's analysis, $\dddot{\mathrm{S}}$ 15·19, $\overline{\mathrm{Fe}}$ 64·34, $\dot{\mathrm{H}}$ 20·7, agreeing closely with that by Berzelius.

Jordan obtained for a compact and earthy vitriol ochre from Rammelsberg mine near Goslar (J pr Ch., ix. 95), and Scheerer for another from Modum, Norway (Pogg., xlv. 188):

	$\dddot{\mathrm{S}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{H}}$
1. Goslar, *compact*	13·59	63·85	18·46, $\dot{\mathrm{Z}}$n 1·23, $\dot{\mathrm{C}}$u 0·87, gangue 2·00=100 Jordan.
2. " *earthy*	9·80	68·75	15·52, $\dot{\mathrm{Z}}$n 1·29 $\dot{\mathrm{C}}$u 0·50, gangue 4·14=100 Jordan.
3. Modum, *brown*	6·00	80·78	18·57=100 Scheerer.

Pyr., etc.—Nearly as for copiapite.

Obs.—A result of the alteration of pyrite or marcasite.

Glockerite was named after the mineralogist E. F. Glocker. Pitticite is the name of pitchy iron ore, q. v.

697. LAMPROPHANITE. Lamprophan *Igelström*, Œfv. Ak. Stockh., 1866, 93.

In thin cleavable folia.

H.=3. G.=3·07. Lustre pearly. Color and streak white.

Comp.—An analysis afforded Igelström (l. c.):

$\dddot{S}$	$\dot{P}b$	$\dot{M}n$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$, $\dot{K}$	$\dot{H}$
11·17	28·00	7·90	5·26	24·65	14·02	8·35=99·35.

Pyr., etc.—Yields water. With soda on charcoal yields metallic lead and a hepatic mass. Not wholly soluble in acids.

Obs.—From Longban in Wermland, Sweden. Named in allusion to the lustre from λαμπρός, *shining*.

---

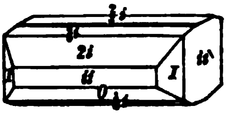
700. LINARITE. Linarite *Brooke*, Ann. Phil., II. iv. 117, 1822. Cupreous Sulphate of Lead, Cupreous Anglesite. Bleilasur, Kupferbleispath, *Germ.*

Monoclinic. *C*=77° 27′; *I* ∧ *I*, over *i-i*,=61° 36′, *O* ∧ 1-*ì*=141° 5′, *a* : *b* : *c*=0·48134 : 1 : 0·5819. Observed planes: *O*; vertical, *i-i*, *I*, *i-ì*, *i*-2; hemidomes, ⅛-*i*, ⅔-*i*, ⅚-*i*, 1-*i*, $\frac{4}{3}$-*i*, 2-*i*, $\frac{5}{2}$-*i*, 7-*i*; −1-*i*; clinodomes, 1-*ì*, ½-*ì*; hemipyramids, 2, 2-2, $\frac{4}{3}$-$\frac{4}{3}$, $\frac{8}{7}$-8. Fig. 544. Plane *i-ì* often wanting.

O ∧ *i-i*=102° 33′
O ∧ 1-*i*=152 19
O ∧ −1-*i*=156 57½
O ∧ ⅔-*i*=161 23½
O ∧ 2-*i*=130 5
O ∧ ⅛-*i*=176 36
O ∧ ⅚-*i*=156 48
O ∧ *I*=96 23

O ∧ *i-ì*=90°
O ∧ ½-*ì*=158 1
i-i ∧ 1-*i*=105 8
i-i ∧ −1-*i*=125 35½
i-i ∧ 2-*i*=127 22
i-2 ∧ *i*-2, ov. *i-i*,=100 1
I ∧ 2-2=137 1
I ∧ 2=159 9

544



Twins: composition-face *i-i* common; *O* ∧ *O′*=154° 54′. Cleavage: *i-i* very perfect; *O* less so.

H.=2·5. G. = 5·3 – 5·45. Lustre vitreous or adamantine. Color deep azure-blue. Streak pale blue. Translucent. Fracture conchoidal. Brittle.

Comp.—O. ratio for $\dot{C}u$, $\dot{P}b$, $\dddot{S}$, $\dot{H}$=1 : 1 : 3 : 1, whence $\dot{P}b\,\dddot{S}+\dot{C}u\,\dot{H}$; or, if $\dot{H}$ be basic, for base and acid 1 : 1=$(\frac{1}{3}\dot{C}u+\frac{1}{3}\dot{P}b+\frac{1}{3}\dot{H})^3\dddot{S}$. It seems to be an objection to the first formula that there is no near isomorphism with any sulphate of lead, while there is with cyanosite or sulphate of copper.

Analyses: 1, Brooke (l. c.); 2, Thomson (Phil. Mag., III. xvii. 402); 3, v. Kobell (J. pr. Ch., lxxxiii. 454):

	$\dot{P}b\dddot{S}$	$\dot{C}u$	$\dot{H}$
1. Wanlockhead	75·4	18·0	4·7=98·1 Brooke.
2. "	74·8	19·7	5·5=100 Thomson; G.=5·2137.
3. Kadainski	76·41	17·43	6·16, Cl *tr.*=100 Kobell.

Pyr., etc.—In the closed tube yields water and loses its blue color. B.B. on charcoal fuses easily to a pearl, and in R.F. is reduced to a metallic globule which by continued treatment coats the coal with oxyd of lead, and if fused boric acid is added yields a pure globule of copper. With soda gives the reaction for sulphuric acid. Decomposed with nitric acid, leaving a white residue of sulphate of lead.

Obs.—Formerly found at Leadhills. Occurs at Roughten Gill, Red Gill, and near Keswick, in Cumberland, in crystals sometimes an inch long; near Schneeberg, rare; in Dillenburg, at the mines Aurora and Thomas; Nassau on the Lahn; at Retzbanya; at the Kadainski mine in

Nertschinsk; and in the vicinity of Beresof in the Ural; and supposed formerly to be found a Linares in Spain, whence the name.

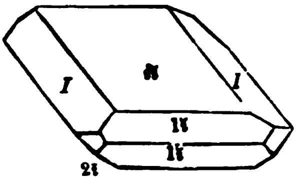
Alt.—Linarite occurs altered to cerussite, a change like that of anglesite to cerussite.

For recent obs. on cryst., B. & M., Min.; Greg & Lettsom, Min., 395, 1858; Kokscharof, Min. Russl., iv. 139, v. 106; Hessenberg, Min. Not., No. vii., from whom the above angles are taken: K. Peters, Ber. Ak. Wien, xliv. 168.

701. BROCHANTITE. Brochantite (fr. Katharinenb.) *Levy*, Ann. Phil., II. viii. 241, 1824 Konigine (fr. Russia) *Levy*, ib., xi. 194, 1826. Brongnartine (fr. Mexico) *Huot*, Min., i. 331, 1841. Krisuvigit (fr. Iceland) *Forchhammer*, Skand. Nat. Stockh., 1842, Arsb. 1843, 192 Waringtonite (fr. Cornwall) *Maskelyne*, Ch. News, x. 263, 1864, Phil. Mag., IV. xxix. 475.

Orthorhombic. *I* ∧ *I*=104° 32′, *O* ∧ 2-ī=147° 49′; *a* : *b* : *c*=0·31471 : 1 : 1·2923. Observed planes: vertical, *I*, i-ĭ, i-2̆; domes, 1-ĭ, 2-ī. Fig. 545; also prisms made of *I* and i-2̆, and dome 1-ĭ without i-ĭ, the form resembling f. 542, p. 657, excepting the absence of *O*, this plane not having been observed.

545



i-2̆ ∧ i-2̆, ov. i-ĭ,=114° 16′
1-ĭ ∧ 1-ĭ=152 37
2-ī ∧ 2-ī, ov. *O*,=115 38
i-ĭ ∧ i-2̆=147 8
i-ĭ ∧ *I*=127 44
i-ĭ ∧ 1-ĭ=103 41

Also in groups of acicular crystals and drusy crusts. Cleavage: i-ĭ very perfect; *I* in traces. Also massive; reniform with a columnar structure.

H.=3·5—4. G.=3·78—3·87, Magnus; 3·9069, G. Rose. Lustre vitreous; a little pearly on the cleavage-face i-ĭ. Color emerald-green, blackish-green. Streak paler green. Transparent—translucent.

Var.—1. *Ordinary Brochantite.* The analyses vary considerably, as shown below. The crystals are vertically striated.

2. *Waringtonite.* Essentially brochantite in composition, but occurring in non-striated crystals in form like a doubly curving wedge, of paler green color than ordinary brochantite, with G.= 3·39—3·47, and H.=3—3·5.

Comp.—O. ratio for $\dot{C}u$, $\bar{S}$, $\dot{H}$=7 : 6 : 5; $\dot{C}u\bar{S}+2\frac{1}{2}\dot{C}u\dot{H}$; or perhaps $2\dot{C}u^3\bar{S}+\dot{C}u\dot{H}+4\dot{H}$; =Sulphuric acid 19·9, protoxyd of copper 69·0, water 11·1=100. Some analyses correspond to the O. ratio 4 : 3 : 3; and Field's to 4 : 3 : 4, the ratio of langite. Analyses: 1, 2, Magnus (Pogg., xiv. 141); 3, Forchhammer (J. pr. Ch., xxx. 396); 4, Berthier (Ann. Ch. Phys., l. 360); 5, H. Risse (Pogg., cv. 614); 6, Pisani (C. R., lix. 912); 7, Warrington (J. Ch. Soc., II. iii. 85); 8, Maskelyne (Phil. Mag., IV. xxix. 475); 9, Tschermak (Ber. Ak. Wien, li. 131); 10, Field (Phil. Mag., IV. xxiv. 123); 11, v. Kobell (Ber. Ak. München, 1865, ii. 70); 12, Domeyko (Ann. d. M. VI. v. 460):

	$\bar{S}$	$\dot{C}u$	$\dot{Z}n$	$\dot{P}b$	$\dot{H}$
1. Retzbanya	17·132	62·626	8·181	0·030	11·887=99·856 Magnus.

11. "	19·71	68·87	——	——	[11·42]=100 Kobell.
12. "	15·8	68·5	——	——	13·5, gangue 2·4=100 2 Domeyko

[a] With Fe^2O^3. [b] 1·04 per cent. water lost below 260° C.

The Mexican corresponds to $\dot{C}u^4\dddot{S}+4\dot{H}$, and is the *Brongnartine* of Huot.

Rivot found in crystals of brochantite of a fine green color, which afforded a slight efforvescence with acids, $\dddot{S}$ 19·4, $\dot{C}u$ 62·9, $\dot{H}$ 13·5, with $\ddot{C}$ 1·2, $\dot{H}$ 1·2=98·2. The mineral had undergone partial alteration as shown by the 6·2 p. c. of carbonate of copper present (Ann. d. M., V. iii. 740).

Pyr., etc.—Yields water, and at a higher temperature sulphuric acid, in the closed tube, and becomes black. B.B. fuses, and on charcoal affords metallic copper. With soda gives the reaction for sulphuric acid.

Obs.—Occurs in small but well defined crystals, with malachite and native copper, at Gumeschevsk and Nischne-Tagilsk in the Ural; the Königine (or *Königite*) was from Gumeschevsk; in small brilliant crystals with malachite in a quartzose rock near Roughten Gill, in Cumberland; in Cornwall (in part *waringtonite*), and sometimes with crystals of brochantite on the so-called waringtonite; at Retzbanya; in Nassau, with chalcopyrite; in small beds at Krisuvig in Iceland (*krisuvigite*); in Mexico (*brongnartine*); in Chili at Andacollo (anal. 10); in Australia (brought from Sidney, N.S.W., anal. 9).

Named after Brochant de Villiers; waringtonite is from Warington W. Smyth.

On cryst., G. Rose, Reis. Ural, i. 267; Kokscharof, Min. Russl., iii. 260. The above angles are from Kokscharof. G. Rose found $I \wedge I$=104° 10′, and 1-ĭ ∧ 1-ĭ=151° 52′. Fig. 545 is from Levy. Kokscharof's figures have not the plane 2-ĭ, and several are without i-ĭ.

Artif.—Formed in a bright green powder by Field (Phil. Mag., IV. xxiv. 123) by adding to a strong solution of sulphate of copper a small quantity of caustic potash, boiling, filtering, and washing till all the sulphate of copper is removed; analysis after drying at 100° C. afforded $\dddot{S}$ 16·98, $\dot{C}u$ 67·51, $\dot{H}$ [15·51]=100, giving the O. ratio 4 : 3 : 4. See further under LANGITE.

702. LANGITE. A new British mineral *N. S. Maskelyne*, Phil. Mag., IV. xxvii. 306, 1864. Langite *Maskelyne*, Pisani, C. R., lix. 633, 1864, Maskelyne, Phil. Mag., IV. xxix. 473, 1865. Devilline *Pisani*, C. R., 813, 1864=Lyellite *Maskelyne*, Ch. News, x. 263, 1864.

Orthorhombic. $I \wedge I$=123° 44′; $O \wedge$ 1-ĭ=147° 36′; $a : b : c$=0·6346 : 1 : 1·8702. $I \wedge$ i-ĭ=118° 8′, $O \wedge$ 2-ĭ=128° 14′. Cleavage: apparently O and i-ĭ. Crystals small and short; simple forms not observed. Twins: composition-face I, and forms like those of aragonite. Also in fibro-lamellar and concretionary crusts, with earthy surface.

H.=2·5–3. G.=3·48–3·50, Maskelyne. Lustre of crystals vitreous; of crusts somewhat silky. Color fine blue to greenish-blue; through i-ī blue; through i-ĭ greenish-blue; through O paler greenish-blue. Translucent.

Comp.—O. ratio for $\dot{R}$, $\dddot{S}$, $\dot{H}$=4 : 3 : 4, Pisani; 4 : 3 : 5, Maskelyne. The former gives the formula $\dot{C}u\dddot{S}+3\dot{C}u\dot{H}+\dot{H}$=Sulphuric acid 17·0, oxyd of copper 67·7, water 15·3=100. The latter corresponds to Sulphuric acid 16·4, oxyd of copper 65·1, water 18·5=100. The ratio 4 : 3 : 4 gives also the formula $\dot{C}u^3\dddot{S}+\dot{C}u\dot{H}+3\dot{H}$.

Analyses: 1, Maskelyne (l. c.); 2, Pisani (l. c.); 3–5, A. H. Church and R. Warrington (J. Ch. Soc., II. iii. 87); 6, Tschermak (Ber. Ak. Wien, li. i. 127):

	$\dddot{S}$	$\dot{C}u$	$\dot{C}a$	$\dot{H}$
1. Cornwall	16·42	65·82	——	18·32=100·56 Maskelyne.
2. "	16·77	65·92	0 83	16·19, $\dot{M}g$ 0·29=100 Pisani.
3. "	16·79	67·48	——	15·73=100 Church.
4. "	16·72	67·31	——	16·25=100·28 Warrington.
5. "	16·88	67·88	——	15·53=100·29 Warrington.
6. "	16·2	68·1	0·5	[15·2]=100 Tschermak.

The *devilline* (or *lyellite*), which includes the incrusting variety, is, as Tschermak has shown (l. c.), langite mixed with gypsum, which is apparent in scales. His analysis above was made on the devilline after separating 18 p. c. of gypsum; and he stated that Pisani's analysis of the same (l. c.) indicates the presence of 24 p. c. For an analysis of the *lyellite* by Church see J. Ch. Soc., II. iii. 83.

Pyr., etc.—B.B. on charcoal yields water, acid fumes, and metallic copper. Heated it passes through (1) a bright green color, losing 1 equivalent of water, and then having the O. ratio (4 : 3 : 4) of some brochantite; (2) various tints of olive-green; and (3) becomes black. It has finally a strongly acid reaction.

Obs.—Found in argillaceous schist (killas) in Cornwall, in minute twinned crystals; also as a blue crust, partly earthy. It is associated sometimes with connellite.

Named *langite* after Dr. V. v. Lang, formerly of the British Museum.

The analyses of so-called brochantite by Berthier of a Mexican specimen, and Field of a Chilian, as well as of the artificial mineral, have the same composition assigned by Pisani and Church tc the *langite;* and there is yet some uncertainty as to the true limits between the two species. The specimens had the *green* color of brochantite.

703. CYANOTRICHITE. Kupfersammeterz, Kupfersammterz, *Wern.*, Karsten's Tab., 62, 1808. Velvet Copper Ore *Jameson*, Min., iii. 153, 1816. Sammeterz *Breith.*, Char., 168, 1823, 320, 1832. Cuivre velouté *Fr.* Cyanotrichit *Glocker*, Grundr., 587, 1839. Lettsomite *Percy*, Phil. Mag., xxxvi. 103, 1850.

Occurs in druses of short capillary crystals, and having an appearance like velvet; sometimes in spherical globules.

Color clear smalt-blue, sometimes passing into sky-blue. Lustre pearly.

Comp.—O. ratio for $\dot{C}u$, $\dddot{\overline{A}}l$, $\dddot{\overline{S}}$, $\dot{H}$, from mean of analyses, 9·03 : 5·48 : 8·85 : 20·50. Taking it at 9 : 6 : 9 : 21, the formula may be 3 $\dot{C}u^3\dddot{\overline{S}}+2\dddot{\overline{A}}l\dot{H}^3+15\dot{H}$; or 3 $\dot{C}u\dddot{\overline{S}}+2\dot{C}u^3\dot{H}^3+2\dddot{\overline{A}}l\dot{H}^3+9\dot{H}=3\dot{C}u\dddot{\overline{S}}+4(\tfrac{1}{2}\dot{C}u^3+\tfrac{1}{2}\dddot{\overline{A}}l)\dot{H}^3+9\dot{H}$. Needs further investigation. Analyses: J. Percy (l. c.):

$\dddot{\overline{S}}$	$\dddot{\overline{A}}l$	$\dddot{\overline{F}}e$	$\dot{C}u$	$\dot{H}$
15·39	11·70		43·16	23·06=98·30.
14·12	11·06	1·18	46·59	23·06, insol. 2·35=98·36.

Obs.—Occurs sparingly at Moldawa in the Bannat, coating the cavities of an earthy hydrated oxyd of iron, along with a white amorphous sulphate of alumina.

Named *Cyanotrichite* from κύανος, *blue*, and θρίξ, *hair;* and *Lettsomite* after the English mineralogist, W. G. Lettsom.

704. **Woodwardite** *Church*, Ch. News, xiii. 85, 113, 1866, J. Chem. Soc., II. iv. 130. Probably an impure uncrystallized variety of the above, mixed with hydrate of alumina. Occurs in Cornwall, in minute botryoidal concretions, of a rich turquois-blue to greenish-blue color, translucent to almost transparent; G.=2·38. Analyses: 1–3, Church and Warrington (l. c.); 4, Pisani (C R., lxv. 1142):

		$\dddot{\overline{S}}$	$\dddot{\overline{A}}l$	$\dot{C}u$	$\dot{H}$
1.	Cornwall	13·95	17·97	48·34	18·48=98·74 Church.
2.	"	13·04	18·64	48·67	[19·65]=100 Warrington.
3.	"	12·54	17·93	46·80	[22·73]=100 Warrington.
4.	"	11·7	13·4	46·8	[26·9], $\dddot{S}i$ 1·2=100 Pisani.

Church and Warrington also found traces of silica, lime, magnesia, and phosphoric acid, which were undetermined. The mean of the first 3 analyses affords the O. ratio for $\dot{C}u$, $\dddot{\overline{A}}l$, $\dddot{\overline{S}}$, $\dot{H}=11:9{\cdot}6:9:23$; equivalent to 3 $\dot{C}u^3\dddot{\overline{S}}$, 2 $\dot{C}u\dot{H}$, 3 $\dddot{\overline{A}}l\dot{H}^3$, 12 $\dot{H}$; or 3 $\dot{C}u\dddot{\overline{S}}$, 8 $\dot{C}u\dot{H}$, 3 $\dddot{\overline{A}}l\dot{H}^3$, 6 $\dot{H}$. No. 4, by Pisani, gives about 12 : 9 for the $\dot{C}u$ and $\dot{H}$, the ratio in langite, and he makes the mineral impure *langite.* He analyzed (l. c.) another similar material from Cornwall (received from Mr. Talling), of a clear green color, and obtained $\dddot{\overline{S}}$ 4·7, $\dddot{\overline{A}}l$ 33·8, $\dot{C}u$ 17·4, $\dot{H}$ 38·7, $\dddot{S}i$ 6·7=100·5; showing a mixture of the copper sulphate with a hydrous silicate of alumina as well as hydrate; and this he considers as proving that woodwardite is only a mixture.

The mineral is soluble with scarcely any residue in diluted acids. Named after Dr. S. P. Woodward.

705. JOHANNITE. Uranvitriol *John*, Ch. Unters., V. 254, 1821. Johannit *Haid.*, Abhandl., böhm. Ges. Prag, 1830. Sulphate of Uranium. Sulfate vert d'urane *Beud.*

Monoclinic. $C=85°\ 40'$, $I\wedge I=69°$. Crystals flattened, and from one to three lines in length; arranged in concentric druses or reniform masses.

H.=2–2·5. G.=3·19. Lustre vitreous. Color beautiful emerald-green, sometimes passing into apple-green. Streak paler. Transparent—

translucent; sometimes opaque. Soluble in water. Taste bitter rather than astringent.

Comp.—O. ratio for bases and acid 1 : 1, whence the formula $(\dot{U}^3, \dddot{\bar{U}})\dddot{S}+\frac{1}{6}\dot{C}u^3\dddot{S}+1\frac{1}{6}\dot{H}$, or $(\frac{5}{6}(\dot{U}^3,\dddot{\bar{U}})+\frac{1}{6}\dot{C}u^3)\dddot{S}+1\frac{1}{6}\dot{H}=$, if the uranium be all sesquioxyd, Sulphuric acid 20·8, oxyd of uranium 66·1, oxyd of copper 6·9, water 6·2=100. Analysis by Lindacker (mean of two trials, Vogl's Min. Joach., 1857):

$\dddot{S}$ 20·02 $\dot{U}, \dddot{\bar{U}}$ 67·72 $\dot{C}u$ 5·99 $\dot{F}e$ 0·20 $\dot{H}$ 5·59=99·52.

Pyr., etc.—In a glass tube at a low heat does not change; highly heated gives off water and sulphurous acid, and becomes brown and finally black. B.B. on charcoal gives sulphur fumes and a scoria of black color and dull green streak. With salt of phosphorus reacts for copper and uranium. Somewhat soluble in water. Solution precipitated chestnut-brown by prussiate of potash, yellowish-green by alkalies, and in brown flocks by an infusion of nutgalls.

Obs.—Discovered by John near Joachimsthal in Bohemia, after whom the species is named. Found also at Johanngeorgenstadt. Reported from the Middletown feldspar quarry by Shepard.

---

706. URANOCHALCITE. Urangrün *Hartmann.* Uranochalzit *Breith.*, Handb., 173, 1841.

In small nodular crusts and velvety druses, consisting of acicular crystals.

H.=2—2½. Color fine grass-green to apple-green; streak apple-green.

Comp.—$(\frac{2}{3}(\dot{U}^3, \dddot{\bar{U}})+\frac{1}{3}\dot{C}a^3)\dddot{S}+\frac{1}{3}\dot{C}u\dddot{S}+9\dot{H}=$, if the uranium be taken as all sesquioxyd, Sulphuric acid 21·1, oxyd of uranium 33·5, oxyd of copper 7·0, lime 9·8, water 28·5=100. Analysis Lindacker (Vogl's Min. Joach., 1857):

$\dddot{S}$	$\dot{U}\,\dddot{\bar{U}}$	$\dot{F}e$	$\dot{C}u$	$\dot{C}a$	$\dot{H}$
($\frac{2}{3}$) 20·03	36·14	0·14	6·55	10·10	27·16=100·12.

Obs.—From Joachimsthal in Bohemia.

707. MEDJIDITE. *J. L. Smith*, Am. J. Sci., II. v. 337, 1848. Sulphate of Uranium & Lime.

Massive, with an imperfectly crystalline structure.

H.=2·5. Lustre vitreous in the fracture. Color dark amber. Transparent.

Comp.—Perhaps $\dddot{\bar{U}}\dddot{S}+\dot{C}a\dddot{S}+15\dot{H}$, according to some qualitative trials by Smith; but as probably $\dddot{\bar{U}}\dddot{S}+\dot{C}a^3\dddot{S}+15\dot{H}=(\frac{1}{2}\dddot{\bar{U}}+\frac{1}{2}\dot{C}a^3)\dddot{S}+7\frac{1}{2}\dot{H}$, and thus approaching uranochalcite.

Pyr., etc.—In a matrass easily yields water. At redness blackens, being converted into oxyd of uranium and sulphate of lime. With salt of phosphorus a green bead. Dissolves readily in dilute muriatic acid.

Obs.—Occurs near Adrianople, Turkey, on pitchblende, associated with liebigite, in some places with crystals of sulphate of lime; also at Joachimsthal, with liebigite on uranium ore. Externally often dull from loss of water.

It was named after the Turkish sultan Abdul Medjid.

708. ZIPPEITE. Basisches schwefelsaures Uranoxyd (verwitterter Uran-Vitriol) *J. F. John* Unters., v. 1821, Jahrb. Min. 1845, 299. Uranblüthe *Zippe*, Verh. Ges. Böhm. Prag, 1824. Zippeit *Haid.*, Handb., 510, 1845.

In delicate needles; acicular rosettes; warty crusts.

H.=3. Color fine sulphur-yellow, lemon-yellow, orange-yellow.

Comp.—Hydrous sulphate of sesquioxyd of uranium, with or without oxyd of copper, and lemon- to orange-yellow when without. Analyses by Lindacker (Vogl's Min. Joach.):

	$\dddot{S}$	$\bar{U}$	$\bar{F}e$	$\dot{C}u$	$\dot{C}a$	$\dot{H}$
1. *With no Copper*	18·06	67·86	0·17	—	0·61	17·69=99·39.
2. *Copper var.*	17·36	62·04	—	5·21	—	15·23=99·84.

Formula of the former $\bar{U}^3\dddot{S}^2+12\dot{H}$, Vogl; of the latter, $\bar{U}^3\dddot{S}^2+6\dot{H}$, with 16 p. c. copper vitriol as impurity, Ramm.; or $(\dot{C}u^3, \bar{U})^3\dddot{S}^2+8\dot{H}$, in which O. ratio of $\dot{C}u, \bar{U}=1:12$.

Pyr., etc.—In the closed tube water, and at a higher temperature sulphuric acid. With salt of phosphorus gives a yellowish-green glass in O.F., becoming emerald-green in R.F.

Obs.—From Joachimsthal.

Named after the mineralogist Prof. Zippe. John's *basic sulphate* is a *yellow* mineral, and may be either the preceding, or what Vogl calls *Uranochre.*

709. VOGLIANITE. Basic Sulphate of Uranium *Vogl*, Min. Joach., 1857. Voglianite *Dana*

In soft globular, and nodular, earthy coatings.

Color pistachio- to verdigris-green; streak pale green or apple-green.

Comp.—$4(\dot{U}^3, \bar{U})^3\dddot{S}+(\dot{C}a, \dot{C}u)\dddot{S}+10\dot{H}$, or, regarding the sulphate of copper and lime as impurity, $(\dot{U}^3, \bar{U})^3\dddot{S}+2\dot{H}$. Analyses by Lindacker (Min. Joach.):

	$\dddot{S}$	$\dot{U}\bar{U}$	$\bar{F}e$	$\dot{C}u$	$\dot{C}a$	$\dot{H}$
1. *Lime var.*	12·34	79·50	0·12	—	1·66	5·49=99·11.
2. *Copper var.*	12·13	79·69	0·36	2·24	0·05	5·25=99·72.

Obs.—From Joachimsthal in Bohemia.

710. URACONITE. Uranochre *Vogl*, Min. Joach. ? Uraconise *Beud.*, Tr., ii. 672, 1832. Uraconite *Dana.*

Amorphous, earthy, or scaly, and of a fine lemon-yellow color, or orange.

Comp.—Analyses by Lindacker (l. c.):

	$\dddot{S}$	$\bar{U}$	$\bar{F}e$	$\dot{C}u$	$\dot{C}a$	$\dot{H}$
1. *Yellow*	7·12	70·94	0·41	0·24	—	20·88=99·58.
2. *Orange*	10·16	66·05	0·86	—	2·62	20·06=99·76.

Formula deduced by Vogl for 1, $\bar{U}^3\dddot{S}+14\dot{H}$; for 2, $\frac{1}{2}\dot{C}a\dddot{S}+\bar{U}^3\dddot{S}+14\dot{H}$.

Obs.—From Joachimsthal, with other uranium ores. Uraconise of Beudant was described as yellow pulverulent ore; its composition is unknown.

---

711. MONTANITE. *F. A. Genth*, Private contribution, Jan. 19, 1868.

Incrusting; without distinct crystalline structure.

Soft and earthy. Lustre dull to waxy. Color yellowish to white. Opaque.

Comp.—$\breve{B}i\,Te+2\dot{H}$=Telluric acid 26·1, oxyd of bismuth 68·6, water 5·3=100. Analysis: Genth (l. c.):

Montana	Te 26·83	$\breve{B}i$ 66·78	$\bar{F}e$ 0·56	$\dot{P}b$ 0·39	$\dot{H}$ 5·94=100.

Pyr., etc.—Yields water in a tube when heated. B.B. gives the reactions of bismuth and tellurium. Soluble in dilute muriatic acid.

Obs.—Incrusts tetradymite, from whose alteration it had been formed, at Highland, in Montana The waxy lustre is observed when the incrustation has separated from the scales of tetradymite

712. KERSTENITE. Selenbleispath *Kersten*, Pogg., xlvi. 277, 1839. Selenigsaures Bleioxyd *Germ.* Selenite of Lead. Selenate of Lead. Kerstenite *Dana.*

In small spheres and botryoidal masses. Cleavage distinct in one direction. H.=3—4. Lustre greasy—vitreous. Color sulphur-yellow. Streak uncolored. Brittle. Fracture fibrous. According to Kersten, it consists of selenous acid and oxyd of lead, with a small proportion of copper. On coal it fuses readily to a black slag, giving off a strong selenium odor, and is finally reduced to a metallic globule. With borax it fuses and forms a yellowish-green pearl, which is of the same color on cooling. With soda on charcoal metallic lead is obtained. Occurs with selenid of antimony and lead, malachite, etc., at the Friederichsglück mine, near Hilburghausen, and at Eisfeld. May it be a *selenate*, or is it only a mixture?

7. CARBONATES.

The carbonates have a hardness not exceeding 5, and consequently will not, when pure, strike fire with a steel. The anhydrous come under the common general formula, RO, CO^2, but present three types of crystallization, a rhombohedral, with $R \wedge R$ near 105°; an orthorhombic, with $I \wedge I$ near 120°; and a monoclinic, with $I \wedge I$ near 105°. They constitute therefore a case of pleomorphism, while all, still, are approximately isomorphous. These anhydrous species have a vitreous to subpearly lustre, and are typically *spars*. The hydrous carbonates vary much in crystallization, and in some cases have a strongly pearly lustre. All effervesce in hot acids, and part of them in cold.

I. ANHYDROUS CARBONATES.

ARRANGEMENT OF THE SPECIES.

I. CALCITE GROUP. Rhombohedral; $R \wedge R$=105°—108°.

715. CALCITE	$\dot{\text{Ca}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\Theta\text{a}$
716. DOLOMITE	$(\frac{1}{2}\dot{\text{Ca}}+\frac{1}{2}\dot{\text{Mg}})\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|(\frac{1}{2}\Theta\text{a}+\frac{1}{2}\text{Mg})$
717. ANKERITE	$(\frac{1}{2}\dot{\text{Ca}}+\frac{1}{2}(\dot{\text{Mg}}, \dot{\text{Fe}}, \dot{\text{Mn}}))\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|(\frac{1}{2}\Theta\text{a}+\frac{1}{2}(\text{Mg}, \text{Fe}, \text{Mn}))$
718. MAGNESITE	$\dot{\text{Mg}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\text{Mg}$
719. MESITITE	$(\frac{2}{3}\dot{\text{Mg}}+\frac{1}{3}\dot{\text{Fe}})\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|(\frac{2}{3}\text{Mg}+\frac{1}{3}\text{Fe})$
720. PISTOMESITE	$(\frac{1}{2}\dot{\text{Mg}}+\frac{1}{2}\dot{\text{Fe}})\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|(\frac{1}{2}\text{Mg}+\frac{1}{2}\text{Fe})$
721. SIDERITE	$\dot{\text{Fe}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\text{Fe}$
722. RHODOCHROSITE	$\dot{\text{Mn}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\text{Mn}$
723. SMITHSONITE	$\dot{\text{Zn}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\text{Zn}$

II. ARAGONITE GROUP. Orthorhombic. $I \wedge I$=115°—119°.

724. ARAGONITE	$\dot{\text{Ca}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\Theta\text{a}$
725. MANGANOCALCITE	$(\frac{2}{3}\dot{\text{Mn}}+\frac{1}{3}(\dot{\text{Ca}}, \dot{\text{Mg}}))\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|(\frac{2}{3}\text{Mn}+\frac{1}{3}(\Theta\text{a}, \text{Mg}))$
726. WITHERITE	$\dot{\text{Ba}}\,\ddot{\text{C}}$	$\Theta\,\Theta\|\Theta_2\|\text{Ba}$

727. Bromlite	$(\frac{1}{2}\dot{B}a+\frac{1}{2}\dot{C}a)\ddot{C}$	$\Theta\,\Theta\|\Theta_2\|(\frac{1}{2}Ba+\frac{1}{2}Ca)$
728. Strontianite	$\dot{S}r\,\ddot{C}$	$\Theta\,\Theta\|\Theta_2\|Sr$
729. Cerussite	$\dot{P}b\,\ddot{C}$	$\Theta\,\Theta\|\Theta_2\|Pb$

III. BARYTOCALCITE GROUP. Monoclinic. $I \wedge I = 106°—107°$.

730. Barytocalcite	$(\frac{1}{2}\dot{B}a+\frac{1}{2}\dot{C}a)\ddot{C}$	$\Theta\,\Theta\|\Theta_2\|(\frac{1}{2}Ba+\frac{1}{2}Ca)$

IV. PARISITE GROUP. Carbonate containing fluorine.

731. Parisite	$(\dot{C}e, \dot{L}a, \dot{D}i)\ddot{C}+\frac{1}{2}(Ca, Ce)F$
732. Kischtimite	$6\,\dot{L}a\,\ddot{C}+Ce^2O^3+Ce^2F^3+2\,\dot{H}$

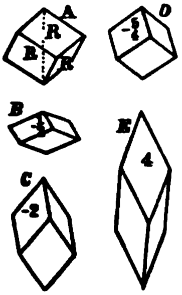
V. PHOSGENITE GROUP. Carbonate containing chlorine.

733. Phosgenite	$\dot{P}b\,\ddot{C}+Pb\,Cl$

715. CALCITE. Marmor (Marble) pt. *Plin.* Lapis calcarius. Saxum calcis (*Calx* in Latin meaning burnt lime), Kalchstein *Agric.*, De Nat. Foss., 320, Interpr., 468, 1546. Kalksten *Wall.*, Min., 1747. Spatig Kalksten, Kalkspat, *Cronst.*, Min., 18, 1758. Kalk, Kalkspath, Kalkstein, *Germ.* Calx aerata *Bergm.*, 1774, and Opusc., i. 24 1780. Calcareous Spar; Limestone; Carbonate of Lime. Chaux carbonatée *Fr.* Calcit *Haid.*, Handb., 498, 1845.

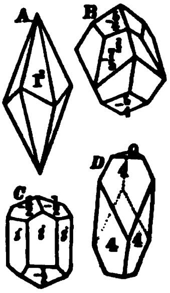
Rhombohedral. $R \wedge R$ (f. 550A, over a terminal edge)$=105°\ 5'$, $O \wedge R = 135°\ 23'$; $a=0{\cdot}8543$. Cleavage: R highly perfect.

550

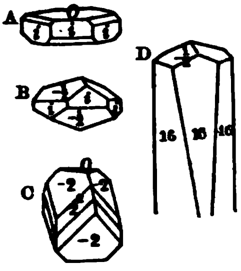


551

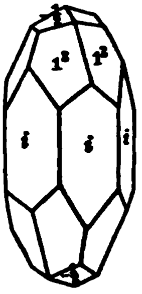
552



553



554



Observed forms: 1. *Rhombohedrons;* forms whose planes are in the same vertical zone with R (one of which, 4, is shown in f. 559, 550E, and three of the *minus* series, in −2, $-\frac{5}{4}$, $-\frac{1}{2}$, in f. 564, 550C, D, B); the *plus* rhombohedrons ranging from $\frac{1}{4}R$ (the vertical axis of which is $\frac{1}{4}$th that of R relatively to the lateral axes) to $28R$, the planes of the former nearly coincident with the basal plane o, and of the latter as nearly with those of the vertical prism; the *minus* rhombohedrons ranging from $-\frac{1}{10}$ to −14; the fundamental rhombohedron R (f. 550A) uncommon, except in combination with other planes, or as a cleavage form; $-\frac{1}{2}R$ (f. 550B, often called *nail-head* spar) corresponding to a truncation of the terminal edge of R, very common, and especially in combination (f. 552C, 553A, B, 564, 565); $-2R$ (f. 550c), called the *inverse* by Haüy, because the angle over the lateral edges is near that over the terminal of R, common; $-\frac{1}{4}R$ (f. 550d),

Rossie.

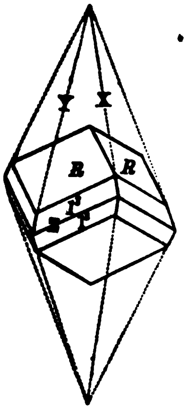
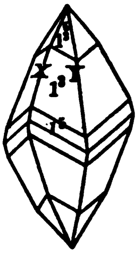
or the cuboid of Haüy, its angles being rather near those of a cube, and the acute form $4R$ (f. 550e), also common; $13R$ (f. 551) of not unfrequent occurrence; $16R$ (f. 553d).

2. Scalenohedrons. (*a*) Planes bevelling the lateral edges of R, f. 562, which, when more extended, take the form in the dotted lines of the same figure, or the complete scalenohedron; the series having the general symbol 1^n, and including all the forms in the table beyond from $1^{\frac{1}{8}}$ to 1^{13} (the 1 signifying that they are thus related to the rhombohedron $1R$, and the annexed number indicating the length of the vertical axis as compared with that of $1R$; also a *minus* series, -1^n, having the same relation to $-1R$; three of the *minus* series are combined in the illustrative figure, f. 563, and two of the *plus* in

562

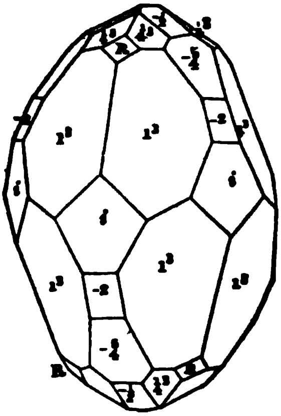


563



f. 559); scalenohedron 1^3 (f. 552A, *dog-tooth spar*) very common, both simple and in combination (the latter in f. 555 to 559, 564, 565; f. 556 a distorted form of f. 555). (*b*) Planes bevelling the lateral edges of $-2R$ (f. 553c), and having the general symbol -2^n. (*c*) Planes having the same relation to other rhombohedrons, but if referred to the fundamental rhombohedron, R, replacing its lateral or terminal angles, or terminal edges (f. 561, 564). (*d*) The last mentioned bevelling the terminal edges of R (as $\frac{1}{4}^3$ in f. 564), having the general symbol m^n, with $\frac{2}{3}\,mn-\frac{1}{3}\,m=1$ when the scalenohedron is *plus* like the R, but $\frac{2}{3}\,mn+\frac{1}{3}\,m=1$ when *minus*. (*e*) Bevelments of terminal edges of other rhombohedrons, $m'R$, having the same general symbol m^n, but with $\frac{2}{3}\,mn-\frac{1}{3}\,m=m'$, when of like signs with $m'R$, and $\frac{2}{3}\,mn+\frac{1}{3}\,m=m'$, when of unlike signs.

564



Derbyshire.

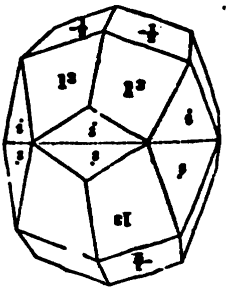
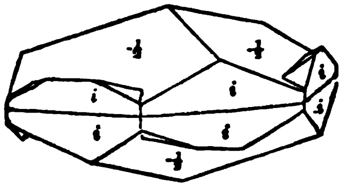
566

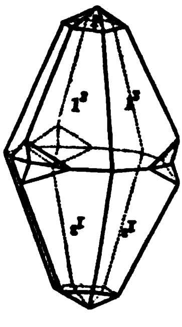


567

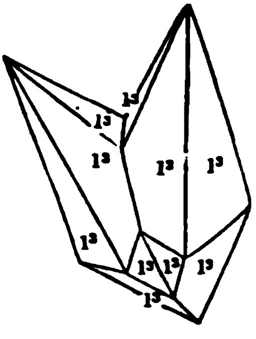


Alston-Moor.

568



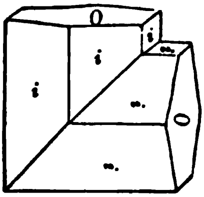
569



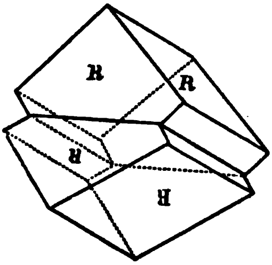
3. *Regular six-sided pyramids*; general symbol m-2, as 4-2, f. 561.

4. *Prisms*. (*a*) The regular six-sided prism i, very common, either short or long (f. 552C, 553A, B, 554, 570). (*b*) Prism i-2, only in combination and not common. (*c*) Twelve-sided prisms i-$\frac{3}{2}$, i-$\frac{4}{3}$.

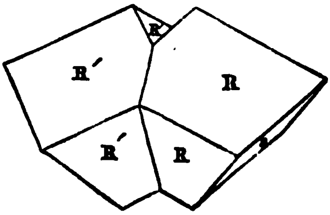
570



571



572



5. *Basal*, plane *O*, as in 552D, 553A, o, 570, far less frequent as a termination of crystals than rhombohedral and scalenohedral planes.

ANGLES OF RHOMBOHEDRONS.

R is a face of the fundamental rhombohedron 1*R*; *R'* the particular rhombohedron below in each line; *o* the basal plane:

$\frac{16}{3}$-2	121 30½	149 22	8-2	120 42	163 0

Twins: (1) Composition-face basal (or parallel to *o*), as f. 566 in the form f. 565, f. 567 in that of f. 553B, f. 568 in one similar to f. 552A. (2) C.-face R, f. 570, the vertical axes of the two forms nearly at right angles (90° 46′), since $o \wedge R = 135° 23'$; producing complex forms when highly modified. (3) C.-face $-2R$, as f. 569, in the scalenohedron 1^3, f. 552A. (4) C.-face $-\frac{1}{2}R$ (f. 571), the vertical axes of the two forms inclined to one another 127° 34′; composition often repeated, producing an alternation of thin lamellæ; and often occurring as lamellæ intersecting different forms, or cleavage rhombohedrons; common in the grains of granular limestone (Oschotz, ZS. G., vii. 5). (5) C.-face prismatic plane *i*-2. (6) C.-face plane *i* (f. 572).

Also fibrous, both coarse and fine; sometimes lamellar; often granular; from coarse to impalpable, and compact to earthy. Also stalactitic, tuberose, nodular, and other imitative forms.

H.=2·5–3·5; some earthy kinds (chalk, etc.) 1. G.=2·508–2·778; pure crystals, 2·7213–2·7234, Beud.; fibrous, lamellar, and stalactitic, 2·70–2·72, but when pulverized, 2·729–2·7233. Lustre vitreous—subvitreous—earthy. Color white or colorless; also various pale shades of gray, red, green, blue, violet, yellow; also brown and black when impure. Streak white or grayish. Transparent—opaque. Fracture usually conchoidal, but obtained with difficulty when the specimen is crystallized. Double refraction strong.

The following are some of the irregular forms or conditions in the crystallization of calcite: (1) With *curved* surfaces. The rhombohedron $\frac{1}{4}R$, top part of f. 574, and the hexagonal prism f. 574A, and prism of f. 576. (2) *Spirally group*, f. 573, in which the spires consist of small crystals of the form in f. 552C. (3) *Grouped in curving columns*: one case is mentioned by Kenngott in which the column was a pile of rhombohedrons (form in f. 553B) in a single series, the breadth $\frac{1}{16}$ in. (4) *Made up of a succession of unlike forms*: in f. 576 a prism is surmounted by the form in f. 553B, the crystal, after forming as a hexagonal prism with a rounded summit through indistinct scalenohedral planes, having been completed by a form wholly different; in f. 575 a prism with a rhombohedral termination contains inside a scalenohedron (1^3), showing that it reached nearly its actual height as a scalenohedron, and, moreover, before the new form commenced, the scalenohedron was tipped by a cube of fluorite: f. 579, in which the sunken plane *o* has arisen from additions to the other faces, in the process of completion of the crystal, with none to *o*, the conditions producing that modification having ceased. (5) *Irregular changes in the development of the same form*: in f. 574, the form called *nail-head spar* has the unusual accompaniment of the shank of the nail, made up of very small but similar rhombohedrons; *lateral* development having been prevented for a while (perhaps by an accompanying deposition of sediment) and the form consequently elongating upward by successive additions of small crystals, but finally, when the obstruction is no longer acting, a single crystal taking a broad expansion and topping the column. (6) *Symmetrical arrangement of impurities*: in f. 577, 578, showing the tops of a prism, like f. 552C, the impurities being crystals of pyrite.

573

Phenixville.

The planes in the tables above, with the calculated angles, when not otherwise accredited, are from Zippe, Kryst. rhomb. Kalkhaloides, Denkschr. Ak. Wien, iii. 1854. For the others, Hg stands for Hessenberg, Min. Not., iii., iv., v., vii.; Wr., Wimmer, Jahresb. 1854, 865; Rh., v

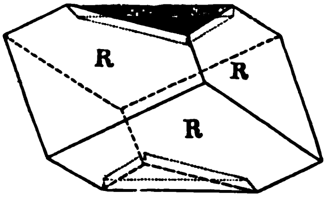
crystal, f. 552B. Sella also enumerates in his table (but not from his own special observations) the forms

$$1^{\frac{11}{3}},\ 1^{4},\ 161^{\frac{3}{4}},\ -\frac{154}{5}^{\frac{3}{5}},\ -\frac{8}{5}^{\frac{7}{3}},\ -\frac{7}{5}^{\frac{9}{7}},\ -\frac{5}{4}^{\frac{13}{5}},\ -\frac{8}{7}^{\frac{9}{4}},\ -\frac{4}{5}^{\frac{4}{3}},\ -\frac{1}{4}^{\frac{11}{3}},\ -\frac{1}{5}^{13}.$$

See also on the crystallography of calcite, F. Hochstetter, Denkschr. Ak. Wien, vi. 89, 1854. Figures 573, 575, 577, 578 are from a paper by J. L. Smith, in Am. J. Sci., xx. 251, the figures drawn by the author; and f. 574 is from Przibram crystals in the cabinet of Prof. Brush. Fig. 561 is from Hessenberg. To the enumerated scalenohedrons add (fr. v. Rath, l. c.) $\frac{1}{3}^{\frac{11}{3}}$, having Y=157° 23′, X=140° 40′, Z=124° 45′.

579



Rossie.

Comp., Var.—Calcite is carbonate of lime, $\dot{C}a\,\ddot{C}$=Carbonic acid 44, lime 56=100. Magnesia, protoxyd of iron, or protoxyd of manganese frequently, and strontia, barytes, oxyd of zinc, or oxyd of lead occasionally, replace part of the lime.

The varieties are very numerous, and diverse in appearance. They depend mainly on the following points: (1) differences in crystallization; (2) in structural condition, the extremes being perfect crystals and earthy massive forms; (3) in color, diaphaneity, odor on friction, due to impurities; (4) in modes of origin.

The following are the most common impurities and their effects:

Red oxyd of iron ($\overset{\cdots}{\mathrm{F}}\mathrm{e}$) produces different shades of red, from flesh-red or paler to opaque blood-red and brownish red, according to the proportions present; the latter Hausmann names *Hæmatoconite* (from αἱμα, *blood*, and κονις, *powder*, Handb., 1304, 1847), as in the marble *Rosso antico* of Italy. The hydrated oxyd ($\overset{\cdots}{\mathrm{F}}\mathrm{e}^2\dot{\mathrm{H}}^3$) causes yellowish to opaque ochre-yellow and yellowish-brown; the deeper, *Sideroconite* of Hausmann (ib., 1306). Protoxyd of iron, oxyd of chrome, silicate of iron, cause shades of green.

Carbonaceous matters, or carbon, give a clear yellowish tint to some crystallized calcite, and various dull colors, from pale drab and buff through gray and bluish-gray to deep black, to compact calcite or limestone; the carbonaceous matters having been derived from the animals of the shells, corals, etc., out of which the limestones were originally made, or from the plants of the same seas, just as soils and mud are now colored from the same cause; and when these carbonaceous matters are allied to petroleum or bitumen, the rock has a fetid or bituminous odor when struck with a hammer. The fact that the dark colors mentioned are due to carbonaceous substances and not to metallic oxyds is proved by the rocks affording, when burnt, *white* quicklime. The black marbles thus colored are named *Anthraconite* (from ἄνθραξ, *coal*) by v. Moll (Ephemer., ii. 305, 1806), *Lucullan* by John (Ch. Unters., 219), and *Lucullite* by Jameson (Min., ii. 180, 1816); they include the *Marmor Luculleum* Plin. (xxxvi. 6). The *Nero Antico* of the Italians belongs here. The bituminous or *fetid* limestones are also called anthraconite when black; and also, from the odor, *Swinestone* (syn. *Stinkstone; Stinkstein*, *Saustein*, *Stinkkalk*, Germ.), some being light gray in color.

Dolomite, or carbonate of lime and magnesia, often constitutes the veins and shells of a compact limestone, as shown by Hunt; and the magnesia found by analysts in such rocks may be generally present as a mixture of dolomite with calcite, rather than as a chemical substitution of magnesia for lime. (See under DOLOMITE.)

Sand, chlorite, and other minerals are sometimes taken up mechanically by crystallizing calcite.

Mica, talc, chlorite, serpentine are often disseminated in crystalline limestones, having been formed in them at the time of their crystallization, and are among the materials which produce the cloudings or variegated colors of such limestones.

The varieties that have been named are as follows:

A. *Well crystallized.*

1. *Ordinary.* Crystals and crystallized masses afford easily cleavage rhombohedrons; and when transparent they are what is called *Iceland Spar*, and also *Doubly-refracting Spar* (Doppel-spath *Germ.*).

The crystals vary in proportions from broad tabular to moderately slender acicular, and take a great diversity of forms. But the extreme kinds so pass into one another through those that are intermediate that no satisfactory classification is possible. Many are stout or short in shape because normally so. But other forms that are long tapering in their full development occur short and stout because abbreviated by an abrupt termination in a broad *o*, or an obtuse rhombohedron (as $-\frac{1}{2}$ or R), or a low scalenohedron (as $\frac{1}{2}^{3}$), or a combination of these forms; and thus the crystals having essentially the same combinations of planes vary greatly in shape. The following groups may answer some purpose in the arrangement of the crystals in a cabinet. They are here characterized by stating the form or forms that are dominant, or most largely developed; and the term *abbreviated* is used as above explained. Intermediate forms may be assigned to the group with which they have the most in common. (*b*) *o* group, or flat tabular (f. 553A); the edges of the tables may be made of prismatic planes, or of rhombohedral, etc. (*c*) Low rhombohedral or nail-head, $-\frac{1}{2}R$, $-\frac{1}{4}R$, etc. (*d*) R group, the fundamental rhombohedron dominant (f. 550). (*e*) $\frac{4}{5}R$, or cuboid group. (*f*) $2R$ group. (*g*) $2R$ abbreviated. (*h*) $4R$ group. (*i*) $4R$ abbreviated. (*j*) Long rhombohedron group, including the longer rhombohedrons, of which 11, 13, −14, are rather common (f. 551). (*k*) Long rhombohedron abbreviated, producing sometimes forms that look much like 3- or 6-sided prisms (f. 553D). (*l*) Low scalenohedron group, as $\frac{1}{4}^{3}$, $\frac{2}{3}^{2}$, etc. (*m*) Ordinary scalenohedron or dog-tooth group, that of 1^{3}, one of the most common of forms (f. 552A, 555–559). (*n*) Same abbreviated (f. 564, 565). (*o*) Long scalenohedron group, or that of 1^{7}, 1^{5}, etc. (*p*) Same abbreviated. (*q*) Prism-scalenohedron group, the scalenohedral planes being combined with an oblong prism *i* (f. 554). (*r*) Prismatic group, the prism *i* being elongated and dominant; and variously terminated.

Prunnerite Esmark, from amygdaloid in Faröe, is calcite in cuboid crystals and massive, smalt-blue to violet in color, brownish-yellow by transmitted light, subtransparent to translucent, and chalcedonic in aspect.

2. *Twin-crystals.* Groups *a*–*f* corresponding to the different kinds described on p. 675.

3. *Crystals with internal impurities, etc.* (*a*) Having interior planes or other evidence of changes in the progress of their formation (f. 575, 576, 579). (*b*) Containing impurities symmetrically arranged.

4. *Spiral or curved aggregations of crystals.* (*a*) Spirally arranged crystals. (*b*) Bent or curved crystallizations.

5. *Pseudomorphous calcite.* *Natrocalcite* includes pseudomorphs of calcite after *celestite* from Sangerhausen, named under the mistaken idea that the material contained soda.

6. *Reichite* (Breith., B. H. Ztg., xxiv. 311) is a pure calcite from Alston-Moor in Cumberland white in color, *with an angle of* 105° 20′, according to Breithaupt's measurements, and G.=2·666–2·677.

B *Varieties, crystallized as well as uncrystallized, based on the presence of other carbonates and of different impurities.*

7. *Dolomitic calcite.* Containing carbonate of magnesia and lime or dolomite—a fact ascertainable only by chemical methods, unless the amount of magnesia be considerable, when it is apparent in crystals in the angle $R \wedge R$.

8. *Ferrocalcite.* Containing carbonate of iron, and turning brown on exposure.

9. *Manganocalcite.* Containing carbonate of manganese, and becoming brownish-black on exposure.

10. *Plumbocalcite* Johnston (Ed. Phil. J., vi. 79, 1829), white to yellowish and reddish-brown, and having $R \wedge R=105^\circ\ 5\frac{3}{4}'$, Breith.; 105° 5′, Dufr.; 105°, Kenng. G.=2·772, v. Hauer; 2·746 −2·748, Descl. Contains some carbonate of lead.

11. *Neotype* Breith. (Handb., 313, 1841). Grayish-white, and occurring in rhombohedrons $2R$; $R \wedge R=105^\circ\ 8'$, Breith. G.=2·819—2·840. Contains some carbonate of barytes. From Cumberland, England.

12. *Spartaite* Breith. (B. H. Ztg., xvii. 53, 1858). White, grayish-white, becoming brownish-black on exposure; $R \wedge R=104^\circ\ 57\frac{1}{2}'$, Breith.; G.=2·808—2·818. Occurs with franklinite and zincite at Sparta, Sterling Hill, Hamburg, N. J., and contains some carbonate of manganese. Shepard proposed the name *calcimangite* for the mineral from Sterling (anal. 6).

13. *Strontianocalcite* Genth (Proc. Ac. Sci. Philad., vi. 114, 1852); in opaque white crystals, occurring in globules which have a surface consisting of the terminations of acute rhombohedrons, and H.=3·5. Contains some strontia, and hence gives a decided red flame before the blowpipe.

14. *Fontainebleau limestone* (Lassonne, Mem. Ac. Paris, 1775, Chaux carbonatée quartzifère *H.*, 1801); crystals of the form in fig. 550c, from Fontainebleau and Nemours, France, which contain a large amount of sand, some 50 to 63 p. c. according to Delesse, with G.=2·53—2·84, the latter from one containing 57 p. c. of sand.

15. *Hislopite* Haughton (Phil. Mag., IV. xvii. 16, 1859) is a grass-green cleavable calcite from Central India, containing about 14 p. c. of a siliceous material like glauconite (q. v.), to which the color is owing.

C. *Varieties based on fibrous or lamellar structure.*

16. *Satin Spar;* fine fibrous, with a silky lustre. Resembles fibrous gypsum, which is also called satin spar, but is much harder and effervesces with acids.

17. *Argentine* Kirwan (Min., i. 104, 1794; *Schieferspath* Hofmann, Bergm. J., 188, 1789; Slate Spar). A pearly lamellar calcite, the lamellæ more or less undulating; color white, grayish, yellowish, or reddish.

18. *Aphrite*, in its harder and more sparry variety (*Schaumspath* Freiesleben), is a foliated white pearly calcite, near argentine; in its softer kinds (*Schaumerde* W., *Silvery Chalk* Kirwan, *Ecume de Terre* H.) it approaches chalk, though lighter, pearly in lustre, silvery-white or yellowish in color, soft and greasy to the touch, and more or less scaly in structure.

D. *Granular massive to cryptocrystalline; Limestone, Marble, Chalk.*

19. *Granular limestone* (*Saccharoidal limestone*, so named because like loaf sugar in fracture). The texture varies from quite coarse to very fine granular, and the latter passes by imperceptible shades into *compact* limestone. The colors are various, as white, yellow, reddish, green, and usually they are clouded and give a handsome effect when the material is polished. When such limestones are fit for polishing, or for architectural or ornamental use, they are called *marbles*. (*a*) *Statuary marble* is pure white, fine grained, and firm in texture. The *Parian* marble from the island of Paros (the *Lychnites* of the ancients), *Pentelican* from the quarries near Athens, *Luni* marbles of the coast of Tuscany, and the *Carrara*, of Modena, Italy, are among the best of statuary marbles. *Architectural* marble includes both white and colored. (*b*) The *Cipolin* of Italy is white, with pale greenish shadings from green talc; it does not stand the weather well. (*c*) *Giallo antico* of Italy is ochre-yellow to cream-yellow, with some whitish spots. (*d*) The *Sienna*, or *Brocatello de Sienna*, is yellow, veined or clouded with bluish-red, having sometimes a tinge of purple. (*e*) The *Mandelato* is a light red with yellowish-white spots. A red kind from Tiree in Scotland has different shades of red, as rose-red, flesh-red, reddish-white; one from Tennessee is clouded with brownish- and purplish-red. (*f*) The *Bardiglio* is gray with crowded dark well-defined cloudings, consisting partly of serpentine, from Corsica. (*g*) *Turquois-blue* marble, from the quarries of Seravezza near Carrara, has a fine grayish-blue color, veined with white. (*h*) *Verd-Antique* is clouded green, the color, owing to the presence of serpentine (see p. 465), yellowish-green to bluish-green.

20. *Hard compact limestone.* Varies from nearly pure white, through grayish, drab, buff, yellowish, and reddish shades, to bluish-gray, dark browish-gray, and black, and sometimes

variously veined. The colors dull, excepting ochre-yellow and ochre-red varieties. Many kinds make beautiful marble when polished.

(*a*) *Black*, (*b*) *yellow*, (*c*) *red*, and (*d*) *fetid* kinds have been mentioned (pp. 676, 677).

The *Portor* (*d*), called sometimes Egyptian marble, is of black color, handsomely veined with yellow dolomite, and comes from Porto-Venere, near Spezia; the rock is of the lower Lias. (*e*) *Panno-di-Morte* (Death's Robe) of Italy is black, with some white fossil shells. (*f*) *Marble of Languedoc* is fine deep red or brownish-red, with some white and gray due to fossils, and is from St. Beaumé in France. (*g*) *Griotte*, from the Dept. of Herault, France, has a reddish-brown base, with somewhat regularly arranged spots of clear red, and some whitish round spots due to goniatites. (*h*) *Sarencolin* marble, from the Pyrenees, is deep red mixed with gray and yellow. (*i*) Bird's-eye marble is gray, with whitish crystalline points, and is from central New York.

(*k*) *Shell-marble* includes kinds consisting largely of fossil shells; (*l*) *Madreporic* marble, those containing corals; (*m*) *Encrinal*, those containing encrinal (crinoidal) remains. (*n*) *Lumachelle* is a dark brown shell-marble, with brilliant fire-like or chatoyant internal reflections proceeding from the shells, and from Bleiberg in Carinthia; and another kind, with the shells yellow, comes from Astrachan.

(*o*) *Ruin-marble* is a kind of compact calcareous marl, showing, when polished, pictures of fortifications, temples, etc., in ruins, due to infiltration of oxyd of iron; from Florence, Italy.

(*p*) *Lithographic stone* is a very even-grained compact limestone, usually of buff or drab color; as that of Solenhofen.

(*q*) *Breccia marble* is made of fragments of limestone cemented together, and is often very beautiful when the fragments are of different colors, or are imbedded in a base that contrasts well. The colors are very various.

(*r*) *Pudding-stone* marble consists of pebbles or rounded stones cemented. It is often called improperly breccia marble.

(*s*) *Hydraulic limestone* is an impure limestone. The French varieties contain 2 or 3 p. c. of magnesia, and 10 to 20 of silica and alumina (or clay). The varieties in the United States contain 20 to 40 p. c. of magnesia, and 12 to 30 p. c. of silica and alumina. A variety worked extensively at Rondout, N. Y., afforded Professor Beck (Min. N. Y., 78) Carbonic acid 34·20, lime 25·50, magnesia 12·35, silica 15·37, alumina 9·13, sesquioxyd of iron 2·25. Oxyd of iron is rather prejudicial to it than otherwise. Vicat observes that in the best French there are 20 to 30 p. c. of clay, and in that only moderately good 10 to 12 p. c. An impure limestone of France, which needs no sand for making the cement, it containing calcite 54 p. c, clay 31, oxyd of iron 15=100, is called *plaster-cement* (Dufr. Min., ii.).

21. *soft compact limestone*. (*a*) *Chalk* is white, grayish-white, or yellowish, and soft enough to leave a trace on a board. The consolidation into a rock of such softness may be owing to the fact that the material is largely the hollow shells of rhizopoda.

The *creta* of the Romans (usually translated *chalk*) was mostly a white clay, true chalk being little known to the ancients. The kind described by Pliny as the most inferior kind of cretaceous earth, and as used for marking the feet of slaves, was probably true chalk.

(*b*) *Calcareous marl* (Mergelkalk *Germ.*) is a soft earthy deposit, often hardly at all consolidated, with or without distinct fragments of shells; it generally contains much clay, and graduates into a calcareous clay.

22. *Concretionary massive*. (*a*) *Oolite* (Rogenstein *Germ.*) is a granular limestone, but its grains are minute rounded concretions, looking somewhat like the roe of fish, the name coming from *ᾠόν*, *egg*. It occurs among all the geological formations, from the Lower Silurian to the most recent, and it is now forming about the coral reefs of Florida. (*b*) *Pisolite* (Erbsenstein *W.*) consists of concretions as large often as a small pea, or even larger, the concretions having usually a distinct concentric structure. It is formed in large masses in the vicinity of the Hot Springs at Carlsbad in Bohemia.

23. *Deposited from calcareous springs, streams, or in caverns, etc.*

(*a*) *Stalactites* are the calcareous cylinders or cones that hang from the roofs of limestone caverns, and which are formed from the waters that drip through the roof; these waters hold some bicarbonate of lime in solution, and leave carbonate of lime to form the stalactite when evaporation takes place. Stalactites vary from transparent to nearly opaque; from a granular crystalline structure to a radiating fibrous; from a white color and colorless to yellowish-gray and brown.

(*b*) *Stalagmite* is the same material covering the floors of caverns, it being made from the waters that drop from the roofs, or from sources over the bottom or sides; cones of it sometimes rise from the floor to meet the stalactites above. It consists of layers; but these are very irregularly curved, or bent, owing to the knobs and conelets that are made over the floor; and polished specimens generally owe much of their beauty to the agate-like or onyx-like bandings.

Stalagmite is the *Alabastrites* (alabaster-stone) in part (if not wholly) of Theophrastus, Pliny, and other ancient writers; that is, the stone of which ointment vases, of a certain form called *alabasters*, were made. (See GYPSUM, p. 640.) A locality near Thebes, now well known, was largely explored by the ancients, and the material has often been hence called Egyptian alabaster. It was also formerly called *onyx* and *onychites;* Horace, in the 3d book of his Odes, speaks of an ointment vase of onyx. Pliny mentions columns of "onyx," or "alabastrites," that were 32 ft. in height, and mentions Damascus as affording a kind whiter than that of Thebes. In the arts it is often now called *Oriental Alabaster;* and sometimes also *Gibraltar-stone*, from the occurrence of the material in a cavern at Gibraltar.

(*c*) *Calc-sinter, Travertine, Calc Tufa.* Travertine (*Confetto di Tivoli*) is of essentially the same origin with stalagmite, but is distinctively a deposit from springs or rivers, especially where in large deposits, as along the river Anio, at Tivoli, near Rome, where the deposit is scores of feet in thickness. It has a very cavernous and irregularly banded structure, owing to its mode of formation. It is the *Lapis Tiburtinus* of Vitruvius, ii. c. 7, and Pliny, xxxvi. 48, etc.; the word *travertine* being a corruption of *tiburtine.* It includes also, especially under the name of *calc tufa*, cellular depositions from the waters of small springs or sources, which often contain fossil leaves, twigs, moss, nuts or seed, etc. The *Osteocollus* (Beinwelle, Beinbruch) Gesner (p. 31, 1565), "qui ossa fracta intra corpus sumptus," as was thought at the time (*osteocolla* of later authors), is, as long since shown, a cellular calc tufa, consisting of incrustings of fragments of reeds or other marsh plants. It means *bone-glue. Inolite*, Gallitzin, is also calc-sinter.

(*d*) *Agaric mineral;* Rock-milk (*Bergmilch, Montmilch*, Germ.) is a very soft, white material, breaking easily in the fingers, deposited sometimes in caverns, or about sources holding lime in solution.

(*e*) *Rock-meal* (*Berg-mehl* Germ., *Farina fossilis* Bruckm., etc.) is white and light, like cotton, becoming a powder on the slightest pressure. It is an efflorescence, and is common near Paris, especially at the quarries of Nanterre.

16. *Carrara Marble*	98·765	—	0·900	—	, $\dddot{S}i$ 0·006, $\overline{\dddot{F}e}$, $\dot{M}n$, $\overline{\dddot{A}l}$ 0·083, sand 0·156, $\overline{\dot{P}}$ and loss 0·090=100 Kæppel.

Natrocalcite afforded Marchand (J. pr. Ch., xlvi. 95) $\dot{C}a\ \ddot{C}$ 94·37, $\overline{\dddot{A}l}$, $\overline{\dddot{F}e}$ 1·15, $\dot{C}a\ \dddot{S}$ 2·02, $\dot{H}$ 1·34, gangue 1·10=99·98. Iodine has been found in certain fossiliferous limestones, as at Gouzon, by Lembert (J. d. Pharm., III. xix. 240).

Pyr., etc.—In the closed tube sometimes decrepitates, and, if containing metallic oxyds, may change its color. B.B. infusible, but becomes caustic, glows, and colors the flame red; after ignition the assay reacts alkaline; moistened with muriatic acid imparts the characteristic lime color to the flame. In borax dissolves with effervescence, and if saturated yields on cooling an opaque, milk-white, crystalline bead. Varieties containing metallic oxyds color the borax and salt of phosphorus beads accordingly. With soda on platinum foil fuses to a clear mass; on charcoal it at first fuses, but later the soda is absorbed by the coal, leaving an infusible and strongly luminous residue of lime. In the solid mass effervesces when moistened with muriatic acid, and fragments dissolve with brisk effervescence even in cold acid.

Obs.—Andreasberg in the Harz is one of the best European localities of crystallized calcite there are other localities in the Tyrol, Styria, Carinthia, Hungary, Saxony, Hesse Darmstadt (at Auerbach), Hesse Cassel, Norway, France, and in England in Derbyshire, Cumberland, Cornwall, Scotland; in Iceland. In Iceland a single rhombohedron (R) over 6 yds. long and 3 high has been observed.

In the U. States, in *N. York*, in St. Lawrence and Jefferson Cos., especially at the Rossie lead mine; crystals highly modified (f. 560, 561), and often transparent even when large; one nearly transparent, in the cabinet of Yale College, weighing 165 pounds; often covered in part by crystals of galenite; at the Natural Dam, 2 m. from Gouverneur, in the same vicinity, good crystals; also at the Wilson vein in Gouverneur, and the Jepson vein in Rossie; at the Parish ore bed in Gouverneur, fine geodes, in specular iron; in Jefferson Co., near Oxbow, on the land of Mr. Benton, from a decomposing limestone, large crystals sometimes as clear as Iceland spar; rose and purple varieties very beautiful; some large crystals of a hundred lbs. and upward; 4. m. S. of Oxbow, in Antwerp, a vein of calcite and lead, which affords beautiful cleavage masses of white, purple, and brownish shades; also interesting crystals; in Essex Co., town of Moriah, on Mill Brook, near Port Henry, crystals of calcite in white limestone; dog-tooth spar (f. 552A, 1^3 and also 1^3, -2), in Niagara Co., near Lockport, with pearl spar, celestite, selenite, and anhydrite; in Onondaga Co., near Camillus, along the railroad; good crystals in Herkimer Co., 1 m. S. of Little Falls, in the bed of a small stream; in Lewis Co., at Leydon and Lowville, and at the Martinsburg lead mine; on the western bank of Dry Sugar River, near Boonville, Oneida Co. (f. 552C); at Anthony's Nose on the Hudson, formerly groups of large tabular crystals (f. 553A); at Watertown, *Agaric mineral*, covering the sides of a cave; at Schoharie, fine *stalactites* in many caverns, of which Ball's cave is the most famous; at Camillus and Schoharie (near the barite locality), *fibrous*, in considerable abundance, and at De Long's Mill, St Lawrence Co., of a fine satin lustre. In *Maine*, at Thomaston, lenticular and prismatic crystals, common. In *N. Hamp.*, at the iron mines, Franconia, *argentine*. In *Mass.*, at Williamsburg and Southampton, *argentine*. In *Conn.*, at the lead mine, Middletown, in crystals (i-2, $-\frac{1}{2}$, I, short or long, and 1^3, R). In *N. Jersey*, at Bergen, fine crystallizations of yellow calcite, with datolite, etc., in trap (f 552B); at Franklin, a pink variety, and good cleavage specimens. In *Penn.*, in York Co., Iceland spar. In *Virginia*, at the celebrated Wier's cave, *stalactites* of great beauty; also in the large caves of *Kentucky*. At the Lake Superior copper mines, splendid crystals often containing scales of native copper.

At Warsaw, Illinois, in great variety of form, lining geodes and implanted on quartz crystals; at Quincy, Ill.

In Nova Scotia, at Partridge I., a wine-colored calcite, and other interesting varieties.

Corals, of which large reefs are formed in tropical regions, consist mainly of carbonate of lime. B. Silliman, Jr., obtained for a recent species of Madrepora (Dana's Report on Zoophytes, and also Am. J. Sci., II. i. 189) Carbonate of lime 94·807, phosphates, fluorids, etc., 0·745, organic matter 4·448. And the deposit of phosphates and fluorids afforded the percentage—$\ddot{\mathrm{Si}}$ 12·5, $\dot{\mathrm{Ca}}$ 7·5, $\dot{\mathrm{Mg}}$ 4·2, Mg F 26·62, Ca F 26·34, $\dot{\mathrm{Mg}}\,\ddot{\mathrm{P}}$ 8·00, $\dddot{\mathrm{Al}}$ and $\dddot{\mathrm{Fe}}$ 14·84. Other analyses gave similar results.

The material of the common marbles is either granular or compact limestone. These rocks when burnt form quicklime.*

Alt.—Calcite occurs under the forms of dolomite, calamine, spathic iron, malachite, azurite, gypsum, smithsonite, barite, fluorite, limonite, göthite, red iron ore, minium, meerschaum, chlorite, quartz, chalcedony, garnet, feldspar, mica, pyrolusite, hausmannite, manganite, marcasite, galenite, blende, native copper. The change to *dolomite*, as Bischof explains, may take place through bicarbonate of magnesia in solution; to *spathic iron* ($\dot{\mathrm{Fe}}\,\ddot{\mathrm{C}}$) through sulphate of iron in solution, forming sulphate of lime and carbonate of iron; or by carbonated waters containing bicarbonate of iron, which slowly dissolve calcite, while the carbonate of iron takes its place, forming a pseudomorph by substitution; to *smithsonite* ($\dot{\mathrm{Zn}}\ddot{\mathrm{C}}$) through sulphate of zinc in solution; to *calamine* ($\dot{\mathrm{Zn}}^3\,\ddot{\mathrm{Si}}+1\frac{1}{2}\,\dot{\mathrm{H}}$) probably by a change first to $\dot{\mathrm{Zn}}\,\ddot{\mathrm{C}}$ and then to the silicate, through alkaline silicates in solution; to *malachite* through a solution of sulphate of copper, which forms carbonate of copper and sulphate of lime; to *gypsum* or *anhydrite* through the action of sulphuric acid, which acid is produced by the oxydation of sulphuretted hydrogen or otherwise, thus forming sulphate of lime; to *quartz* by waters containing alkaline silicates, which afford free silica; to *fluorite*, *limonite*, and other species, by the removal of the $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$ by waters which hold carbonic acid or alkaline silicates, and at the same time contain the ingredients forming the replacing mineral. *Limonite* or *red iron ore* might result from the decomposition of pyrite in the vicinity.

Hollow scalenohedrons from the province of Arnsberg were found by Nöggerath (Verh. nat. Ver. Bonn, 1863, 137) to consist of an exterior coating of azurite, and an interior layer of malachite.

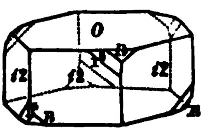
580



Rhombohedral. $R \wedge R = 106°\ 15'$, $O \wedge R = 136°\ 8\tfrac{1}{2}'$, $a = 0{\cdot}8322$. Observed planes: O, i-2, R, 4, -2, $-\tfrac{1}{2}$, 1^s, 1^s (hemihedral). $O \wedge i\text{-}2 = 90°$, $O \wedge 4 = 104°\ 35'$, $O \wedge 2 = 117°\ 29'$, $O \wedge \tfrac{1}{2} = 154°\ 20'$, $\tfrac{1}{2} \wedge \tfrac{1}{2} = 135°\ 57'$, $2 \wedge 2 = 79°\ 36'$. $R \wedge R$ varies between 106° 10′ and 106° 20′. An increase of 100° C. diminishes the angle 4′. Cleavage: R perfect. Faces R often curved, and secondary planes usually with horizontal striæ. Twins: similar to f. 572, page 673. Also in imitative shapes; also amorphous, granular, coarse or fine, and grains often slightly coherent.

H.=3·5—4. G.=2·8—2·9, true dolomite. Lustre vitreous, inclining to pearly in some varieties. Color white, reddish, or greenish-white; also rose-red, green, brown, gray, and black. Subtransparent to translucent. Brittle.

Comp., Var.—Normal or true dolomite has the formula $\dot{Ca}\,\ddot{C} + \dot{Mg}\,\ddot{C}$=Carbonate of lime 54·35, carbonate of magnesia 45·65. Some kinds included under the name have the two carbonates in other proportions; but this may arise from their being mixtures of dolomite with calcite or magnesite. Protoxyd of iron replaces part of the magnesia in some dolomite; so also protoxyd of manganese; and more rarely oxyd of cobalt or zinc.

The varieties are the following:

(1) *Crystallized.* *Pearl spar* includes rhombohedral crystallizations with curved faces.

(2) *Columnar* or fibrous.

Miemite, from Miemo, Tuscany, is either in crystals, columnar, or granular, and pale asparagus-green in color.

(3) *Granular*, or *saccharoid*, constitutes many of the kinds of white statuary marble, and white and colored architectural marbles, names of some of which have been mentioned under calcite.

(4) *Compact massive*, like ordinary limestone. Many of the limestone strata of the globe are here included, and much *hydraulic limestone*, noticed under calcite.

(5) *Compact porcellanous*, *Gurhofian*; snow-white and subtranslucent, with a conchoidal fracture, sometimes a little opal-like; from Gurhof, in lower Austria.

(6) *Ferriferous; Brown spar*, in part. Contains carbonate of iron, and as the proportion increases it graduates into ankerite (q. v.). The color is white to brown, and becomes brownish on exposure through the oxydation of the iron. A columnar kind, containing 10 p. c. of carbonate of iron, has been called *Brossite* (anal. 19); G.=2·915. *Tharandite*, from Tharand, near Dresden, is crystallized, and contains 4 p. c. of $\dot{Fe}$.

(7) *Manganiferous.* Colorless to flesh-red. $R \wedge R = 106°\ 28'$ (anal. 20, by Ettling); 106° 16′ (anal. 21, by Ott).

(8) *Cobaltiferous.* Colored reddish (anal. 23); G.=2·921, Gibbs.

(9) The varieties based on variations in the proportions of the carbonates are the following: (*a*) *Normal dolomite*, ratio of $\dot{Ca}\,\ddot{C}$ to $\dot{Mg}\,\ddot{C}$=1 : 1 (anal. 1–24); (*b*) ratio $1\tfrac{1}{2}$: 1=3 : 2 (anal. 25–30); (*c*) ratio=2 : 1 (anal. 31–33), includes *gurhofian* or *gurhofite*; (*d*) ratio 3 : 1 (anal. 34); (*e*) ratio=5 : 1 (anal. 35); (*f*) ratio 1 : 3 (anal. 36, 37), or *conite*. The last (*f*) may be dolomitic magnesite; and the others, from *b* to *e*, dolomitic calcite, or calcite + dolomite. The manner in which dolomite is often mixed with calcite, forming its veins and its fossil shells (see below), shows that this is not improbable.

Analyses: Ratio 1 : 1. 1, Suckow (J. pr. Ch., viii. 408); 2, Lavizzari (Jahrb. Min. 1845, 302, 1846, 580); 3, Abich (G. Beob., p. iv.); 4, J. Roth (J. pr. Very many of the limestone strata of the globe are thus partly or wholly dolomitic, though usually not as pure as in the above analyses. T. S Hunt says that dolomites make up the chief part of the Calciferous, Clinton, Trenton, Guelph, Niagara, and Onondaga limestones of Canada (Logan's Rep., 1863, 456). In 1857 (Logan's Rep., 1857, 200) he announced that the veins and shells of some ordinary limestones were magnesian. In the Portor marble (p. 679) the body of the rock contains only 1·0 p. c. of carbonate of magnesia, and the veins 35·5 p. c. A limestone from Dudswell, Canada, contains Ċa C̈ 92·5, Ṁg C̈ 1·3, sand 6·2; and the fossils are of similar composition; but a yellowish material enveloping the fossils and filling veins consists of Ċa C̈ 56·60, Ṁg C̈ 11·76, Ḟe C̈ 3·23, with 26·72 insoluble=98·31. This being a mixture of dolomite and calcite, the latter was removed by acetic acid, and the residue, 52 p. c., then afforded Ċa C̈ 51·75, Ṁg C̈ 35·73, Ḟe C̈ 12·52=100. In the Trenton limestone of Ottawa, the fossil corals, shells, and crustaceans are changed to whitish dolomite; and a fragment of an Orthoceras gave Ċa C̈ 56·00, Ṁg C̈ 37 80, Ḟe C̈ 5·95=99·75.

Pyr., etc.—B.B. acts like calcite, but does not give a clear mass when fused with soda on platinum foil. Fragments thrown into cold acid are very slowly acted upon, while in powder in warm acid the mineral is readily dissolved with effervescence. The ferriferous dolomites become brown on exposure.

Obs.—Massive dolomite constitutes extensive strata, called limestone strata, in various regions. Crystalline and compact varieties are often associated with serpentine and other magnesian rocks, and with ordinary limestones. Some of the prominent localities are at Salzburg, the Tyrol, Schemnitz in Hungary, Kapnik in Transylvania, Freiberg in Saxony, the lead mines at Alston in Cumberland, etc.

In the U. States, in *Vermont*, at Roxbury, large, yellow, transparent crystals of the rhomb-spar variety, in talc. In *Rhode Island*, at Smithfield, a coarse cleavable variety, occasionally presenting perfect crystals, with white talc in calcite. In *N. Jersey*, at Hoboken, white hexagonal crystals (f. 580), and in rhombohedrons. In *N. York*, at Lockport, Niagara Falls, and Rochester, with calcite, celestite, and gypsum; also at Glenn's Falls; in Richmond Co., at the quarantine, crystallized dolomite, in rhombohedrons, and at the Parish ore bed, St. Lawrence Co.; on Hustis's farm in Phillipstown, a variety resembling *Gurhofite*, with a semi-opaline appearance and a fracture nearly like porcelain.

Dolomite is generally supposed to be injurious as a manure for soils, on account of its magnesia; but this is not so, unless used after calcination, before it is fully air-slaked. The lime it affords when burnt makes a more durable cement than common limestone.

Named after Dolomieu, who announced some of the marked characteristics of the rock in 1791—its not effervescing with acids, while burning like limestone, and soluble after heating in acids. He observes in his paper that, as early as 1786, he had found the white marble of many of the ancient statues and monuments of Italy to consist of this peculiar rock; and eighteen months before the date of his paper he discovered "immense quantities of similar limestones" in the Tyrol.

Woulfe, in the Phil. Trans. for 1779 (at p. 29), describes a ferriferous dolomite or ankerite, with some analytical determinations, which was in pearly rhombohedrons, resembling somewhat those of spathic iron, and came from Joachimsthal. "In its natural state" it effervesced strongly with "rectified" muriatic acid, which would indicate the presence of more iron than he obtained (5 or 6 p. c. of Fe O, C O_2). It may have been ankerite.

Alt.—Dolomite occurs altered to spathic iron, calamine, steatite, limonite, red iron ore, göthite pyrolusite, and quartz, and by processes similar to those explained under calcite.

717. ANKERITE. Dolomite pt. Brown Spar and Pearl Spar pt. Paratomes Kalk-Haloid *Mohs*, Grundr., i. 536, 1822, ii. 116, 1824. Rohwand, Wandstein, *Styrian Miners*. Ankerit *Haid.*, Mohs's Min., i. 100, 1825. Tautoklin *Breith.*, Char., 70, 1832, Uib., 20, 1830.

Rhombohedral. $R \wedge R = 106° 12'$, Styria, Mohs; 106° 6′, Belnhausen (anal. 6), Ettling. Also crystalline massive, coarse or fine granular, and compact.

H.=3·5—4. G.=2·95—3·1. Lustre vitreous to pearly. Color white, gray, reddish. Translucent to subtranslucent.

Comp.—$\dot{Ca}\ddot{C}+(\dot{Mg}, \dot{Fe}, \dot{Mn})\ddot{C}$, or a dolomite in which the magnesia is more or less completely replaced by protoxyd of iron, or of iron and manganese. By the increase in the proportion of the magnesian carbonate to the iron and manganesian, the mineral graduates into true dolomite. The kinds with 10 p. c. or less of carbonate of iron are placed under dolomite, and those with more, having G. above 2·95, under ankerite.

The ratios of $\dot{Mg}\ddot{C}$ to $(\dot{Fe}, \dot{Mn})\ddot{C}$ in the analyses below are as follows:

1.	1 : 2	6.	1·7 : 1	11.	2·7 : 1
2.	1 : 2½	7.	1·5 : 1	12.	3 : 1
3.	1 : 1·1	8.	2 : 1	13.	2·8 : 1
4.	1·3 : 1	9.	2 : 1	14.	3·1 : 1
5.	1 : 1	10.	2·1 : 1	15.	4 : 1

Tautoclin Breith., is a grayish-white variety, containing about 15 p. c. of carbonate of iron, and having G.=2·961, Ettling; from Beschertglück, near Freiberg in Saxony (anal. 11).

Analyses: 1, Fridau (Haid. Ber., v. 1); 2, Schrotter (Baumg. ZS., viii. 1); 3, Luboldt (Pogg., cii. 455); 4, v. Hauer (Jahrb. G. Reichs., iv. 827); 5, Schmidt (Ramm. Min. Ch., 217); 6, Ettling (Ann. Rhombohedral. $R \wedge R$=107° 29′, $O \wedge R$=136° 56′; a=0·8095 Cleavage: rhombohedral, perfect. Also massive; granular to very compact.

H.=3·5—4·5. G.=3—3·08, cryst.; 2·8, earthy; 3—3·2, when ferriferous. Lustre vitreous; fibrous varieties sometimes silky. Color white, yellowish or grayish-white, brown. Transparent—opaque. Fracture flat conchoidal.

Var.—1. *Ordinary.* (*a*) Crystallized. In distinct rhombohedral crystals; $R \wedge R$=107° 28′, fr. Snarum, Breith.; 107° 16′, fr. Tragössthal (anal. 4), Fœtterle. (*b*) *Lamellar*; cleavable. (*c*) *Compact*, fine, granular; (*d*) Compact, and like unglazed porcelain in fracture. (*e*) *Earthy*; being mixed with hydrated silicate of magnesia or sepiolite (meerschaum); including the *Baudisserite*, from Baudissero, near Turin, which has some resemblance to chalk, and adheres to the tongue Even the purer varieties of compact magnesite usually contain more or less of the silicate.

2. *Ferriferous*, *Breunerite*; containing several p. c. of protoxyd of iron; G.=3—3·2; white, yellowish, brownish, rarely black and bituminous; often becoming brown on exposure, and hence called *Brown Spar*. $R \wedge R$ in mineral fr. Salzburg (anal. 16) 107° 32′, Dufr.; fr. Pfitsch (anal. 21) 107° 22½′, Mitscherlich; fr. Tyrol (anal. 19) 107° 25′, Brooke, 107° 25½′ Breith. The name *Breunerite* was originally given by Haidinger (after M. Breuner) to the variety analyzed by Stromeyer containing 5 to 10 p. c. of protoxyd of iron (or 8 to 17 p. c. of carbonate); and *Walmstedtite* to an included kind from the Harz, analyzed by Walmstedt (anal. 18), differing only in containing a little more protoxyd of manganese than usual (2 p. c.).

Comp.—Carbonate of magnesia, $\dot{M}g\,\ddot{C}$=Carbonic acid 52·4; magnesia 47·6=100; but protoxyd of iron often replacing some magnesia. The ferriferous part may be present as *mesitine* mixed with true magnesite.

Ratio of $\dot{M}g\ddot{C}$ to $\dot{F}e\ddot{C}$ in the preceding analyses:

14.	25 : 1	18.	9 : 1	21.	7 : 1
15.	12 : 1	19.	9 : 1	22.	6 : 1
16.	12 : 1	20.	8 : 1	23.	4 : 1
17.	11 : 1				

T. S. Hunt (Logan's Rep., 1863, 457, 611) found the magnesite rock of Canada to contain 8 to 10½ p. c. of carbonate of iron, with 8 to 40 p. c. of insoluble matters, mostly mixed quartz. That of Sutton afforded $\dot{M}g\ddot{C}$ 83·35, $\dot{F}e\ddot{C}$ 9·02, mixed silica 8·03=100·40.

The white portions of the verd-antique of Roxbury, Mass., are magnesite with about 4 p. c. of carbonate of iron, as shown by Jackson, Hayes, and Hunt.

In the baudisserite, Berthier found $\ddot{C}$ 41·80, $\dot{M}g$ 39·00, meerschaum 19·20=100 (Ann. d. M., 1822, 316). A variety of the same was early analyzed by Giobert (J. d. M., xx. 291, 401, 1808), and another, from Castellamonte, by Guyton (Ann. d. Ch., xlvii. 85, 1803).

A magnesite from Sasbach, Kaiserstuhl, contains hydromagnesite. P. Meyer found (Ann. Ch. Pharm., cxv. 129), after separating the impurities, $\ddot{C}$ 45·27, $\dot{M}g$ 47·69, $\dot{C}a$ 2·47, $\dot{H}$ 4·57, equivalent to $\dot{M}g\ddot{C}$ 82·88, $\dot{C}a\ddot{C}$ 4·41, $\dot{M}g$ 8·14, $\dot{H}$ 4·57.

Pyr., etc.—B.B. resembles calcite and dolomite, and like the latter is but slightly acted upon by cold acids; in powder is readily dissolved with effervescence in warm muriatic acid.

Obs.—Found in talcose schist, serpentine, and other magnesian rocks; as veins in serpentine, or mixed with it so as to form a variety of verd-antique marble (*magnesitic ophiolite* of Hunt); also, in Canada, as a rock, more or less pure, associated with steatite, serpentine, and dolomite. The breunerite variety has been found in a meteorite from Orgueil (Descl.).

Occurs at Hrubschütz in Moravia, where it was first discovered by Mitchell; at Kraubat and Tragössthal, Styria; at Frankenstein in Silesia; Snarum, Norway; Baudissero and Castellamonte in Piedmont; at other localities above mentioned. In America, at Bolton, Mass., in indistinctly fibrous masses, traversing white limestone; at Lynnfield, Cavendish, and Roxbury, Mass., mixed with or veining serpentine; at Barehills, near Baltimore, Md.; in Penn., in crystals at West Goshen, Chester Co.; near Texas, Lancaster Co.; as a rock, in Sutton and Bolton, Canada East; in Canton Upata, Venezuela, near Mission Pastora, looking like porcelain in the fracture, as observed by N. S. Manross: in Tulare, Alameda, Mariposa, and Tuolumne Cos., California.

Delametherie, in his Théorie de la Terre, ii. 93, 1795, uses the name magnesite for the carbonate of magnesia, sulphate, nitrate, and muriate, and the carbonate is placed first in the series. Brongniart, in his Mineralogy, ii. 489, 1807, applies the name to a group, including (1) the carbonate called *Mitchell's magnesite*, (2) meerschaum, (3) the Piedmont magnesite, and (4) other siliceous varieties. As both Brongniart and Delametherie gave the *first* place to the carbonate, the name magnesite would rightly fall to it in case of the division of the group. Karsten, in his Tabellen, 1808, recognized this division of the species, and formally gave to the carbonate the name *magnesite*. The German mineralogists have followed Karsten, as should have been done by all. But in France, Beudant, in 1824, gave the name *giobertite* to the *carbonate*, leaving *magnesite* for the silicate, and most of the French mineralogists have followed Beudant. Giobert analyzed only the siliceous variety from Baudissero, the true composition of the mineral having been ascertained by Lampadius, somewhat earlier, from specimens brought by Mitchell from Moravia.

719. MESITITE. Mesitinspath pt. *Breith.*, Pogg., xl. 170, 1827. Mesitin *Breith.*, Pogg., lxx. 148, 1847.

Rhombohedral. $R \wedge R$=107° 14′. Cleavage rhombohedral, perfect. H.=4–4·5. G.=3·33–3·36. Lustre vitreous, or a little pearly. Color yellowish-white, yellowish-gray, yellowish-brown. Streak nearly white, or colorless. Transparent to subtranslucent.

Comp.—$2\dot{M}g\ddot{C}+\dot{F}e\ddot{C}$=Carbonate of magnesia 59·2. carbonate of iron 40·8=100. Analyses 1, Gibbs (Pogg., lxxi. 566); 2, Fritzsche (Pogg., lxx. 146); 3, Patera (Haid. Ber., ii. 296):

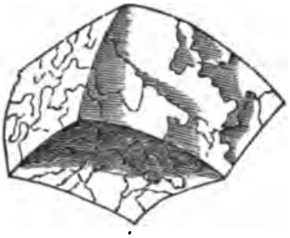
Rhombohedral. $R \wedge R$=107°, $O \wedge R$=136° 37′; a=0·81715. Observed planes: rhombohedral, 1, 4, –5, –2, $-\frac{1}{2}$; scalenohedral, 1^3; pyramidal, $\frac{4}{3}$-2; prismatic, I, i-2; and basal, O. The faces often curved, as below.

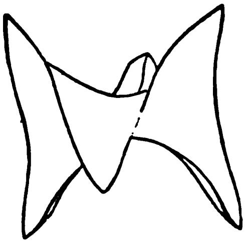
$O \wedge 2 = 117° \; 53'$ $\quad \frac{1}{2} \wedge \frac{1}{2} = 136° \; 34'$ $\quad 4 \wedge 4 = 66° \; 18'$
$O \wedge \frac{4}{3}\text{-}2 = 132 \; 30$ $\quad i \wedge R = 133 \; 23$ $\quad i\text{-}2 \wedge 1^3 = 155 \; 45$

Cleavage: rhombohedral, perfect. Twins: plane of composition $-\frac{1}{2}$. Also in botryoidal and globular forms, subfibrous within, occasionally silky fibrous. Often cleavable massive, with cleavage planes undulating. Coarse or fine granular.

581



582



H.=3·5—4·5. G.=3·7—3·9. Lustre vitreous, more or less pearly. Streak white. Color ash-gray, yellowish-gray, greenish-gray, also brown and brownish-red, rarely green; and sometimes white. Translucent-subtranslucent. Fracture uneven. Brittle.

Comp., Var.—Carbonate of iron, $\dot{\rm Fe}\,\ddot{\rm C}$=Carbonic acid 37·9, protoxyd of iron 62·1. But part of the protoxyd of iron ($\dot{\rm Fe}$) usually replaced by manganese, and often by magnesia or lime.

The principal varieties are the following:

(1) *Ordinary.* (*a*) *Crystallized.* (*b*) *Concretionary*=*Spherosiderite*; in globular concretions, either solid or concentric scaly, with usually a fibrous structure. (*c*) *Granular* to *compact massive.* (*d*) *Oolitic*, like oolitic limestone in structure. (*e*) *Earthy*, or stony, impure from mixture with clay or sand, constituting a large part of the clay iron-stone of the Coal formation and other stratified deposits; H.=3 to 7, the last from the silica present; G.=3·0—3·8, or mostly 3·15—3·65.

(2) Through differences in the bases replacing part of the iron, there are the following kinds:

A. Containing little or no manganese ($\dot{\rm Mn}$), magnesia ($\dot{\rm Mg}$), or lime ($\dot{\rm Ca}$). G.=

B. Containing 5 to 12 p. c. of $\dot{\rm Mn}$, with little $\dot{\rm Mg}$ or $\dot{\rm Ca}$=7 $\dot{\rm Fe}\,\ddot{\rm C}+\dot{\rm Mn}\,\ddot{\rm C}$ to 4 $\dot{\rm Fe}\,\ddot{\rm C}+\dot{\rm Mn}\,\ddot{\rm C}$.

C. Containing 17 to 18 p. c. of $\dot{\rm Mn}$=2½ $\dot{\rm Fe}\,\ddot{\rm C}+\dot{\rm Mn}\,\ddot{\rm C}$.

D. Containing 25 p. c. of $\dot{\rm Mn}$=1½ $\dot{\rm Fe}\,\ddot{\rm C}+\dot{\rm Mn}\,\ddot{\rm C}$; the *oligonspar* of Breithaupt, or *oligonite*, having $R \wedge R = 107° \; 4'$; G.=3·714—3·745; color yellowish to between flesh- and iron-red; streak yellowish-white; remarkably phosphorescent when heated.

E. Containing little manganese and much magnesia, 4 $\dot{\rm Fe}\,\ddot{\rm C}+\dot{\rm Mg}\,\ddot{\rm C}$.

F. Ditto, 2 $\dot{\rm Fe}\,\ddot{\rm C}+\dot{\rm Mg}\,\ddot{\rm C}$, the *sideroplesite*, Breith., from Pöhl, having $R \wedge R = 107° \; 6'$, Breith.: G.=3·616—3·660. Also from other localities. Von Zepharovich obtained from a cleavage rhombohedron from Salzburg (anal. 21) $R \wedge R = 107° \; 5' \; 16''$, and G.=3·699.

G. Containing 20 p. c. of carbonate of lime, and looking like some calamine, the color green; from Altenberg; formula 8 $\dot{\rm Fe}\,\ddot{\rm C}+2\,\dot{\rm Mn}\,\ddot{\rm C}+3\,\dot{\rm Ca}\,\ddot{\rm C}$.

H, I. Other miscellaneous kinds.

The *siderodot* of Breithaupt is a calciferous spathic iron from Radstadt in Salzburg, having G.=3·41.

Analyses: *Division* A. 1, 2, Karsten (Karst. Archiv., ix. 220); 3, Thomson (Min., i. 445); 4, Stromeyer (Unters.); 5, Bischof (Rammelsb. Min. Chemie, 222); 6, Berthier (Ann. d. Schnabel has analyzed many ores from different mines in Siegen, referable to division B (see l. c.).

Pyr., etc.—In the closed tube decrepitates, evolves carbonic oxyd and carbonic acid, blackens and becomes magnetic. B.B. blackens and fuses at 4·5. With the fluxes reacts for iron, and with soda and nitre on platinum foil generally gives a manganese reaction. Only slowly acted upon by cold acid, but dissolves with brisk effervescence in hot muriatic acid. Exposure to the atmosphere darkens its color, rendering it often of a blackish-brown or brownish-red color.

Obs.—Siderite occurs in many of the rock strata, in gneiss, mica slate, clay slate, and as clay iron stone in connection with the Coal formation and many other stratified deposits. It is often associated with metallic ores. At Freiberg it occurs in silver mines. In Cornwall it accompanies tin. It is also found accompanying copper and iron pyrites, galenite, vitreous copper, etc. In New York, according to Beck, it is almost always associated with specular iron. Occasionally it is to be met with in trap rocks as *spherosiderite*.

In the region in and about Styria and Carinthia this ore forms extensive tracts in gneiss, which extend along the chain of the Alps, on one side into Austria, and on the other into Salzburg. At Harzgerode in the Harz, it occurs in fine crystals in gray-wacke; also in Cornwall, Alston-Moor and Devonshire.

The *Spherosiderite* occurs in greenstone at Hanau, Steinheim, and Dransberg, and many other places. Clay iron-stone, which is a siliceous or argillaceous carbonate of iron, occurs in coal beds near Glasgow; also at Mouillar, Magescote, etc., in France, etc.

In the United States, in *Vermont*, at Plymouth. In *Mass.*, at Sterling. In *Conn.*, at Roxbury, an extensive vein in quartz, traversing gneiss; at Monroe, Lane's mine, in small quantities. In *N. York*, at the Sterling ore bed in Antwerp, Jefferson Co., in rhombohedral crystals; at the Rossie iron mines, St. Lawrence Co. In *N. Carolina*, at Fentress and Harlem mines. The argillaceous carbonate, in nodules and beds (clay iron-stone), is abundant in the coal regions of Penn., Ohio, and many parts of the country. In a clay-bed under the Tertiary along the west side of Chesapeake Bay for 50 m.

Named *Spherosiderite* by Hausmann in 1813, from the concretionary variety, and retained by him for the whole. Haidinger reduced the name to *Siderite*, the prefix *sphero* being applicable only to an unimportant variety. Beudant's name *Siderose* has an unallowable termination. *Chalybite*, Glöcker, should yield to Haidinger's earlier name siderite, as recognized by v. Kobell and Kenngott.

Alt.—Spathic iron becomes brown or brownish-black on exposure, owing to a peroxydation of the iron and its passing to *limonite* ($\overline{\mathrm{Fe}}^2\dot{\mathrm{H}}^3$); and by a subsequent loss of water, it may pass to *red iron ore* or *specular iron* ($\overline{\mathrm{Fe}}$), or to *magnetite* ($\dot{\mathrm{Fe}}\,\overline{\mathrm{Fe}}$), the last at times a result of deoxydation of $\overline{\mathrm{Fe}}$ by organic substances. It also changes by substitution, or through the action of alkaline silicates, to *quartz*.

722. RHODOCHROSITE. Magnesium acido aëreo mineralisatum *Bergm.*, Sciagr., 1782 (without descr. or loc.). Rother Braunsteiners [=Red Manganese Ore], Rothspath, Magnesium ochraceum rubrum, Oxide de manganèse couleur de rose, pt., *of later part of 18th cent.* (it being confounded with the silicate analyzed by Ruprecht in 1782, and Bergmann's announcement being doubted). Luftsaures Braunsteiners (or Carbonate, after Bergm.) pt. *Lenz*, Min., ii. 1794 (with mention of druses of small crystals in "Rhomben," others in "Pyramiden," but with cit. of Ruprecht's anal.). Manganèse oxydé carbonaté (after Bergm.) *H.*, Tabl. comp., 111, 1809. Dichter Rothstein pt. *Hausm.*, Handb., 302, 1813. Rhodochrosit, ? Kohlensaures Magnesium oxydul (fr. Lampadius's anal. of a Kapnik sp'n, in his Pr. Ch. Abh., iii. 239, 1800), *Hausm.*, ib., 1081, 1813. Carbonate of Manganese. Manganspath *Wern.* Dialogite *Jasche*, Germar, Schw. J., xxvi. 119=Blättrige Rothmanganerz *Jasche*, Kl. Min. Schrift., 4, 1817. Diallogite (wrong Orthogr.). Rosenspath, Himbeerspath, *Breith.*, Handb., 228, 229, 1841 (Char., 67, 68, 1832).

Rhombohedral. $R \wedge R = 106°\ 51'$, $O \wedge R = 136°\ 31\frac{1}{2}'$; $a = 0{\cdot}8211$. Observed planes: O; rhombohedrons, R, $-\frac{1}{2}$, -2; scalenohedrons, 1^3, $\frac{1}{4}^3$; prism, i-2. Cleavage: R, perfect. Also globular and botryoidal, having a columnar structure, sometimes indistinct. Also granular massive; occasionally impalpable; incrusting.

H.=3·5—4·5. G.=3·4—3·7; 3·592, Kapnik. Lustre vitreous inclining to pearly. Color shades of rose-red; yellowish-gray, fawn-colored, dark red, brown. Streak white. Translucent—subtranslucent. Fracture uneven. Brittle.

Comp.—$\dot{\mathrm{Mn}}\,\ddot{\mathrm{C}}$=Carbonic acid 38·6, protoxyd of manganese 61·4; but part of the $\dot{\mathrm{Mn}}$ usually replaced by lime ($\dot{\mathrm{Ca}}$), and often, also, by magnesia ($\dot{\mathrm{Mg}}$), or iron ($\dot{\mathrm{Fe}}$); and sometimes by cobalt ($\dot{\mathrm{Co}}$), when the color is of a deeper red, and G.=3·6608, Bergemann (anal. 11). Analyses: 1, Grüner (Ann. d. M., III. xviii. 61); 2, Berthier (Ann. d. M., vi. 595); 3–5, Stromeyer (G. Anz. Gött., 1081, 1848); 6, Kersten (J. pr. Ch., xxxvii. 163); 7, 8, R. Kane (Phil. Mag., Jan., 1848) 9, Hildebrand (Verh. nat. Nassau, xiv. 434); 10, Birnbacher (Ann. Ch. Pharm., xcviii. 144); 11, Bergemann (Verh. nat. Ver. Bonn, 111, 1857):

Pyr., etc.—B.B. changes to gray, brown, and black, and decrepitates strongly, but is infusible With salt of phosphorus and borax in O.F. gives an amethystine-colored bead, in R.F. becomes colorless. With soda on platinum foil a bluish-green manganate. Dissolves with effervescence in warm muriatic acid. On exposure to the air changes to brown, and some bright rose-red varieties become paler.

Obs.—Occurs commonly in veins along with ores of silver, lead, and copper, and with other ores of manganese.

Found at Schemnitz and Kapnik in Hungary; Nagyag in Transylvania; near Elbingerode in the Harz; at Freiberg in Saxony; at Glendree in the County of Clare, Ireland, where it forms a layer 2 in. thick below a bog, and has a yellowish-gray color (anal. 7, 8); botryoidal at Harts hill in Warwickshire.

It has been observed in a pulverulent form, coating triplite, at Washington, Conn., on the land of Joel Camp; in New Jersey, with franklinite at Mine Hill, Franklin Furnace. Abundant at the silver mines of Austin, Nevada; at Placentia Bay, Newfoundland, in slates, fawn-colored and brown, containing 84·6 $\dot{M}n\ddot{C}$, with 14·4 silica.

Named *rhodochrosite* from ῥόδον, *a rose*, and χρῶσις, *color;* and *dialogite*, from διαλογή, *doubt*. The latter name is attributed to Jasche by Germar (l. c.).

Alt.—Quartz pseudomorphs occur near Klein-Voigtsberg.

723. SMITHSONITE. Calamine pt. Galmei pt. Zincum acido aëro mineralisatum *Bergm.*, Sciagr., 144, 1782, Opusc., ii. 209, 1780 (from his own anal.). Zinkspath, Kohlengalmei, *Germ.* Carbonate of Zinc. Smithsonite *Beud.*, Tr., ii. 354, 1832. Zinkspath, Kapnit (or Capnit), *Breith.*, Handb., 241, 236, 1841. Herrerite *Del Rio* is Smithsonite *F. A. Genth*, Proc. Ac. Sci. Philad., vii. 232. Dry-bone *Miners.*

Rhombohedral. $R \wedge R = 107° \ 40'$, $O \wedge R = 137° \ 3'$; $a = 0·8062$. Observed planes: O; rhombohedrons, R, 4, $-\frac{1}{2}$, -2, $-\frac{7}{2}$, -5; scalenohedron 1^3; prism i-2. $\frac{1}{2} \wedge \frac{1}{2} = 137° \ 7'$, $2 \wedge 2 = 80° \ 33'$, $\frac{7}{2} \wedge \frac{7}{2} = 68° \ 14'$, $5 \wedge 5 = 64° \ 17'$, $O \wedge \frac{1}{2} = 155° \ 2'$. R generally curved and rough. Cleavage: R perfect. Also reniform, botryoidal, or stalactitic, and in crystalline incrustations; also granular, and sometimes impalpable, occasionally earthy and friable.

H.=5. G.=4—4·45; 4·45, Levy; 4·42, Haidinger. Lustre vitreous, inclining to pearly. Streak white. Color white, often grayish, greenish, brownish-white, sometimes green and brown. Subtransparent—translucent. Fracture uneven—imperfectly conchoidal. Brittle.

Comp., Var.—$\dot{Z}n\ddot{C}$=Carbonic acid 35·2, oxyd of zinc 64·8=100; but part of the protoxyd of zinc often replaced by that of iron or manganese, and by traces of lime, magnesia; sometimes by oxyd of cadmium (anal. 9).

Varieties.—(1) *Ordinary.* (*a*) *Crystallized;* (*b*) *botryoidal* and *stalactitic*, common; (*c*) *granular* to *compact massive;* (*d*) *earthy*, impure, in nodular and cavernous masses, varying from grayish-white to dark gray, brown, brownish-red, brownish-black, and often with drusy surfaces in the cavities; "dry-bone" of American miners.

VAR. *depending on Composition.* (1) Containing less than 5 p. c. of any other carbonate, and without copper; anal. 1–10.

(2) *Ferriferous* (Zinkeisenspath), containing over 20 p. c. of carbonate of iron; *capnite* Breith., having $R \wedge R = 107° \ 7'$, Breith.; anal. 11–20.

(3) *Manganiferous*, containing over 5 p. c. of carbonate of manganese; G.=3·95—4·2; anal. 21–24.

(4) *Cupriferous*, *Herrerite* of Del Rio, apple-green, with rhombohedral cleavage; anal. 25. There are no lines of strong demarcation between these varieties based on composition.

Analyses: 1, 2, Smithson (Nicholson's J., vi. 76); 3, Heidingsfeld (Ramm. 5th Suppl.); 4, Schmidt (J. pr. Ch., li. 257); 5, Elderhorst (G. Rep. Arkansas, 153, 1858); 6, 7, H. Risse (Verh. nat. Ver. But a part of the 24 analyses of Altenberg smithsonite by H. Risse are given above. He writes the formula nŻn C̈+m(Ḟe, Ṁn, Ṁg, Ċa) C̈. The ratio of the 1st to the 2d member in anal. 16 (above) is 7 : 1; in 17, 5 : 1; in 19, 3 : 1; in 20, 2 : 1.

Pyr., etc.—In the closed tube loses carbonic acid, and, if pure, is yellow while hot and colorless on cooling. B.B. infusible; moistened with cobalt solution and heated in O.F. gives a green color on cooling. With soda on charcoal gives zinc vapors, and coats the coal yellow while hot, becoming white on cooling; this coating. moistened with cobalt solution, gives a green color after heating in O.F. Cadmiferous varieties, when treated with soda, give at first a deep yellow or brown coating before the zinc coating appears. With the fluxes some varieties react for iron, copper, and manganese. Soluble in muriatic acid with effervescence.

Obs.—Smithsonite is found both in veins and beds, especially in company with galenite and blende; also with copper and iron ores. It usually occurs in calcareous rocks, and is generally associated with calamine, and sometimes with limonite. It is often produced by the action of sulphate of zinc upon carbonate of lime or magnesia.

Found at Nertschinsk in Siberia, one variety of a dark brown color, containing cadmium, another of a beautiful bright green; at Dognatzka in Hungary; Bleiberg and Raibel in Carinthia; Wiesloch in Baden, in Triassic limestone; Moresnet in Belgium; Altenberg, near Aix la Chapelle (Aachen), in concentric botryoidal groups. In the province of Santander, Spain, between the Bay of Biscay and the continuation of the Pyrenees range, at Puente Viesgo, the mountains being only four leagues from the coast; the smithsonite here occurs in mountain limestone; in other places it is found in dolomite, probably muschelkalk; it is in vertical lodes, found frequently in scalenohedrons as a pseudomorph after calcite. At Ciguenza, 5 miles E. of Santander, the lode varies in width from 1 to 2 meters to 1 inch; the mineral is drusy, cavernous; blende is abundant, and changes into pure white smithsonite; the latter also occurs like chalcedony, in reniform and botryoidal masses; it sometimes contains galena and cerussite. In England, at Roughten Gill, Alston Moor, near Matlock, in the Mendip Hills, and elsewhere; in Scotland, at Leadhills; in Ireland, at Donegal.

In the U. States, in *Conn.*, at Brookfield in very small quantities. In *N. Jersey*, at Mine Hill, near the Franklin furnace, only pulverulent from decomposition of zincite. In *Penn.*, at Lancaster abundant, and often in fine druses of crystals, also sometimes pseudomorphous after dolomite; at the Perkiomen lead mine; at the Ueberroth mine, near Bethlehem, in scalenohedrons, also an earthy variety abundant as an ore. In *Wisconsin*, at Mineral Point, Shullsburg, etc. constituting pseudomorphs after blende and calcite. In *Minnesota*, at Ewing's diggings, N.W. of

Dubuque, etc. In *Missouri* and *Arkansas*, along with the lead ores in Lower Silurian limestone.

Alt.—Smithsonite changes through the action of alkaline silicates to calamine ($\dot{Z}n^2 \dddot{S}i + \frac{1}{2} \dot{H}$) or becomes incrusted with silica and forms quartz pseudomorphs. It is also sometimes replaced by limonite or göthite. The concretionary variety from Spain has a nucleus of calamine.

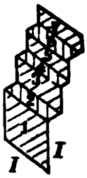
588F



bined about the acute angle, as the form consisting of *three* individuals, in f. 588B, a view of base, or section, the dotted lines showing the relations of the constituent parts; by extension of the combined crystals the form may be a hexagonal prism, either of simple juxtaposition or of penetration; also consisting of more than three individuals, 588C; (*b*) combined about the obtuse angle, as in f. 588D, which, by the extension of the parts, may become a hexagonal prism with or without reëntering angles; also in f. 588E, in which the three individuals extend across the middle, making a penetration twin, as illustrated by the numbering of the parts. The penetration or crossing twins often have the different parts very unequally developed (one or two of the three individuals extending across and not the other) and also of very unequal dimensions. Figures 588B to E are views of base of prism, showing the usual striæ parallel to the shorter diagonal; angle *m*=*r*=116° 10′, *n*=127° 40′, *s*=168° 30′. (3) Twinning often many times repeated in the same crystal, producing successive reversed layers, the alternate of which may be exceedingly thin, a structure illustrated in f. 588F; often so delicate as to produce by the succession a fine striation of the faces of a prism or of a cleavage plane.

Also globular, reniform, and coralloidal shapes; sometimes columnar, composed of straight or divergent fibres; also stalactitic; incrusting.

H.=3·5—4. G.=2·931, Haidinger; 2·927, Biot; 2·945—2·947, small crystals, and others when pulverized, Beudant; 2·932, fr. Kammsdorf, Schmid. Lustre vitreous, sometimes inclining to resinous on surfaces of fracture. Color white; also gray, yellow, green, and violet; streak uncolored. Transparent—translucent. Fracture subconchoidal. Brittle.

Var.—1. *Ordinary.* (*a*) Crystallized in simple or compound crystals, the latter much the most common; often in radiating groups of acicular crystals. (*b*) Columnar; a fine fibrous variety with silky lustre is called *Satin spar.* (*c*) Massive.

2. *Scaly massive;* snow-white (*Schaumkalk*); G.=2·984; from Wiederstadt, a pseudomorph after gypsum.

3. *Stalactitic* or *stalagmitic* (either compact or fibrous in structure); as with calcite; *Sprudelstein* is stalactitic from Carlsbad.

4. *Coralloidal;* in groupings of delicate interlacing and coalescing stems, of a snow-white color, and looking a little like coral.

5. *Tarnovicite;* a kind containing carbonate of lead, from Tarnowitz in Silesia; it has $I \wedge I = 116° 13'$, and $O \wedge 1\text{-}\bar{\imath} = 144° 15'$, Websky.

Mossottite is a light green, columnar, radiated variety, from the Lias of Gerfalco, in Tuscany, containing nearly 7 p. c. of carbonate of strontian and a trace of copper; G.=2·884. *Oserskite* is only columnar aragonite from Nertschinsk, Siberia; G.=2·854—2·855.

Slender crystals from Gross-Kammsdorf, near Saalfeld, owe their tapering form to the planes $9\text{-}\bar{\imath}$, 6, and 9 (Schmid, Pogg., cxxvi. 147). Figs. 583, 585, 588 are from Naumann.

Comp.—$\dot{C}a\ddot{C}$, like calcite,=Carbonic acid 44, lime 56=100. Analyses: 1–4, Stromeyer (De Arag.; also Schw. J., xiii. 362, 490, Gilb. Ann., xliii. xlv. xlvii. xlix. li. liv. lxiii.); 5, 6, Nendtwich (Versamml. ung. Naturf. Neusohl, 1846); 7, Böttger (Pogg., xlvii. 497); 8, Stieren (Arch. Pharm., II. lxii. 31); 9, Winkler (B. H. Ztg., xxiv. 819):

	$\dot{C}a\ddot{C}$	$\dot{S}r\ddot{C}$	$\dot{P}b\ddot{C}$	$\dot{H}$	$\overline{F}e^2\dot{H}^3$	
1. Brisgau	97·0963	2·4609	——	0·4102	——	=99·9674 Stromeyer.
2. Nertschinsk	97·9834	1·0933	——	0·2578	——	=99·3345 Stromeyer.
3. Eschwege	96·1841	2·2390	——	0·3077	0·2207	=98·9515 Stromeyer.
4. Aussig	98·00	1·0145	——	0·2139	0·1449	=99·3733 Stromeyer.
5. Herrengrund	98·62	0·99	——	0·17	$\overline{F}e$ 0·11	=99·89 Nendtwich.
6. Retzbanya	99·31	0·06	——	0·33	$\dot{C}u\ddot{C}$ 0·19	=99·89 Nendtwich.
7. *Tarnowitzite*	95·940	——	3·859	0·157	——	=99·956 Böttger.
8. Papenberg	97·89	2·22	——	——	——	=$\dot{H}$ 0·39=100 Stieren.
9. Alston-Moor	97·35	——	——	——	——	, $\dot{M}g\ddot{C}$ 2·49, Ca F *tr.*=99·84 W.

Delesse finds in the aragonite of Herrengrund, near Neusohl, Hungary, no strontia, and 0·13 p. c. of water. A Thurnberg variety afforded E. Riegel (Jahrb. pr. Pharm., xxiii. 348), 2·2 p. c. of carbonate of strontian. A fibrous variety from Dufton in Cumberland afforded 4·25 p. c. of $\dot{M}n\ddot{C}$.

Kersten detected 2·19 p. c. of carbonate of lead in one specimen. The *Sprudelstein* of Carlsbad contains 0·69 p. c. of fluorid of calcium and 0·27 of arsenic. Jenzsch reports most aragonites as containing fluorine, and finds in one of unknown locality Ca F 3·27, $\dot{C}a^3\dddot{P}$ 1·24 p. c.; G.=2·830.

Luca gives for the *Mossottite* (l. c.) $\ddot{C}$ 41·43, $\dot{C}a$ 50·08, $\dot{S}r$ 4 69, $\dot{C}u$ 0·95, $\overline{F}e$ 0·82, F *tr.*, $\dot{H}$ 1·36=99·33. Plattner found only carbonate of lime in the oserskite.

Aragonite and calcite were the first case of dimorphism observed. Kirwan suggested in 1794 that the prismatic form was due to the presence of strontia, which Stromeyer disproved in 1813.

Pyr., etc.—B.B. whitens and falls to pieces, and sometimes, when containing strontia, imparts a more intensely red color to the flame than lime; otherwise reacts like calcite.

Obs.—The most common repositories of aragonite are beds of gypsum, beds of iron ore (where it occurs in coralloidal forms, and is denominated *flos-ferri*, "*flower of iron*"), basalt, and trap rock; occasionally it occurs in lavas. It is often associated with copper and iron pyrites, galenite, and malachite. It is forming at an old mine in Monte Vasa, Italy, at a temperature below the boiling point of water. It constitutes the pearly layer of shells. Minute pointed crystals occur in drusy cavities in the sinter of the thermal springs of Baden.

First discovered in Aragon, Spain (whence its name, the word in Spain having but one *r*), at Molina and Valencia, near Migranilla, in six-sided prisms, with gypsum, imbedded in a ferruginous clay. Since found at Bilin in Bohemia, in a vein traversing basalt in fine prisms; at Breisgau in Baden; at Baumgarten and Tarnowitz in Silesia; at Leogang in Salzburg, Austria; in Waltsch, Bohemia, and many other places. The *flos-ferri* variety is found in great perfection in the Styrian mines, coating cavities and even caves of considerable extent, and associated with spathic iron. At Dufton, a silky, fibrous variety, called *satin spar*, occurs traversing shale in thin veins, generally associated with pyrite. In Buckinghamshire, Devonshire, etc., it occurs in stalactitic forms in caverns, and of snowy whiteness at Leadhills in Lanarkshire.

Aragonite in fibrous crusts and other forms occurs in serpentine at Hoboken, N. J. (it has been called magnesite). Coralloidal aragonite occurs sparingly at Lockport, N. Y., coating gypsum in geodes; at Edenville, N. Y., lining cavities of arsenopyrite and cube ore; at the Parish ore bed, Rossie, N. Y.; at Haddam, Conn., in thin seams between layers of gneiss; at New Garden in Chester Co., Penn.; at Wood's Mine, Lancaster Co., Penn.; at Warsaw, Ill., lining geodes; on the north boundary of the Creek nation, 16 m. from the crossing of the Arkansas, in hexagonal crystals nearly ¼ in. through.

Alt.—Aragonite may undergo similar changes with calcite. It also passes to calcite, through paramorphism. Pseudomorphs of copper after aragonite are reported from Bolivia, and also from Corocoro, Peru.

725. MANGANOCALCITE. Manganocalcit *Breith.*, Pogg., lxix. 429, 1846. Fasriger Braunspath *Wern.*

In rhombic prisms like aragonite, and closely related to that species. Cleavage lateral, also brachydiagonal. Radiated fibrous or columnar.

H.=4—5. G.=3·037. Lustre vitreous. Flesh-red to dull reddish-white. Streak colorless. Translucent.

Comp.—2 $\dot{M}n\,\ddot{C}+(\dot{C}a, \dot{M}g)\,\ddot{C}$, with a little of the manganese replaced by iron; or of the general formula $\dot{R}\,\ddot{C}$. Analyses: 1, Rammelsberg (Pogg., lxviii. 511); 2, Missoudakis (Jahrb. Min. 1846, 614):

	$\dot{M}n\,\ddot{C}$	$\dot{F}e\,\ddot{C}$	$\dot{M}g\,\ddot{C}$	$\dot{C}a\,\ddot{C}$	
1.	67·48	3·22	9·97	18·81=99·48	Ramm.
2.	77·98	3·31	——	18·71=100	Missoudakis.

Pyr., etc.—Same as for rhodochrosite.

Obs.—From Schemnitz in Hungary, with quartz, blende, galenite, etc.

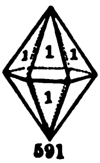
THOMAITE Mayer (Jahrb. Min. 1845, 200). A carbonate of iron, occurring in pyramidal crystallizations which are said to be orthorhombic; also massive. G.=3·10. Lustre pearly. An analysis by Meyer afforded $\ddot{C}$ 38·39, $\dot{F}e$ 53·72, $\dot{M}n$ 0·65, $\dot{M}g$ 0·48, $\dot{C}a$ 1·52, $\ddot{\bar{A}}l$ 4·25, $\dddot{S}i$ 6·04=100. From Bleis-Bach, in Siebengebirge. Named after Prof. Thomă of Wiesbaden.

Junckerite of Dufrénoy was described as having the same characters, but proved to be only common spathic iron; and the same fate may befall thomaite.

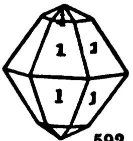
726. WITHERITE. Terra ponderosa aerata *Withering*, Trl. Bergm. Sciagr., 29, 1783, Phil. Trans., 298, 1784. Witherit *Wern.*, Bergm. J., 1790, ii. 225. Aerated Barytes *Watt*, Mem. Manchester Soc., iii. 599, 1790. Barolite *Kirwan*, Min., i. 134, 1794. Kohlensaurer Baryt *Germ.* Baryte carbonatée *Fr.*

Orthorhombic. $I \wedge I=118°\ 30'$, $O \wedge 1\text{-}\bar{i}=128°\ 45'$; $a : b : c=1·246 :$

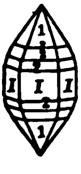
589



590

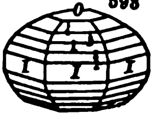


591

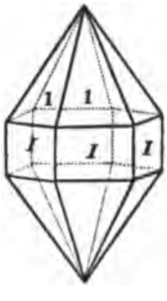


592

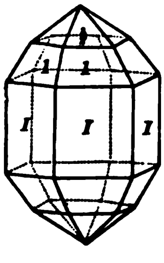
593



594



595



1 : 1·6808. Observed planes, I, ¼, ½, 1, $\frac{3}{2}$, 2. $O \wedge 1=124°\ 35\frac{1}{2}'$, $I \wedge 1=145°\ 24\frac{1}{2}'$, $I \wedge 2=160°\ 58\frac{1}{2}'$, $I \wedge \frac{3}{2}=155°\ 18\frac{1}{2}'$, $I \wedge \frac{1}{2}=125°\ 57\frac{1}{2}'$, $I \wedge \frac{1}{4}=$

109° 55½′, 1 ∧ 1, mac.,=130° 13′, brach., 89° 57′, bas., 110° 49′. Twins: all the annexed figures, composition parallel to *I*; reëntering angles sometimes observed. Cleavage: *I* distinct; also in globular, tuberose, and botryoidal forms; structure either columnar or granular; also amorphous.

H.=3—3·75. G.=4·29—4·35. Lustre vitreous, inclining to resinous, on surfaces of fracture. Color white, often yellowish, or grayish. Streak white. Subtransparent—translucent. Fracture uneven. Brittle.

Comp.—$\dot{\mathrm{Ba}}\,\ddot{\mathrm{C}}$=Carbonic acid 22·3, baryta 77·7=100. Analyses of the Anglezarke mineral: Klaproth (Beitr., i. 260, ii. 84) obtained $\ddot{\mathrm{C}}$ 22, $\dot{\mathrm{Ba}}$ 78; Withering (l. c.), $\ddot{\mathrm{C}}$ 21·4, $\dot{\mathrm{Ba}}$ 78·6.

Thomson's *Sulphato-carbonate of Baryta* (Rec. Gen. Sci., i. 375, 1835, and Min., i. 106) is witherite incrusted by barite, as shown by Heddle (Phil. Mag., IV. xiii. 537), who analyzed specimens from Hexham in Northumberland, and Dufton Fells in Westmoreland.

Pyr., etc.—B.B. fuses at 2 to a bead, coloring the flame yellowish green; after fusion reacts alkaline. B.B. on charcoal with soda fuses easily, and is absorbed by the coal. Soluble in dilute muriatic acid; this solution, even when very much diluted, gives with sulphuric acid a white precipitate which is insoluble in acids.

Obs.—Occurs at Alston-Moor in Cumberland, associated with galenite, in veins traversing the coal formation; at Fallowfield near Hexham in Northumberland, in splendid crystals, sometimes transparent, and occasionally 6 in. long; at Anglezarke in Lancashire, a fibrous variety; at Arkendale in Yorkshire; near St. Asaph in Flintshire; Tarnowitz in Silesia; Szlana, Hungary; Leogang in Salzburg; Peggau in Styria; Zméoff in the Altai; some places in Sicily; the mine of Arqueros, near Coquimbo, Chili; L. Etang Island; near Lexington, Ky., with barite.

Witherite is extensively mined at Fallowfield, and is used in chemical works in the manufacture of plate-glass, and in France in making beet-sugar.

Alt.—Witherite is altered to barite ($\dot{\mathrm{Ba}}\,\dddot{\mathrm{S}}$) through the action of sulphate of lime in solution at the ordinary temperature, or by the action of other sulphates in solution, or of water containing sulphuric acid.

727. BROMLITE. Barytocalcite *J. F. W. Johnson*, Phil. Mag., III. vi. 1, 1835, x. 373, 1837. Bicalcareo-carbonate of Barytes (from a wrong anal.) *Thomson*, Rec. Gen. Sci., i. 373, 1835. Bromlite *Thoms.*, Phil. Mag., xi. 45, 48, 1837. Alstonite *Breith.*, Handb., ii. 255, 1841.

Orthorhombic. *I* ∧ *I*=118° 50′, Descl., *O* ∧ 1-ī=128° 39′; *a* : *b* : *c*= 1·2504 : 1 : 1·6920. Observed planes: *O*; prism, *I*; octahedrons, 1, ½; domes, 1-ĭ, 2-ĭ. *O* ∧ 1-ĭ=143° 32½′, 1-ĭ ∧ 1-ĭ, bas.,=72° 55′, 2-ĭ ∧ 2-ĭ, bas., =111° 50′, 1 ∧ 1, mac.,=130° 27′, 1 ∧ 1, brach.,=89° 40′. Twins: double six-sided pyramids, with angles 122° 30′, and 142°; reëntering angle 178° 51′. Cleavage: *I* and *O* rather indistinct.

H.=4—4·5. G.=3·718, Thomson; 3·706, Johnston. Lustre vitreous. Colorless, snow-white, grayish, pale cream-color, pink. Translucent. Fracture granular and uneven.

Comp.—$\dot{\mathrm{Ba}}\,\ddot{\mathrm{C}}+\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$, like barytocalcite=Carb. baryta 66·3, carb. lime 33·7=100.

Analyses: 1, Johnston (l. c.); 2, Thomson (Phil. Mag., xi. 45); 3, Delesse (Ann. Ch. Phys., III. xiii. 425); 4, v. Hauer (Ber. Ak. Wien, iv. 332, 1853):

	$\dot{\mathrm{Ba}}\,\ddot{\mathrm{C}}$	$\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$	$\dot{\mathrm{Sr}}\,\ddot{\mathrm{C}}$	$\dot{\mathrm{Mn}}\,\ddot{\mathrm{C}}$
1. Bromley	62·16	30·29	6·64	——=99·9 Johnston.
2. Fallowfield	50·63	30·19	——	9·18=100 Thomson.
3. "	65·31	32·90	1·10	——, $\dddot{\mathrm{Si}}$ 0·20, $\dot{\mathrm{Mn}}$ 0·16=99·67 Delesse.
4. "	65·71	34·29	——	——, $\dddot{\mathrm{Si}}$ *tr.*=100 Hauer.

Pyr., etc.—Same as in barytocalcite.

Obs.—Found at the lead mine of Fallowfield, near Hexham in Northumberland, with witherite and at Bromley Hill near Alston in Cumberland, in veins with galenite, whence the name *Bromlite*, given by Thomson. Most English mineralogical authors have set aside Thomson's name although the earliest and of British origin, for Breithaupt's. There appears to be no sufficient reason for this.

728. STRONTIANITE. Strontianit *Sulzer*, Lichtenberg's Mag., vii. 3, 68, Bergm. J., 1791, i. 5, 433. Strontian *Wern.* Strontianit, Kohlensaure Strontianerde, *Klapr.*, Crell's Ann., 1793, ii. 189; 1794, i. 99; Beitr., i. 268. Mineral from Strontian, Strontian Spar (*not* Strontites=Strontia), *Hope*, Edinb. Trans., iv. 3, 1798 (Art. read Nov., 1793). Carbonate of Strontian. Strontiane carbonateé *Fr.*

Emmonite, Calcareo-carbonate of Strontian, *Thomson*, Rec. Gen. Sci., iii. 415, 1836. Barystrontianite, Stromnite, *S. Traill*, Ed. Phil. J., i. 380, 1819.

Orthorhombic. $I \wedge I = 117° 19'$, $O \wedge 1\text{-}\bar{i} = 130° 5'$; $a : b : c = 1{\cdot}1883 : 1 : 1{\cdot}6421$. Observed planes: octahedrons, $\frac{1}{2}$, $\frac{4}{5}$, 1, $\frac{4}{3}$, 2, 3, 4, 8; domes, $\frac{1}{2}\text{-}\bar{i}$, $1\text{-}\bar{i}$, $\frac{3}{4}\text{-}\breve{i}$, $2\text{-}\breve{i}$, $4\text{-}\breve{i}$, $6\text{-}\breve{i}$, $8\text{-}\bar{i}$, $12\text{-}\bar{i}$.

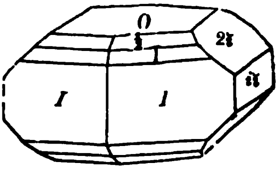
$O \wedge \frac{1}{2}\text{-}\bar{i} = 149° 17'$
$O \wedge \frac{1}{2} = 145\ 11$
$O \wedge 1 = 125\ 43$

$O \wedge 1\text{-}\breve{i} = 144° 6'$
$1\text{-}\bar{i} \wedge 1\text{-}\bar{i}$, bas., $= 71\ 48$
$2\text{-}\breve{i} \wedge 2\text{-}\breve{i}$, bas., $= 110\ 44$

$1 \wedge 1$, mac., $= 130° 1'$
$1 \wedge 1$, brach., $= 92\ 11$
$1 \wedge 1$, bas., $= 108\ 35$

Cleavage: I nearly perfect, $i\text{-}\breve{i}$ in traces. Crystals often acicular and in divergent groups. Twins: like those of aragonite. O usually striated parallel to the shorter diagonal. Also in columnar globular forms; fibrous and granular.

596



H.=3·5–4. G.=3·605–3·713. Lustre vitreous; inclining to resinous on uneven faces of fracture. Color pale asparagus-green, apple-green; also white, gray, yellow, and yellowish-brown. Streak white. Transparent—translucent. Fracture uneven. Brittle.

Comp.—Carbonate of Strontia, $\dot{Sr}\ddot{C}$=Carbonic acid 29·8, strontia 70·2; but a small part of the strontia often replaced by lime.

Analyses: 1, Klaproth (Beitr., i. 270, ii. 84); 2, Stromeyer (Unters., i. 193); 3, Thomson (Min., i. 108); 4, Stromeyer (l. c.); 5, Jordan (Schw. J., lvii. 344); 6, Redicker (Pogg., l. 191); 7, Schnabel (Ramm. 5th Suppl.); 8, Von der Mark (Verh. nat. Ver. Bonn, vi., Jahrg., 272):

	$\ddot{C}$	$\dot{Sr}$	$\dot{Ca}$	$\cancel{F}e$	$\cancel{M}n$	$\dot{H}$
1. Strontian.	30·0	69·5	——	——	——	0·5=100 Klapr.
2. "	30·31	65·60	3·47	0·07		0·07=99·52 Strom.
3. "	30·66	65·53	3·52	0·01	——	——=99·72 Thomson.
4. Bräunsdorf, Sax.	29·94	67·52	1·28	——	0·09	0·07=98·90 Strom.
5. Clausthal, *white*	30·59	65·14	3·64	——	——	0·25=99·62 Jordan.
6. Hamm, Westph.	30·80	65·30	3·82	——	——	0·08=100 Redicker.
7. " "	30·86	64·32	4·42	——	——	——=99·60 Schnabel.
8. " "	30·84	63·57	4·80	——	——	——=99·21 Mark.

Thomson obtained in his *emmonite* (l. c.) $\dot{Sr}\ddot{C}$ 82·69, $\dot{Ca}\ddot{C}$ 12·50, $\cancel{F}e$ 1·00, zeolite 3·79=99·98. Traill's *stromnite* afforded him $\dot{Sr}\ddot{C}$ 68·6, $\dot{Ba}\dddot{S}$ (barite) 27·5, $\dot{Ca}\ddot{C}$ 2·6, oxyd of iron 0·1; color grayish-white; G.=3·703. It is pronounced a mixture by Greg and Lettsom. It is from near Stromness, on Pomona, one of the Orkneys.

Pyr., etc.—B.B. swells up, throws out minute sprouts, fuses only on the thin edges, and colors the flame strontia-red; the assay reacts alkaline after ignition. Moistened with muriatic acid and treated either B.B. or in the naked lamp gives an intense red color. With soda on charcoal the pure mineral fuses to a clear glass, and is entirely absorbed by the coal; if lime or iron be present they are separated and remain on the surface of the coal. Soluble in muriatic acid; the dilute solution when treated with sulphuric acid gives a white precipitate.

Obs.—Occurs at Strontian in Argyleshire, in veins traversing gneiss, along with galenite and barite, in acicular diverging and fibrous groups, rarely in perfect crystals; in Yorkshire, England; Giant's Causeway, Ireland; Clausthal in the Harz; Bräunsdorf, Saxony; Leogang in Saltzburg

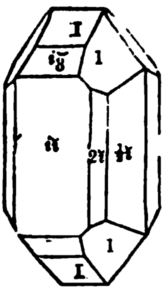
In the U. States it occurs at Schoharie, N. Y., in granular and columnar masses, and also in crystals, forming nests or geodes, often large, in the hydraulic limestone, associated with barite pyrite, and calcite. At Muscalongo Lake a massive and fibrous variety, of a white or greenish white color, is sometimes the matrix of fluorite. Chaumont Bay and Theresa, in Jefferson Co. N. Y., are other localities.

Alt.—Strontianite is altered to celestite in the same way as witherite to barite.

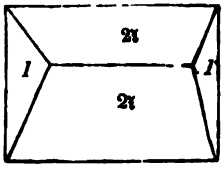
729. CERUSSITE. Ψιμύθιον *Theophr.*, etc., Cerussa *Plin.*, etc., *Agric.*, but only the artificial Cerussa nativa ex agro Vicentino *Gesner*, Foss., 85, 1565. Cerussit *Haid.*, Handb., 503, 1845. Iglésiasite (Zinc-Bleispath *Kersten*) *Huot*, Min., 618, 1841.

Orthorhombic. $I \wedge I=117°\ 13'$, $O \wedge 1\text{-}\bar{\imath}=130°\ 9\frac{1}{2}'$; $a : b : c=1{\cdot}1852 : 1 : 1{\cdot}6388$. Observed planes: O; vertical, I, $i\text{-}\breve{\imath}$, $i\text{-}\bar{\imath}$, $i\text{-}\breve{3}$, $1\text{-}\bar{\frac{3}{2}}$; domes, $\frac{1}{3}\text{-}\bar{\imath}$, $\frac{1}{2}\text{-}\bar{\imath}$, $1\text{-}\bar{\imath}$, $2\text{-}\bar{\imath}$; $\frac{1}{3}\text{-}\breve{\imath}$, $\frac{1}{2}\text{-}\breve{\imath}$, $1\text{-}\breve{\imath}$, $2\text{-}\breve{\imath}$, $3\text{-}\breve{\imath}$, $4\text{-}\breve{\imath}$; octahedral, $\frac{1}{3}$, $\frac{1}{2}$, 1; $2\text{-}\breve{2}$, $2\text{-}\bar{2}$, $1\text{-}\bar{2}$, $1\text{-}\breve{3}$.

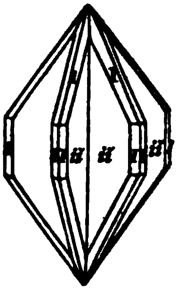
597



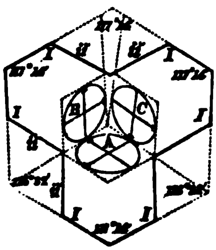
598



599



600



$O \wedge 1=125°\ 46'$
$O \wedge \frac{1}{2}\text{-}\bar{\imath}=149\ 21$
$O \wedge 1\text{-}\breve{\imath}=144\ 8$
$O \wedge 2\text{-}\breve{\imath}=124\ 40$
$I \wedge i\text{-}\breve{\imath}=121\ 24$
$i\text{-}\breve{\imath} \wedge 2\text{-}\breve{\imath}=145\ 20$
$i\text{-}\breve{\imath} \wedge \frac{1}{2}\text{-}\breve{\imath}=109\ 53$

$2\text{-}\breve{\imath} \wedge 2\text{-}\breve{\imath}$, bas.,$=110°\ 40'$
$1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath}$, bas.,$=71\ 44$
$\frac{1}{2}\text{-}\breve{\imath} \wedge \frac{1}{2}\text{-}\breve{\imath}$, bas.,$=39\ 45$
$i\text{-}\breve{3} \wedge i\text{-}\breve{3}$, ov. $i\text{-}\breve{\imath}$,$=122\ 43$
$1 \wedge 1$, mac.,$=130$
$1 \wedge 1$, brach.,$=92\ 19$
$1 \wedge 1$, bas.,$=108\ 28$

Cleavage: I often imperfect; $2\text{-}\breve{\imath}$ hardly less so. Crystals usually thin, broad, and brittle; sometimes stout. Twins: very common; composition face I, producing usually cruciform or stellate forms. 1. Consisting of two individuals; (*a*) similar to f. 584 under aragonite, p. 694, or to f. 600 if the left of the three rays were wanting; (*b*) cruciform, similar in mode of intersection to f. 586, 587, p. 695. 2. Consisting of more than two individuals; (*a*) three-rayed, f. 600, a view of a section, showing at centre the position of the three combined crystals; (*b*) six-rayed, f. 599, which may consist, like the last, of three combined crystals, if the crystals cross at centre so as to make a penetration-twin; the forms sometimes thin, as in f. 599, but often consisting of stout crystals similar in form to f. 597, the planes *I* in this form having the same position as *I*, *I* in f. 599.

Rarely fibrous, often granular massive and compact. Sometimes stalactitic.

H.=3–3·5. G.=6·465–6·480; some earthy varieties as low as 5·4. Lustre adamantine, inclining to vitreous or resinous; sometimes pearly; sometimes submetallic, if the colors are dark, or from a superficial change. Color white, gray, grayish-black, sometimes tinged blue or green by some of the salts of copper; streak uncolored. Transparent—subtranslucent. Fracture conchoidal. Very brittle.

Comp.—$\dot{Pb}\,\ddot{C}$=Carbonic acid 16·5, oxyd of lead 83·5=100. Analyses: 1, Westrumb (l. c.); 2, Klaproth (Beitr., iii. 167); 3, J. A. Phillips (Q. J. Ch. Soc., iv. 175); 4, Bergemann (Chem. Unters. Bleib., 167, 175); 5, J. L. Smith (Am. J. Sci., II. xx. 245):

5. Phenixville, Pa.	16·38	83·76=100·14 Smith.

Stalactites from Brigham's diggings, Wis., afforded J. D. Whitney (Upp. Miss. Rep., 291, 1862) Carbonate of lead 93·84, of lime 0·18, of magnesia *tr.*, sesquioxyd of iron, etc., 1·42, clay and sand 3·43=99·27. Kersten obtained for the *iglesiasite* (Schw. J., lxv. 365) $\dot{Pb}\,\ddot{C}$ 92·10, $\dot{Zn}\,\ddot{C}$ 7·02=99·12=6 $\dot{Pb}\,\ddot{C}+\dot{Zn}\,\ddot{C}$.

Pyr., etc.—In the closed tube decrepitates, loses carbonic acid, turns first yellow, and at a higher temperature dark red, but becomes again yellow on cooling. B.B. on charcoal fuses very easily, and in R.F. yields metallic lead. Soluble in dilute nitric acid with effervescence.

Obs.—Occurs in connection with other lead minerals, and is formed from galenite (sulphid of lead), which, as it passes to a sulphate, may be changed to carbonate by means of solutions of bicarbonate of lime. It is found at Johanngeorgenstadt in beautiful crystals; at Nertschinsk and Beresof in Siberia; near Bonn on the Rhine; at Clausthal in the Harz; at Bleiberg in Carinthia; at Mies and Przibram in Bohemia; at Retzbanya, Hungary; in England, in Cornwall, in the mine of St Minvers; delicate crystals 10 in. long were formerly found near St. Austell and elsewhere; at E. Tamar mine, Devonshire; near Matlock and Wirksworth, Derbyshire; in Cardiganshire, Wales; at Leadhills and Wanlockhead. Scotland, formerly in fine crystals; in Wicklow, Ireland, magnificent, sometimes in heart-shaped macles. In pseudomorphs, imitating anglesite and leadhillite, at Leadhills.

Found in *Mass.*, sparingly at the Southampton lead mine. In *Penn.*, at Phenixville, in fine crystals, often large; also good at Perkiomen. In *N. York*, at the Rossie lead mine, but rare. In *Virginia*, good crystals at Austin's mines, Wythe Co. In *N. Carolina*, at King's mine, Davidson Co., good. At Valle's diggings, Mo., but seldom crystallized; in Wisconsin and other lead mines of the northwestern States, rarely in crystals; near the Blue Mounds, Wis., at Brigham's diggings, in stalactites.

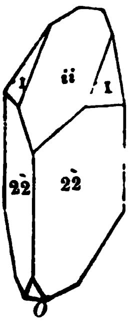
Alt.—Cerussite occurs altered to pyromorphite, or phosphate of lead; probably through the action of waters holding phosphate of lime in solution; also to galenite (Pb S) through the action of sulphuretted hydrogen, and minium by oxydation; also to breunerite, malachite, and chrysocolla.

---

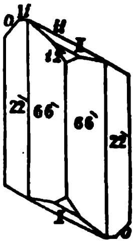
730. BARYTOCALCITE. *Brooke*, Ann. Phil., II. viii. 114, 1824.

Monoclinic. $C=73°\ 52'$, $I \wedge I=106°\ 54'$, $O \wedge 1\text{-}\grave{i}=149°$; $a:b:c=$ 0·81035 : 1 : 1·29583. $O \wedge 1\text{-}i=147°\ 34'$, $O \wedge i\text{-}i=106°\ 8'$, $i\text{-}i \wedge 1\text{-}i=138°\ 34'$, $i\text{-}\grave{i} \wedge i\text{-}\grave{2}=124°$, $2\text{-}\grave{2} \wedge 2\text{-}\grave{2}$, over $6\text{-}\grave{6}$, $=95°\ 8'$, $6\text{-}\grave{6} \wedge 6\text{-}\grave{6}$, adj., $=146°\ 6'$. Cleavage: *I*, perfect; *O*, less perfect; also massive.

603



604



H.=4. G.=3·6363—3·66. Lustre vitreous, inclining to resinous Color white grayish, greenish, or yellowish. Streak white. Transparent—translucent. Fracture uneven.

Comp.—$\dot{B}a\ddot{C}+\dot{C}a\ddot{C}=(\frac{1}{2}\dot{B}a+\frac{1}{2}\dot{C}a)\ddot{C}$=Carbonate of baryta 66·3, carbonate of lime 33·7=100. Analyses: 1, Children (Ann. Phil, viii. 115); 2, Delesse (Ann. Ch. Pharm., III. xiii. 425):

	$\dot{B}a\ddot{C}$	$\dot{C}a\ddot{C}$	$\dddot{Si}$
1.	65·9	33·6	——=99·5 Children.
2.	66·20	31·89	0·27=98·36 Delesse.

Pyr., etc.—B.B. colors the flame yellowish-green, and at a high temperature fuses on the thin edges and assumes a pale green color (manganate of baryta, Plattner); the assay reacts alkaline after ignition. With the fluxes reacts for manganese. With soda on charcoal the lime is separated as an infusible mass, while the remainder is absorbed by the coal. Soluble in dilute muriatic acid.

Obs.—Occurs at Alston-Moor in Cumberland, in attached crystals and massive, in the Subcarboniferous or mountain limestone. Fig. 604 is from Brooke and Miller. Crystals 2 in. long have been obtained.

731. PARISITE. Musite *Medici-Spada*, 1835. Parisit *Medici-Spada*, Bunsen, Ann. Ch. Pharm., liii. 147, 1845.

Hexagonal. In elongated double six-sided pyramids, with truncated apex; basal angle 164° 58′, pyramidal 120° 34′. Cleavage: basal, very perfect.

H.=4·5. G.=4·35, Bunsen; 4·317, Dufr. Vitreous; cleavage-face pearly or resinous. Color brownish-yellow; streak yellowish-white.

Comp.—$(\dot{C}e, \dot{L}a, \dot{D}i)\ddot{C}+\frac{1}{2}(Ca, Ce)F$; whence, making $\dot{C}e:\dot{L}a:\dot{D}i=4:1:1$, as in Damour & Deville's anal., the percentage is, carbonic acid 24·5, protoxyd of cerium 40·3, protoxyd of lanthanum 10·2, protoxyd of didymium 10·4, fluorid of calcium 14·6=100. These chemists show that the water found by Bunsen is accidental. Analyses: 1, 2, Bunsen (l. c.); 3, Damour & Deville (C. R., lix. 271):

	$\ddot{C}$	$\dot{C}e$	$\dot{L}a$	$\dot{D}i$	$\dot{C}a$	$\dot{H}$	CaF
		$\underbrace{\qquad\qquad\qquad}$					
1.	23·51		59·44		3·17	2·38	11·51
2.	23·64		60·26		3·15	2·42	10·53
3.	23·48	42·52	8·26	9·58	2·85	—	10·10, CeF 2·16, $\dot{M}n$ *tr.*=98·95 D. & D.

Pyr., etc.—In the closed tube yields no water, but gives off carbonic acid and becomes lighter in color. B.B. glows and is infusible. With fused salt of phosphorus in the open tube gives B.B. the reaction for fluorine. With borax and salt of phosphorus in the platinum loop gives a glass, yellow while hot and colorless on cooling. Dissolves slowly in muriatic acid with effervescence.

Obs.—From the emerald mines of the Muso valley, New Granada, where it was discovered by J. J. Paris, the proprietor of the mine, and from which place it was sent in 1835 to Medici-Spada, by Col. Acosta.

fter J. J. Paris. The earlier name *Musite* (sometimes written *Mussite*, the name of the written both Muso and Musso, as well as Muzo) is objectionable, because of the use *Mussite* for a variety of amphibole.

32. KISCHTIMITE. Kischtim-Parisit *T. Korovaeff*, Bull. Ac. St. Pet., iv. 401, 186 , J. pr Ch., lxxxv 442, 1862. Kischtimite *G. J. Brush*, Am. J. Sci., II. xxxv. 427, 1863.

Amorphous.

G =4·784. Lustre between greasy and vitreous. Color dark brownish yellow. Streak much lighter than color. In small pieces translucent. Friable.

Comp.—6 $\dot{L}a\ \ddot{C}+Ce^2O^3+Ce^2F^3+2\ \dot{H}$, or 3 $\dot{L}a\ \ddot{C}+Ce^2(F,O)^3+\dot{H}$, Korovaeff,=Carbonic acid 17·6, lanthana 37·7, cerium 25·2, fluorine 7·5, oxygen 9·6, water 2·4=100. The water is probably unessential, as in parisite. Analysis: Korovaeff (l. c.):

	$\ddot{C}$	La	Ce	F	O	$\dot{H}$
(½)	17·19	36·56	27·81	6·35	[9·89]	2·20

Pyr., etc.—B.B. at a moderate temperature becomes dull, opaque, and opaline yellow; at a high heat glows, and on cooling has a high lustre and is brick-red. With borax in the outer flame a yellow glass, in the inner faint yellow, which becomes colorless on cooling. The powder moistened with sulphuric acid gives off fluohydric acid. Dissolves in muriatic acid, evolving carbonic acid and chlorine.

Obs.—From the gold washings of the Borsovka river, in the district of Kischtim, Urals.

733. PHOSGENITE. Hornblei *Karst.*, Tab., 78, 1800. Salzsaures Bleierze *Klapr.*, Beitr., iii. 141, 1802. Corneous Lead. Sardinia.

Cleavage: *I* and *i-i* bright; also basal.

H.=2·75—3. G.=6—6·31. Lustre adamantine. Color white, gray, and yellow. Streak white. Transparent—translucent. Rather sectile.

Comp.—$\dot{P}b\ \ddot{C}+Pb\ Cl$=Carbonate of lead 49, chlorid of lead 51=100, or oxyd of lead 81·9, carbonic acid 8·1, chlorine 13·0=102·9.

Analyses: 1, Klaproth (Beitr., iii. 141, modernized); 2, Rammelsberg (Pogg., lxxxv. 141); 3, R. A. Smith (Phil. Mag., IV. ii. 121); 4, Krug v. Nidda (ZS. G., ii. 126):

	$\dot{P}b\ \ddot{C}$	Pb Cl
1. Cromford	48·4	53·5=101·9 Klaproth.
2. "	48·45	50·93=99·38 Ramm. G.=6·305.
3. "	48·22	51·78=100 Smith.
4. Tarnowitz	49·44	50·45=99·89 K. v. Nidda.

Pyr., etc.—B.B. melts readily to a yellow globule, which on cooling becomes white and crystalline. On charcoal in R.F. gives metallic lead, with a white coating of chlorid of lead. With a salt of phosphorus bead previously saturated with oxyd of copper gives the chlorine reaction. Dissolves with effervescence in nitric acid.

Obs.—At Cromford near Matlock in Derbyshire, where some of the crystals were 2 or 3 in long; very rare in Cornwall; in minute crystals at a lead mine near Elgin in Scotland, some crystals recently obtained at Cromford sold for 15 to 20 pounds sterling each; in large crystals at Gibbas (f. 605) and Monteponi in Sardinia; near Bobrek in Upper Silesia.

Recent paper on cryst., Kokscharof, Bull. Ac. St. Pet., ix. 231, 1865, from which the above figure and angles are taken.

II. HYDROUS CARBONATES.

ARRANGEMENT OF THE SPECIES.

I. Containing ammonia or soda.

735. TESCHEMACHERITE	$(\tfrac{1}{2}NH^4O+\tfrac{1}{2}HO)\ddot{C}$	$\Theta\,\Theta\vert\Theta_2\|(\tfrac{1}{2}Am_2+\tfrac{1}{2}H_2)$
736. NATRON	$\dot{Na}\ddot{C}+10\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert Na_2+10\,aq$
737. THERMONATRITE	$\dot{Na}\ddot{C}+\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert Na_2+aq$
738. TRONA	$(\tfrac{2}{3}\dot{Na}+\tfrac{1}{3}\dot{H})+\dot{H}$	$\Theta\,\Theta\vert\Theta_2\|(\tfrac{2}{3}Na_2+\tfrac{1}{3}H_2)+aq$
739. GAYLUSSITE	$(\tfrac{1}{2}\dot{Na}+\tfrac{1}{2}\dot{Ca})\ddot{C}+2\tfrac{1}{2}\dot{H}$	$\Theta\,\Theta\vert\Theta_2\|(\tfrac{1}{2}Na_2+\tfrac{1}{2}\Theta a)+2\tfrac{1}{2}\,aq$

II. Containing lime or magnesia.

740. HYDROMAGNESITE	$\dot{Mg}\ddot{C}+\tfrac{1}{3}\dot{Mg}\dot{H}+\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert Mg+\tfrac{1}{3}Mg\,H_2\Theta_2+aq$
741. HYDRODOLOMITE	$(\dot{Ca},\dot{Mg})\ddot{C}+\tfrac{1}{3}\dot{H}$	$\Theta\,\Theta\vert\Theta_2\|(\Theta a,Mg)+\tfrac{1}{3}\,aq$
742. PREDAZZITE	$\dot{Ca}\ddot{C}+\tfrac{1}{2}\dot{Mg}\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert\Theta a+\tfrac{1}{2}Mg\,H_2\Theta_2$
743. PENCATITE		
744. HOVITE	$(\tfrac{1}{2}\dot{Ca}+\tfrac{1}{2}\dot{H})\ddot{C}+aq$	$\Theta\,\Theta\vert\Theta_2\|(\tfrac{1}{2}\Theta a+\tfrac{1}{2}H_2)+aq$

III. Containing oxyd of cerium, lanthanum, or yttrium.

745. LANTHANITE	$\dot{La}\ddot{C}+3\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert La+3\,aq$
746. TENGERITE	$\ddot{C},\dot{Y},n\dot{H}$	

IV. Containing zinc, cobalt, nickel, copper.

747. ZARATITE	$\dot{Ni}\ddot{C}+2\dot{Ni}\dot{H}+3\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert Ni+2Ni\,H_2\Theta_2+3\,aq$
748. REMINGTONITE	$\dot{Co},\ddot{C},\dot{H}$	
749. HYDROZINCITE	$\dot{Zn}\ddot{C}+2\dot{Zn}\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert Zn+2Zn\,H_2\Theta_2$
750. AURICHALCITE	$\dot{Zn}\ddot{C}+\tfrac{3}{2}(\dot{Cu},\dot{Zn})\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert Zn+\tfrac{3}{2}(\Theta u,Zn)H_2\Theta_2$
751. MALACHITE	$\dot{Cu}\ddot{C}+\dot{Cu}\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert\Theta u+\Theta u\,H_2\Theta_2$
752. AZURITE	$\dot{Cu}\ddot{C}+\tfrac{1}{2}\dot{Cu}\dot{H}$	$\Theta\,\Theta\vert\Theta_2\vert\Theta u+\tfrac{1}{2}\Theta u\,H_2\Theta_2$

V. Containing bismuth or uranium.

753. BISMUTITE	$\ddot{Bi}\ \ddot{C}^{n},\dot{H}^{n}$
754. LIEBIGITE	$?\,\ddot{U}\ddot{C}+\dot{Ca}\ddot{C}+20\dot{H}$
755. VOGLITE	$\ddot{U},\dot{Ca},\dot{Cu}\ddot{C},\dot{H}$

735. TESCHEMACHERITE. Bicarbonate of Ammonia *E. F. Teschemacher*, Phil. Mag., xxviii. 548, 1846. Teschemacherite *Dana*.

In crystals having two brilliant cleavages meeting at 112°. G.=1·45. H.=1·5. Yellowish to white.

Comp.—$(\frac{1}{2}\,NH^4O+\frac{1}{2}\,HO)\,\ddot{C}$=Ammonia 32·9, carbonic acid 55·7, water 11·4=100. Analysis: Phipson (J. Ch. Soc., II. i. 74):

	$\ddot{C}$	NH_4O	$\dot{H}$	$\dot{C}a$
Chincha Islands	51·53	29·76	11·00	6·02, $\overset{\cdot\cdot\cdot}{\ddot{P}}$ 0·60, $\dot{M}g$, $\dddot{S}$, Cl *tr.*, alk. and uric acid 1·09=100 Phips.

The material analyzed by Phipson was white, compact, crystalline, and fragile, and had a strong odor of ammonia, from which he infers the presence either of free ammonia or of sesquicarbonate.

Pyr., etc.—In the closed tube for the most part volatilized, giving the odor of ammonia, a white sublimate of carbonate of ammonia, while an abundance of water condenses on the tube. Soluble in water, and heated with a fixed alkali gives a strong odor of ammonia. Effervesces with acids. Reacts alkaline to test paper.

Obs.—From guano deposits on the coast of Africa and Patagonia, and the Chincha Islands. Forms a bed several inches thick in the lowest parts of the guano deposits of Patagonia, as announced by Teschemacher; and similarly at the Chincha Islands, according to Phipson.

Bicarbonate of potash has been announced by Pisani (C. R., lx. 918, 1865) as found under a dead tree at Chypis in Valais, as a result of recent decomposition, and has been called by him Kalicine; he regarding it as a mineral as much as struvite. (Struvite has better claims, however, as it occurs in guano deposits, some of which date from the Post-tertiary at least.) He obtained for its composition Carbonic acid 42·20, potash 42·60, water 7·76, $\dot{C}a\,\ddot{C}$ 2·50, $\dot{M}g\,\ddot{C}$ 1·34, sand, etc. 3·60=100.

736. NATRON. Νιτρον, Nitrum, *of the Ancients*. Carbonate of Soda. Soude carbonatée.

Monoclinic: *C*=58° 52′, *I* ∧ *I*=76° 28′, *O* ∧ 1-ì=140° 9½′. Cleavage: *O* distinct; *i-ì* imperfect; *I* in traces.

H.=1—1·5. G.=1·423. Vitreous to earthy. White, sometimes gray or yellow, owing to impurities. Taste alkaline.

Comp.—$\dot{N}a\,\ddot{C}+10\,\dot{H}$=Carbonic acid 26·7, soda 18·8, water 54·5. Effervesces strongly with nitric acid.

Obs.—Occurs in nature only in solution, or mixed with the other carbonates of soda. See under *Trona* and *Thermonatrite*

737. THERMONATRITE. Νιτρον and Nitrum pt. *Vet.* Natron, Alkali orientale impurum terrestre, Jordblandadt Alkaliskt-salt, *Wall.*, Min., 174, 1747. Naturliches mineralisches Alkali *Wern.*; Thermonatrit *Haid.*, Handb., 487, 1845. Thermonitrit *Hausm.*, Handb., 1411, 1847. Soude carbonatée prismatique.

Orthorhombic. Observed planes: *I*, *i*-ĭ, *i*-ī, 1-ī, ½. *I* ∧ *i*-ī=138° 5′, *i*-ĭ ∧ *i*-ĭ, front,=58° 14′, lat.,=121° 46′, 1-ī ∧ 1-ī, top,=107° 50, *i*-ī ∧ 1-ī =126° 5′, *i*-ī ∧ ½=109° 6′, *I* ∧ ½=116° 5′, *I* ∧ *I*=96° 10′. In rectangular tables flattened parallel to *i*-ī, with sides bevelled by *I* and 1-ī. Usual as an efflorescence.

H.=1—1·5. G.=1·5—1·6. Lustre vitreous. White, grayish, yellowish.

Comp.—$\dot{N}a\,\ddot{C}+\dot{H}$=Carbonic acid 35·5, soda 50·0, water 14·5=100 Analyses: 1, 2, Beudant (Tr., ii. 310); 3, Pfeiffer (Ann. Ch. Pharm., lxxxix. 219):

	$\dot{Na}\ddot{C}$	$\dot{Na}\dddot{S}$	Na Cl, etc.	$\dot{H}$
1. Debreczin	73·6	10·4	2·2	13·8=100 Beudant.
2. Egypt	74·7	7·3	3·1	13·5, earthy matter 4·1=100 Beudant.
3. E. Indies	52·89	11·44	0·77	28·25, $\dot{K}\ddot{C}$ 6·65=100 Pfeiffer.

Obs.—Crystals may be obtained from a solution at a temperature between 25° and 37° C. It occurs in various lakes, and as an efflorescence over the soil in many dry regions of the globe; also about some mines and volcanoes.

There appears to be also an *anhydrous* carbonate of soda in nature. Kayser obtained for a specimen from the Neue Margarethe mine, near Clausthal, $\dot{Na}\ddot{C}$ 92·07, $\dot{Mg}\ddot{C}$ 3·32, $\dot{Ca}\ddot{C}$ 1·81, $\dot{Fe}\ddot{C}$ 0·19, $\dot{H}$ 1·85. And Wackenroder gives for the composition of a substance from Debreczin, Hungary, $\dot{Na}\ddot{C}$ 92·30, $\dot{Na}\dddot{S}$ 1·67, $\dot{K}\dddot{S}$ 0·03, $\dot{Na}\overset{.....}{P}$ 1·47, Na Cl 4·46=99·93; but it is said that the latter may be from an artificial product.

Crystals of the simple carbonate of soda (natron) become thermonatrite in efflorescing.

738. TRONA.

Trona *Bagge*, Ac. H. Stockh., xxxv. 1773. Natrum von Tripole, Stralige Natrum, *Klaproth*, Beitr., iii. 83, 1802. Sesquicarbonate of Soda. Urao *Boussingault*, Ann. d. M., xii. 278.

Monoclinic. $O \wedge i\text{-}i=103°\ 15'$. Cleavage: *i-i* perfect. Often fibrous or columnar massive.

H.=2·5—3. G.=2·11. Lustre vitreous, glistening. Color gray or yellowish-white. Translucent. Taste alkaline. Not altered by exposure to a dry atmosphere.

Comp.—$\dot{Na}^2\ddot{C}^3+4\dot{H}=(\frac{2}{3}\dot{Na}+\frac{1}{3}\dot{H})\ddot{C}+\dot{H}$=Carbonic acid 40·2, soda 37·8, water 22·0. Analysis by Klaproth of the African (Beitr., iii. 83): Carbonic acid 38, soda 37, water 22·5, sulphate of soda 2·5=100; by Boussingault of the *urao* (l. c.): $\ddot{C}$ 39·00, $\dot{Na}$ 41·22, $\dot{H}$ 18·80=99·02. The African is often mixed with the simple carbonate of soda, thermonatrite, and common salt. A specimen of trona from an extensive bed in Churchill County, Nevada, gave on analysis by C. S. Rodman (priv. contrib.), $\ddot{C}$ 38·70, $\dot{Na}$ 39·97, $\dot{H}$ 19·42, Na Cl 1·88, $\dot{Na}\dddot{S}$ 0·39, $\ddot{Si}$ 0·13=100·49.

Pyr., etc.—In the closed tube yields water and carbonic acid. B.B. imparts an intensely yellow color to the flame. Soluble in water, and effervesces with acids. Reacts alkaline with moistened test paper.

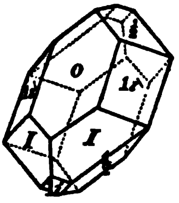
Obs.—The specimen analyzed by Klaproth came from the province of Suckenna, two days' journey from Fezzan, Africa. It is found at the foot of a mountain, forming a crust varying from the thickness of an inch to that of the back of a knife-blade. To this species belongs the urao found at the bottom of a lake in Maracaibo, S. A., a day's journey from Merida. Efflorescences of trona occur near the Sweetwater river, Rocky Mountains, mixed with sulphate of soda and common salt.

739. GAY-LUSSITE.

Boussingault, Ann. Ch. Phys., xxxi. 270, 1826.

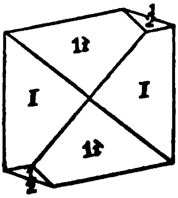
Monoclinic. $C=78°\ 27'$, $I \wedge I=68°\ 50'$ and $111°\ 10'$, $O \wedge 1\text{-}\grave{i}=125°\ 15'$; $a:b:c=0·96945:1:0·67137$. Observed planes: *O*; vertical, *I*, *i-ì*, *i-ì*; dome, 1-*i*, 1-*ì*; hemioctahedral, ½. Angles from Phillips.

606

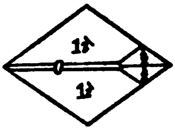


Maracaibo.

607



607A



Nevada.

$O \wedge 1\text{-}i=130°\ 21'$
$O \wedge i\text{-}i=101\ 33$
$O \wedge \frac{1}{2}=136\ 39$
$O \wedge I=96\ 30$
$I \wedge 1\text{-}\grave{i}=137\ 45$
$1\text{-}\grave{i} \wedge 1\text{-}\grave{i}$, ov. O, $=70\ 30$
$1\text{-}\grave{i} \wedge 1\text{-}\grave{i}$, adj., $=109\ 30$
$\frac{1}{2} \wedge \frac{1}{2}=110\ 30$
$I \wedge i\text{-}i=124\ 25$

Crystals often lengthened, and prismatic in the direction of 1-ì; also in that of ½; also (fr. Nevada) not elongate, but thin in the direction of the orthodiagonal, *O* being very narrow or wanting; surfaces usually uneven, being formed of minute subordinate planes. Cleavage: *I* perfect; *O* less so, but giving a reflected image in a strong light.

H.=2—3. G.=1·92—1·99. Lustre vitreous. Color white, yellowish-white. Streak uncolored to grayish. Translucent. Fracture conchoidal. Extremely brittle. Not phosphorescent by friction or heat.

Comp.—$\dot{Na}\ddot{C}+\dot{Ca}\ddot{C}+5\dot{H}=(\frac{1}{2}\dot{Na}+\frac{1}{2}\dot{Ca})\ddot{C}+2\frac{1}{2}\dot{H}$=Carbonate of soda 35·9, carbonate of lime 33·8, water 30·3=100. Analysis by J. B. Boussingault (Ann. Ch. Phys., III. vii. 488, 1848):

$\dot{Na}\ddot{C}$ 34·5 $\dot{Ca}\ddot{C}$ 33·6 $\dot{H}$ 30·4 Clay 1·5=100.

Pyr., etc.—Heated in a matrass the crystals decrepitate and become opaque. B.B. fuses easily to a white enamel, and colors the flame intensely yellow. With the fluxes it behaves like carbonate of lime. Dissolves in acids with a brisk effervescence; partly soluble in water, and reddens turmeric.

Obs.—Abundant at Lagunilla, near Merida, in Maracaibo, where its crystals are disseminated at the bottom of a small lake, in a bed of clay, covering *urao;* the natives call it *clavos* or *nails*, in allusion to its crystalline form.

Also abundant on a small island in Little Salt Lake, near Ragtown, Nevada, about 1½ m. S. of the main emigrant road to Humboldt. The lake is in a crater-shaped basin, and its waters are dense and strongly saline.

The Nevada crystals gave J. M. Blake (Am. J. Sci., II. xlii. 221), from whom f. 607, 607A, are taken, the following approximate angles, the planes, owing to the unevenness, not affording results nearer than a degree: *I* ∧ *I*=110° 35′ to 112° 30′, 69° 5′; 1-*ì* ∧ 1-*ì*=110° 30′, 110° 10′; *O* ∧ 1-*ì*=126° 10′, 125° 30′; *O* ∧ *i-i*=79°; *O* ∧ *I*=96° 10′; *I* ∧ ½=127° 10′, 127° 55′.

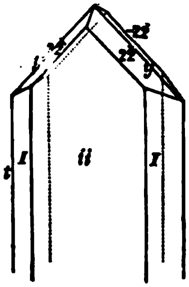
Named after Gay Lussac.

Artif.—J. Fritzsche has produced artificial gay-lussite by mixing eight parts by volume of a saturated solution of carbonate of soda with one of a solution of chlorid of calcium of 1·130—1·150 specific gravity (J. pr. Ch., xciii. 339).

740. HYDROMAGNESITE.

T. Wachtmeister, Ak. H. Stockh., 1827, 18. Hydromagnesit *v. Kobell*, J. pr. Ch., iv. 80, 1835. Hydrocarbonate of Magnesia. Lancasterite pt. *Silliman, Jr.*, Am. J. Sci., II. ix. 226, 1850. Magnesia alba *Pharm.*

608



Monoclinic. *C*=82°—83°, *I* ∧ *I*=87° 52′ to 88°, *O* ∧ 2-*ì*=137°; *a* : *b* : *c*=(nearly) 0·455 : 1 : 1·0973. Observed planes as in the annexed figure. 2-*ì* ∧ -2-*ì*, adj.,=143½° to 145°, *i-i* ∧ 2-*ì*=113½° to 112°, *i-i* ∧ -2-*ì* =105°. Culminant angle between edges *y*, *y* (or 2-*ì* ∧ 2-*ì*)=94°, edge *t* on edge *y* (or *i-ì* ∧ 2-*ì*)=133°. Crystals small, usually acicular or bladed, and tufted. Also amorphous; as chalky or mealy crusts.

H. of crystals 3·5. G.=2·145—2·18, Smith & Brush. Lustre vitreous to silky or subpearly; also earthy. Color and streak white. Brittle.

Comp.—$3(\dot{Mg}\ddot{C}+\dot{H})+\dot{Mg}\dot{H}$=Magnesia 43·9, carbonic acid 36·3, water 19·8=100. Analyses 1, Wachtmeister (l. c.); 2, v. Kobell (J. pr Ch., iv. 80); 3, 4, Smith & Brush, of crystalline varieties (Am. J. Sci., II. xv. 214):

	$\ddot{C}$	$\dot{Mg}$	$\dot{H}$	$\ddot{Si}$
1. Hoboken	36·82	42·41	18·53	0·57, $\ddot{Fe}$ 0·27, earthy matter 1·89=99·99 W
2. Negroponte	36·00	43·96	19·68	0·36=100 Kobell.
3. Texas, Pa., Wood's Mine	36·69	43·20	19·43	——, Fe and Mn *tr.*=99·72 Smith & Brush.
4. " Low's Mine	36·74	42·80	20·10	——, Fe and Mn *tr.*=99·14 Smith & Brush.

Pyr., etc.—In the closed tube gives off water and carbonic acid. B.B. infusible, but whitens and the assay reacts alkaline to turmeric paper. Soluble in acids; the crystalline compact varieties are but slowly acted upon by cold acid, but dissolve with effervescence in hot acid.

Obs.—Occurs at Hrubschitz, in Moravia, in serpentine; in Negroponte, near Kumi; at Kaiserstuhl, in Baden, impure. In the U. States, crystallized, with serpentine and brucite, near Texas, Lancaster Co., Penn., at Wood's and Low's mines; also in a similar way at Hoboken, N. J., in acicular crystals like natrolite: at the latter place in earthy crusts. The brucite of Hoboken sometimes changes on exposure to an earthy hydromagnesite.

The above angles and figure were taken by the author from a Hoboken crystal $\frac{1}{16}$ in. broad, in which the summit planes were smooth and brilliant, the prismatic striated. The rhombic prism in one crystal gave the angles 95° 20′ and 84° 50′; but other crystals gave different results, and no constant value was obtained. The species is isomorphous with wollastonite (p. 156).

The *Lancasterite* of Silliman (l. c.) is shown by Smith and Brush to be a mixture of brucite and hydromagnesite.

Found pseudomorphous of brucite at Wood's mine.

741. HYDRODOLOMITE. Hydromagnesit *v. Kobell*, J. pr. Ch., xxxvi. 304, 1845. Kalkmagnesit *Hausm.*, Handb., 1404, 1847. Hydromanganocalcit *Hartmann*, Nachr., 299. Hydromagnocalcit pt. Hydrodolomit *Ramm.* Hydronickelmagnesite *Shep.*, Am. J. Sci., II. vi. 250, 1848. Pennite *Herm.*, J. pr. Ch., xlvii. 13, 1849.

Massive. In stalactitic and stalagmitic forms, and globular concretions and crusts.

G.=2·495, Ramm. Color yellowish-white, grayish, greenish.

Var.—(1) Hydrodolomite of Vesuvius is stalactitic or sinter-like; G.=2·495. (2) *Pennite* of Hermann, from Texas, Pa., is in apple-green to whitish crusts, having a surface of minute spherules; the color is due to nickel; G.=2·86.

Comp.—$(\dot{C}a, \dot{M}g)\ddot{C}+\frac{1}{3}\dot{H}$, Ramm., from his anal. of specimen received from Scacchi, of Naples; Hermann's analysis affords $(\frac{1}{3}\dot{C}a+\frac{2}{3}\dot{M}g)\ddot{C}+\frac{1}{3}\dot{H}$; von Kobell's, $\dot{R}^4\ddot{C}^3 4\dot{H}$. Analyses: 1, v. Kobell (l. c.); 2, Rammelsberg (Min. Ch., 234); 3, Hermann (l. c.):

	$\ddot{C}$	$\dot{C}a$	$\dot{M}g$	$\dot{N}i$	$\dot{F}e$	$\dot{M}n$	$\dot{H}$
1. Vesuvius	33·10	25·22	24·28	—	—	—	17·40 Kobell.
2. "	43·40	26·90	23·23	—	—	—	6·47 Rammelsberg.
3. *Pennite*	44·54	20·10	27·02	1·25	0·70	0·40	5·84, $\bar{A}l$ 0·15=100 Hermann.

Pyr., etc.—Like dolomite, but yields water in the closed tube.

Obs.—The Vesuvian mineral is found on Mt. Somma. Pennite occurs on serpentine and chromic iron, with zaratite, at Texas, Pa., and seems to graduate into zaratite; also at Swinaness and Haroldswick, in Unst, Shetlands.

742. PREDAZZITE. *Petzholdt* pt., Beitr. Geogn. Tyrol, 194, 1843.

Massive, granular, as a fine-grained dolomite-like rock.

H.=3·5. G.=2·634. Lustre vitreous. White to grayish-white.

Comp.—$2\dot{C}a\ddot{C}+\dot{M}g\dot{H}$=Carbonic acid 34·1, lime 43·4, magnesia 15·5, water 7·0=100. Analyses by Roth (J. pr. Ch., lii. 346):

	$\ddot{C}$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$
1. Predazzo	33·51	14·61	44·89	6·99=100.
2. "	34·25	14·16	42·97	7·06=98·44.

In the analyses some $\dddot{S}i$ and $\bar{A}l$ were obtained.

Pyr., etc.—Like hydrodolomite.

Obs.—From Canzacoli, near Predazzo, in the southern Tyrol, where it occurs as a marble-like rock. The rock in some places contains brucite. May it be a mixture?

743. PENCATITE. *Roth*, ZS. G. Ges., iii. 140, 143.

Similar to the predazzite, and from the same region; G.=2·613, Roth

2·57, Damour. Also as a bluish-gray limestone, somewhat yellowish, from Vesuvius; H.=3; G.=2·524, Roth; 2·534, in powder.

Comp.—$\dot{C}a\,\ddot{C}+\dot{M}g\,\dot{H}$=Carbonic acid 27·9, lime 35·4, magnesia 25·3, water 11·4=100. Analyses: 1, 2, Damour (Bull. Soc. G. Fr., II. iv. 1052, 1847); 3–5, Roth (J. pr. Ch., lii. 350, ZS. G., iii. 140):

	$\ddot{C}$	$\dot{M}g$	$\dot{C}a$	$\dot{H}$
1. Predazzo	25·00	24·32	35·42	10·89, $\ddot{\overline{F}}e$ 0·45, $\ddot{S}i$ 0·60=96·68 Damour.
2. "	26·40	24·64	35·47	10·50, " 0·50, " 0·55=98·06 Damour.
3. "	29·23	24·78	35·70	10·92=100·63 Roth.
4. "	28·10	24·47	35·97	10·97=97·51 Roth.
5. Vesuvius	29·66	23·68	35·45	[10·59], $\ddot{\overline{A}}l$, $\ddot{\overline{F}}e$ 0·62=100 Roth.

In two determinations Roth obtained for the last 11·75 $\dot{H}$, 10·78 $\dot{H}$. The Vesuvian mineral is the same that Klaproth analyzed (Beitr., v. 91) without finding the magnesia. Roth observes that, as the water is retained even to 360° and 400° C., the mineral must be regarded as a chemical compound. Damour observed pure hydromagnesite in clefts in the Predazzo rock.

Named after Marzari Pencati, of the Tyrol.

744. HOVITE. Hovite, Native Carbonate of Alumina and Lime, *J. H. & G. Gladstone*, Phil. Mag., IV. xxiii. 462, 1862.

Soft, white, and friable; earthy in fracture.

Comp.—$(\frac{1}{2}\dot{C}a+\frac{1}{2}\dot{H})\ddot{C}+aq$=Carbonic acid 44·4, carbonate of lime 28·3, water 27·3=100. The compound ordinarily called bicarbonate of lime.

The mineral is known only as a mixture in *collyrite*, a hydrous silicate of alumina.

J. H. & G. Gladstone state (l. c.) that there is carbonic acid enough in the collyrite to form a *bicarbonate* with the lime present; but this view of the composition is set aside because of the solubility of the so-called bicarbonate, and its being unknown in the solid state; and hence they suggest that the excess of carbonic acid may be combined in the mineral with alumina, making a *hydrous carbonate of alumina and lime*, or perhaps replaces part of the silica in the alumina-silicate.

But although the bicarbonate referred to is known only in solution, the most likely condition for finding it in the mineral kingdom is in one of the hydrous silicates of alumina, like collyrite, in which there is present much water, loosely held; the mineral, therefore, is most probably a carbonate of the formula above given; especially since a carbonate in which $\ddot{\overline{A}}l$ or $\ddot{\overline{F}}e$ enters is, as the authors admit, yet unknown to chemistry.

Analyses of the collyrite containing the carbonate, by J. H. & G. Gladstone (l. c.):

	$\ddot{S}i$	$\ddot{C}$	$\ddot{\overline{A}}l$	$\dot{C}a$	$\dot{H}$
1.	6·22	10·91	41·04	7·37	33·16=98·70.
2.	5·87	14·77	39·58	11·22	[28·56]
3.	5·41	18·15	36·32	11·62	[29·16]
4.	5·30	14·14	40·51	9·18	[30·87]

The excess of $\ddot{C}$ over that neutralizing the lime is in 1, 5·12 p. c.; in 2, 5·96; 3, 9·02; 4, 6·94 p. c.

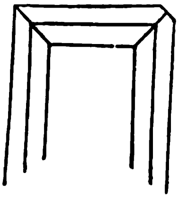
Obs.—From Hove, near Brighton, in an old quarry in the upper chalk, in fissures that cut through layers of flint, along with collyrite.

745. LANTHANITE. Kohlensaures Cereroxydul *Berz.*, ZS. f. Min., ii. 209, 1825; Kohl. Ceroxydul *Hisinger*, Afh. Min. Geog. Schwed., 144, 1826. Carbonate of Cerium. Carbocérine *Beud.*, Tr., ii. 354, 1832. Lanthanit *Haid.*, Handb., 500, 1845. Hydrolanthanit *Glocker*, Synops. 248, 1847.

Orthorhombic. $I \wedge I$=93° 30′—94°, Blake, 92° 46′, v. Lang; $I \wedge 1$=142° 36′; $a:b:c$ = 0·99898 : 1 : 1·0496, v. Lang. In thin four-sided plates or minute tables, with bevelled edges, as in the annexed figures. Cleavage micaceous. Also fine granular or earthy.

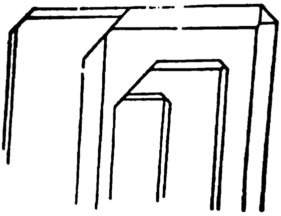
H. =2·5—3. G.=2·666, (?) Blake; 2·605, Genth. Lustre pearly or dull. Color grayish-white, delicate pink, or yellowish.

609



Saucon Valley, Pa.

610



Saucon Valley, Pa.

Comp.—$\dot{La}\ddot{C}+3\dot{H}$=Lanthana 52·6, carbonic acid 21·3, water 26·1=100. Analyses: 1, 2, J. L. Smith (Am. J. Sci., II. xvi. 230, xviii. 378); 3, F. A. Genth (ib., xxiii. 425):

		$\ddot{C}$	$\dot{La}$	$\dot{H}$	
1.	Saucon valley	22·58	54·90	24·09	Smith.
2.	" "	21·95	55·03	24 21	Smith.
3.	" "	21·08	54·95	[23·97]	Genth.

There is some oxyd of didymium with the lanthana, according to Smith.

Blake obtained $\dot{La}$ 54·27, 54·93, 54·64, $\ddot{C}$ 19·13, $\ddot{C}+\dot{H}$ (by ign.) 45·07, 45·36.

Hisinger found in a Swedish specimen, probably impure, $\dot{La}$ 75·7, $\ddot{C}$ 10·8, $\dot{H}$ 13·5, whence the formula $\dot{La}^3\ddot{C}+3\dot{H}$.

Pyr., etc.—In the closed tube yields water. B.B. infusible; but whitens and becomes opaque, silvery, and brownish; with borax, a glass, slightly bluish, reddish, or amethystine, on cooling; with salt of phosphorus a glass, bluish amethystine while hot, red cold, the bead becoming opaque when but slightly heated, and retaining a pink color. Effervesces in the acids.

Obs.—Found coating cerite at Bastnäs, Sweden; also in Silurian limestone with the zinc ores of the Saucon valley, Lehigh Co., Pa., in masses consisting of aggregated minute tables; at the Sandford iron-ore bed, Moriah, Essex Co., N. Y., in delicate scales, and a thin scaly crust, in fissures in the ore, and on crystals of allanite. Reported by Shepard as occurring at the Canton mine, Ga., in pink-colored crystals, lining cavities of botryoidal white pyrite.

On cryst., W. P. Blake, Am. J. Sci., II. xvi. 228, 1853, and this Min., 1854, with the above figs.; v. Lang, Phil. Mag., IV. xxv. 43, 1863; both on Pennsylvania crystals.

746. TENGERITE. Kolsyrad Ytterjord *A. F. Svanberg* and *C. Tenger*, Arsb., xviii. 206, 1838. Ytterspath *Germ.* Tengerite *Dana.*

Pulverulent. In thin coatings. Sometimes an appearance of radiated crystallization.

Lustre dull, or like that of chalk. Color white.

Comp.—A carbonate of yttria, according to Svanberg and Tenger, but no analysis has been published.

Pyr., etc.—In the closed tube yields a considerable amount of water (Brush). Effervesces with acids.

Obs.—Occurs as a thin coating on gadolinite at Ytterby, and is evidently a result of its alteration.

747. ZARATITE. Hydrate of Nickel (fr. Texas, Pa.) *Silliman, Jr.*, Am. J. Sci., II. iii. 407, 1847; Emerald Nickel *id.*, ib., vi. 248, 1848. Nickel Smaragd *Germ.*; Texasit *Kenng.*, Min., 1853. Carbonato hidratado de Niquel (fr. Spain) *A. Casares*, A. M. Alcibar in Min. Revista of Madrid, 304, 1850; Zaratita *Casares*, ib., 176, March, 1851. Zaratit *wrong orthogr.*

Incrusting; often small stalactitic or minute mammillary; sometimes appearing prismatic with rounded summits. Also massive, compact.

H.=3—3·25. G.=2·57—2·693. Lustre vitreous. Color emerald-green. Streak paler. Transparent—translucent. Brittle.

Comp.—$\dot{\mathrm{Ni}}\ddot{\mathrm{C}}+2\dot{\mathrm{Ni}}\dot{\mathrm{H}}+4\dot{\mathrm{H}}$=Carbonic acid 11·7, oxyd of nickel 59·4, water 28·9=100. Magnesia seems to replace at times part of the oxyd of nickel, and, correspondingly, the color becomes paler; the mineral at Texas thus graduates toward pennite, which has the same concretionary aspect as much of the zaratite.

Analyses: 1, B. Silliman, Jr. (l. c.); 2, Smith and Brush (ib., xvi. 52):

	$\ddot{\mathrm{C}}$	$\dot{\mathrm{Ni}}$	$\dot{\mathrm{H}}$
1. Texas, Pa.	11·69	58·81	29·50=100 Silliman.
2. "	11·63	56·82	29·87, $\dot{\mathrm{Mg}}$ 1·68=100 S & B.

Pyr., etc.—In the closed tube yields water and carbonic acid, and leaves a grayish-black magnetic residue. B.B. infusible. With borax in O.F. gives a bead violet while hot and reddish-brown on cooling; in R.F. the bead becomes gray and opaque from reduced nickel. Dissolves easily with effervescence in heated dilute muriatic acid.

Obs.—Occurs on chromic iron at Texas, Lancaster Co., Pa., associated with serpentine; also at Swinaness in Unst, Shetland.

Also in Spain, near Cape Hortegal in Galicia, where it occurs as an incrustation on a magnetite in which there is some sulphid of nickel; it is in clear emerald-green, vitreous crusts, sometimes transparent, and also in stalactites. It proved to be a hydrated carbonate of nickel with a little carbonate of magnesia.

Named after Sen. Zarate of Spain. Casares's name antedates that of Kenngott.

748. REMINGTONITE. *J. C. Booth*, Am. J. Sci., II. xiv. 48, 1852.

A rose-colored incrustation, softy and earthy; opaque. Streak pale rose-colored.

Comp.—A hydrous carbonate of cobalt, but precise composition not ascertained. Dissolves in muriatic acid with a slight effervescence, making a green solution, the color due to iron. Cobalt reaction with borax.

Obs.—Occurs as a coating on thin veins of serpentine, which traverse hornblende and epidote, at a copper mine near Finksburg, Carroll Co., Maryland.

749. HYDROZINCITE. Calamine *Smithson*, Phil. Trans., 12, 1803. Zinkblüthe *Karst.*, Tabell., 70, 99, 1808. Hydro-carbonate of Zinc. Earthy Calamine. Zinconise *Beud.*, Tr., ii. 357, 1832. Zinc-Bloom. Hydrozinkit *Kenng.*, Min., 1853. Marionite *Elderhorst*, G. Rep. Arkansas, 153, 1858.

Massive, earthy or compact. As incrustations, the crusts sometimes concentric and agate-like. At times reniform, pisolitic, stalactitic.

H.=2—2·5. G.=3·58—3·8. Lustre dull. Color pure white, grayish or yellowish. Streak shining. Usually earthy or chalk-like.

Comp.—In part $\mathrm{Zn}\ddot{\mathrm{C}}+2\mathrm{Zn}\dot{\mathrm{H}}$=Carbonic acid 13·6, oxyd of zinc 75·3, water 11·1=100 Smithson's analysis gives 1 $\dot{\mathrm{H}}$ additional. For anal. 9, 10, 11, the O. ratio for $\dot{\mathrm{Zn}}$, $\ddot{\mathrm{C}}$, $\dot{\mathrm{H}}$=13 : 5 : 9; whence $5\dot{\mathrm{Zn}}\ddot{\mathrm{C}}+8\dot{\mathrm{Zn}}\dot{\mathrm{H}}+\dot{\mathrm{H}}$, Goebel=Carbonic acid 15·3, oxyd of zinc 73·4, water 11·3=100 The analyses of Sullivan (Nos. 11, 12, 13) give the formula $3\dot{\mathrm{Zn}}\ddot{\mathrm{C}}+5\dot{\mathrm{Zn}}\dot{\mathrm{H}}$=Carbonic acid 15·2 oxyd of zinc 74·5, water 10·3=100, which agrees very well with several of the other analyses

Analyses: 1, Smithson (l. c., the specimen a white chalky incrustation); 2, 3, Karsten (Syst. d Met., iv. 429); 4, Reichert (Ramm. Min. Ch., 239); 5, Schnabel (Pogg., cv. 144); 6–8, Braun Petersen, and Voit (Ann. Ch. Pharm., cviii. 48); 9, Koch (Ramm. Min. Ch., 239); 10, Terreil (C R., xlix. 558); 11–13, Sullivan (Dublin Q. J. Sci., ii. 135); 14, Bonnet (B. H. Ztg., xxii. 164); 15 A. Goebel (Bull. Ac. St. Pet., v. 407); 16, Elderhorst (l. c.):

	$\ddot{\mathrm{C}}$	$\dot{\mathrm{Zn}}$	$\dot{\mathrm{H}}$

13.	"	15·13	74·34	10·53=100 Sullivan.
14.	Guipuzcoa	15·01	73·88	11·11=100 Bonnet.
15.	Taft, Persia	(‡) 15·17	73·35	11·13=99·65 Goebel.
16.	Arkansas	15·01	73·26	11·81=100·08 Elderhorst.

The compact mineral loses 2·04 p. c. of water and carbonic acid on heating to 130° C., and 14·42 p. c. more on heating for 6 h. to 150° to 180° C. (Sullivan).

Schönichen describes (B. H. Ztg., xxii. 164) a snow-white, massive, subtranslucent material from near La Nestosa in Guipuzcoa, Spain, which contained $\ddot{S}i$ 31·50, $\ddot{\bar{A}}l$ 26·43—20·27, $\dot{Z}n$ 21·36—28·45, $\dot{H}$ 18·32—19·65. It is probably a mixture of hydrozincite and kaolinite.

Pyr., etc.—In the closed tube yields water; in other respects resembles smithsonite.

Obs.—Occurs at most mines of zinc, and is a result of the alteration of the other ores of this metal.

Found in great quantities at the Dolores mine, Udias valley, province of Santander, in Spain, along with calamine, smithsonite, and blende, covering the floor of an extensive cavern to a depth of a yard and a half, and hanging in dazzling white branching stalactites from the roof; part is concretionary, pisolitic, nodular; it is intimately mixed with silicate of zinc, and is pseudomorphous after it; and opal-like masses of silicate and hydrous carbonate are common, formed by the falling of drops of water holding the silicate in solution.

Also occurs in the neighboring province of Guipuzcoa, Spain, near La Nestosa, at the mines of Las Nieves and La Augustina; at Bleiberg and Raibel in Carinthia; near Reimsbeck, in Westphalia; in Hollenthal, on the Zugspitze in Bavaria; at Taft in the province of Jesd in Persia.

In the U States, at Friedensville, Pa.; at Linden, in Wisconsin, as a concretionary fibrous white crust on smithsonite; in Marion Co., Arkansas (*marionite*), in concentric and contorted laminæ and botryoidal crusts.

Beudant's name *zinconise*, from zinc and κόνις, powder, has priority, but is too badly formed to be retained.

Artif.—Deposited when hot solutions of zinc salts in water are decomposed by carbonates of the alkalies. The white substance formed on zinc, when moistened and exposed to the air, is a related compound, containing, according to Bonsdorff, $\ddot{C}$ 14·19, $\dot{Z}n$ 71·25, $\dot{H}$ 14·56=100, agreeing with Smithson's analysis above.

750. AURICHALCITE. Calamine verdâtre (containing "une bonne quantité de cuivre"), Mine de Laiton [=Brass-ore], *Patrin*, Aperçu d. Mines en Sibérie, in J. de Phys., xxxiii. 81, 1788. Mine de Laiton de Pise en Toscane, Aurichalcum of the ancients?, *Sage*, J. de Phys., xxxviii. 155, 1791. Messingblüthe *Germ.* Aurichalcit *Böttger*, Pogg., xlviii. 495, 1839. Buratite *Delesse*, Ann. Ch. Phys., III. xviii. 478, 1846. Orichalcit *Glocker*, Syn., 230, 1847.

In acicular crystals forming drusy incrustations; also columnar, divergent; plumose; granular; also laminated.

H.=2. Lustre pearly. Color pale green, verdigris-green; sometimes sky-blue. Streak pale greenish or bluish. Translucent.

Comp., Var.—A cuprous hydrozincite. For the original aurichalcite, O. ratio for $\dot{C}u$, $\dot{Z}n$, $\ddot{C}$, $\dot{H}$=2 : 3 : 4 : 3. 2 $\dot{C}u$ $\ddot{C}$+3 $\dot{Z}n$ $\dot{H}$, Böttger; or 2 $\dot{Z}n$ $\ddot{C}$ + 3 ($\dot{C}u$, $\dot{Z}n$) $\dot{H}$=Carbonic acid 16·2, oxyd of copper 29·2, oxyd of zinc 44·7, water 9·9=100.

For *buratite*, or the so-called lime-aurichalcite, according to Delesse, $\dot{R}$ $\ddot{C}$+$\dot{R}$ $\dot{H}$, in which $\dot{R}$=$\dot{C}u$, $\dot{Z}n$, $\dot{C}a$, in the ratio 10 : 14 : 1 in the Chessy mineral, and 7 : 8 : 3 in the Altai. But the lime is probably from mixed calcite, as suggested by Berzelius; and, this removed, the formula is that above given, as shown by Risse.

A Santander variety, analyzed by Risse, containing much less copper (anal. 6, 7), affords th formula $(\dot{Cu}, \dot{Zn})\ddot{C}+2\dot{Zn}\dot{H}$, with $\dot{Cu}$ to $\dot{Zn}$ in the first member as 3 : 1, the O. ratio for $\dot{Cu}$, $\dot{Zn}$, $\ddot{C}$, $\dot{H}$ being 3 : 9 : 8 : 8.

Analyses: 1, 2, Böttger (l. c.); 3, Connel (Ed. N. Phil. J., xlv. 36); 4, 5, Delesse (l. c.); 6. 7 H. Risse (Verh. nat. Ver. Bonn, 95, 1865):

	$\ddot{C}$	$\dot{H}$	$\dot{Cu}$	$\dot{Zn}$	$\dot{Ca}$
1. Altai, *Aurichalc.*	16·06	9·95	28·19	45·84	——=100·06 Böttger.
2. " "	16·08	9·93	28·36	45·62	——=99·99 Böttger.
3. Matlock, "	27·5		32·5	42·5	*tr.*=102·5 Connel.
4. Altai, *Buratite*	21·45	——	29·46	32·02	8·62=100 Delesse.
5. Chessy, "	19·88	——	29·00	41·19	2·16=99·85 Delesse.
6. Santander	14·08	10 80	18·41	55·29	—, gangue 1·86=100·44 Risse.
7. "	24 69		16·03	56·82	—, gangue 1·69=99·23 Risse.

Pyr., etc.—In the closed tube blackens, and yields water. B.B. infusible; colors the flame deep green. With soda on charcoal gives a coating of oxyd of zinc, yellow while hot and white on cooling; moistened with cobalt solution and heated in O.F. the coating becomes green; the fused mass removed from the coal and triturated in a mortar affords minute globules of copper. With the fluxes reacts for copper. Soluble in acids with effervescence.

Obs.—Aurichalcite occurs at Loktefskoi, at a copper mine of the Altai, where it is associated with calcite and limonite, sometimes forming a drusy covering upon these minerals; at Matlock, in Derbyshire, of a pale green color, laminated structure, and pearly lustre; at Roughten-Gill, in Cumberland; Leadhills, Scotland; zinc mines of the province of Santander, Spain. In the U. States, at Lancaster, Pa. (Taylor, Am. J. Sci., II. xx. 412).

The buratite comes from Loktefskoi; Chessy, near Lyons; Framont, Tyrol; Retzbanya, in Hungary, in microscopic rhombic or rhombohedral tables, and also oblong rectangular forms (a mineral lately proved to be calciferous); Campiglia in Tuscany.

The mineral aurichalcite was first described as a greenish variety of calamine by Patrin, in 1788 (l. c.), and called *Brass ore* (Mine de Laiton), "because," as he says, "the compound of copper and zinc is here made by nature." Among the brass or copper ores of the ancients, *aurichalcum* was reputed the best (Pliny, xxxiii. 2); and Sage was thence led to suggest (l. c. 1791) that the *cupriferous calamine*.(which afforded, as he showed by experiment, the best of brass, without the addition of either copper or zinc) might be the ancient *aurichalcum*. As the ore is a scarce one, this is not at all probable. But the idea explains the use of the word for the species. In addition, it is to be said that brass (or an alloy related to it) was called *aurichalcum* by Virgil and Horace, and also in the middle ages.

The Latin word *aurichalcum* is regarded by some good authorities as derived from ὀρείχαλκος (=*mountain brass*); and, in fact, the Latin poets just mentioned wrote it *orichalcum*. But others regard it as a hybrid word (from the Latin *aurum*, *gold*, and χαλκός, *brass* or *bronze*), and the *o* of the poets as an example of the admissible change in Latin of *au* to *o*. Glocker, in view of the first of these derivations, changes aurichalcite to *orichalcite*; but, whatever the derivation, as the use of *aurichalcum* dates from before Pliny's time, we moderns may as well let it stand without correction.

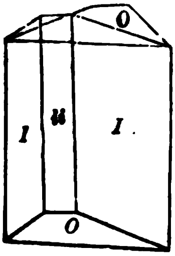
750A. Zinkazurite *Breith.*, B. H. Ztg., 1852, 101. A blue mineral in small crystals, having G.=3·49, from the Sierra Almagrera in Spain. Heated, it affords a little water, with the reactions of copper and zinc. According to Plattner, it consists of sulphate of zinc, carbonate of copper, and some water.

751. MALACHITE. Χρυσοκόλλα pt. *Theophr.*, *Dioscor.*, etc. Ψευδὴς Σμάραγδος [False Emerald of Copper Mines] pt., *Theophr.* Chrysocolla, Molochites, pt., *Plin.*, *Agric.* Berggrün, *Germ.* Molochit, *Agric.*, Interpr., 1546. Cuivre carbonaté vert *L'Abbé Fontana*, J. de Phys., ii. 509, 1778, proving the existence of a green carbonate. Green Carbonate of Copper; Green Malachite; Mountain Green pt. Berggrün pt. *Germ.* Atlaserz [fib. var.] *Germ.*

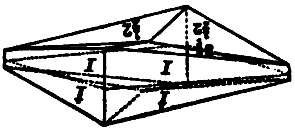
Monoclinic. $C=88°\ 32'$; $I \wedge I=104°\ 28'$, $i\text{-}i \wedge -1\text{-}i=118°\ 15'$, Zepharovich; $a:b:c=0·51155:1:1·2903$. Observed planes: O; vertical, I, $i\text{-}i$, $i\text{-}\grave{i}$; hemidomes, $-1\text{-}i$, $-\frac{1}{4}\text{-}i$, $\frac{1}{2}\text{-}i$, $\frac{1}{3}\text{-}i$, $\frac{1}{4}\text{-}i$; hemioctahedral, $\frac{1}{2}$, $\frac{1}{3}\text{-}2$, $\frac{3}{4}\text{-}3$. $O \wedge i\text{-}i=91°\ 28'$, $I \wedge i\text{-}i=142°\ 14'$; $I \wedge \frac{1}{2}=107°$, $\frac{1}{2} \wedge \frac{1}{3}\text{-}i=168°$, $\frac{1}{3}\text{-}2 \wedge \frac{1}{3}\text{-}2=157°\ 30'$—$156°\ 38'$ (obs. by Lang.), $-1\text{-}i \wedge -1\text{-}i$, reëntering angle in twin, f. 611,=123°

22′, Zeph. obs.; $\frac{1}{2}$-*i* ∧ $\frac{1}{2}$-*i*, reënt. in twin, 163° 20′—36′, Lang obs. Common form, f. 611; also same with other terminal planes; also with *i*-*i* wanting; also with *i*-*i*, *i*-*ì* very large, making a rectangular prism; also with the vertical prism very short, as in f. 612. Crystals rarely simple. Twins: composition-face *i*-*i*, f. 611; the reëntering angle varying with the terminating planes; often penetration twins, as in f. 612, in which the upper and lower halves in front are continued respectively in the lower and upper halves behind, as illustrated in f. 612A, a clinodiagonal vertical section of 612; also under the terminal planes of 611 in 613. Cleavage: basal, highly perfect; clinodiagonal less distinct. Usually massive or incrusting, with surface tuberose, botryoidal, or stalactitic, and structure divergent; often delicately compact fibrous, and banded in color; frequently granular or earthy.

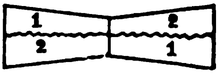
611



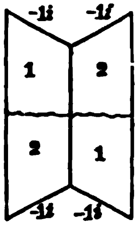
612



612A



613



H.=3·5—4. G.=3·7—4·01. Lustre of crystals adamantine, inclining to vitreous; of fibrous varieties more or less silky; often dull and earthy. Color bright green. Streak paler green. Translucent—subtranslucent—opaque. Fracture subconchoidal, uneven.

Comp.—$\dot{C}u^2\ddot{C}+\dot{H}=\dot{C}u\ddot{C}+\dot{C}u\dot{H}$=Carbonic acid 19·9, protoxyd of copper 71·9, water 8·2=100. Analyses: 1, Klaproth (Beitr., ii. 287, 1797); 2, Vauquelin (Ann. du Mus., xx. 1); 3, Phillips (J Royal Inst., iv. 276); 4, J. L. Smith (Am. J. Sci., II. xx. 249):

	$\ddot{C}$	$\dot{C}u$	$\dot{H}$
1. Turjinsk, Ural	18·0	70·5	11·5=100 Klaproth.
2. Chessy	21·25	70·10	8·75=100·10 Vauquelin.
3. "	18·5	72·2	9·3=100 Phillips.
4. Phenixville	19·09	71·46	9·02, $\dot{F}e$ 0·12=99·69 Smith.

Fontana, the first analyst of the species, obtained (l. c.) $\ddot{C}$ 19·4, $\dot{H}$ 5·6, leaving 75 p. c. for the copper. Other analyses: ores from the Urals and Finland, by A. E Nordenskiöld (Act. Soc. Sci. Fenn., iv. 607); Ural, by Struve (Verh. Ges. St. Petersb., 1850–51, 103).

Pyr., etc.—In the closed tube blackens and yields water. B.B. fuses at 2, coloring the flame emerald-green; on charcoal is reduced to metallic copper; with the fluxes reacts like melaconite. Soluble in acids with effervescence.

Obs.—Green malachite accompanies other ores of copper. Perfect crystals are quite rare Occurs abundantly in the Urals; at Chessy in France, in the old mine at Sandlodge, in Shetland at Schwatz in the Tyrol; in Cornwall and in Cumberland, England; Sandlodge copper mine, Scotland; Limerick, Waterford, and elsewhere, Ireland; at Grimberg, near Siegen, in Germany. At the copper mines of Nischne Tagilsk, belonging to M. Demidoff, a bed of malachite was opened which yielded many tons of malachite; one mass measured at top 9 by 18 ft.; and the portion uncovered contained at least half a million pounds of pure malachite. Also in handsome masses at Bembe, on the west coast of Africa · with the copper ores of Cuba; Chili; Australia.

Occurs in *Conn.*, at Cheshire. In *N. Jersey*, at Schuyler's mines, and still better at New Brunswick. In *Pennsylvania*, in the Blue Ridge, near Nicholson's Gap; near Morgantown, Berks County; at Cornwall, Lebanon Co., in good specimens; at the Perkiomen and Phenixville lead mines. In *Maryland*, between Taneytown and Newmarket, E. of the Monocacy; in the Catoctin Mts. In *Wisconsin*, at the copper mines of Mineral Point, and elsewhere. In *California*, at Hughes's mine, in Calaveras Co.

Green malachite admits of a high polish, and when in large masses is cut into tables, snuff-boxes, vases, etc.

Named from μαλαχή, *mallows*, in allusion to the green color.

Recent papers on cryst., v. Lang, Phil. Mag., IV. xxv. 432, xxviii. 502; v. Zepharovich, Ber. Ak. Wien, li. 112; Hessenberg Min. Not., Nos. iii. vi. vii.

751A. **Mysorin.** Massive. G.=2·62. Soft. Color blackish-brown, when pure; usually green or red, from mixture with malachite and red oxyd of iron. Fracture conchoidal.

Comp.—According to Thomson (Min., i. 601, 1836), Carbonic acid 16·70, oxyd of copper 60·75, sesquioxyd of iron (mechanically mixed) 19·50, silica 2·10, loss 0·95. Gives no water in a glass tube. Occurs at Mysore, in Hindostan. Although stated to be anhydrous, it may be an impure malachite.

751B. **Lime-Malachite** (Kalk-malachit *Zincken*, B. H. Ztg., i. 1842). Massive, reniform, botryoidal; structure fibrous and foliated. H.=2·5. Lustre silky. Color verdigris-green.

From Zincken's trials it is a hydrous carbonate of copper, with some carbonate and sulphate of lime and iron. From Lauterberg in the Harz.

752. AZURITE. Cæruleum, Lapis armenius pt., *Plin.*, xxxiii. 57. Cæruleum, *Germ.* Lasur, Berglasur pt., *Agric.*. 217, etc. Koppar-Lazur, Cuprum lazureum, Cæruleum montanum, *Wall.*, Min., 280, 1747. Bleu de montagne, Cuivre azurée, *Fr. Trl.* Wall., i. 506, 1753. Kupferlasur *Wern.* Bergblau *Germ.* *Abbé Fontana*, J. de Phys., ii. 1778 (with anal. making it a carbonate). Blue Carbonate of Copper, Blue malachite. Chessy Copper. $i\text{-}i \wedge I=139\ \ 46$

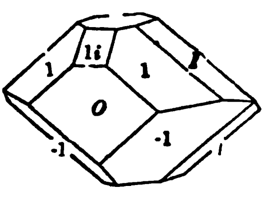
614



Cleavage: 2-ì rather perfect; $i\text{-}i$ less distinct; I in traces. Also massive, and presenting imitative shapes, having a columnar composition; also dull and earthy.

H.=3·5—4·25. G.=3·5—3·831. Lustre vitreous, almost adamantine. Color various shades of azure-blue, passing into berlin-blue. Streak blue, lighter than the color. Transparent—subtranslucent. Fracture conchoidal. Brittle.

Comp.—$2\,\dot{\mathrm{C}}\mathrm{u}\,\ddot{\mathrm{C}}+\dot{\mathrm{C}}\mathrm{u}\,\dot{\mathrm{H}}$=Carbonic acid 25·6, oxyd of copper 69·2, water 5·2=100. Analyses 1, Klaproth (Beitr., iv. 31, 1807); 2, Phillips (J. Roy. Institution, iv. 276); 3, Vauquelin (Ann. du Mus., xx. 1); 4, J. L. Smith (Am. J. Sci., II. xx. 250):

	$\ddot{C}$	$\dot{C}u$	$\dot{H}$
1. Turjinsk	24	70	6=100 Klaproth.
2. Chessy	25·46	69·08	5·46=100 Phillips
3. "	25·0	68·5	6·5 Vauquelin.
4. Phenixville	24·98	69·41	5·84=100·23 Smith.

Abbé Fontana obtained (l. c.) $\ddot{C}$ 31·42, $\dot{C}u$ 68·573, with only 1·007 of water.

Pyr., etc.—Same as in malachite.

Obs.—Occurs in splendid crystallizations at Chessy, near Lyons, whence it derived the name *Chessy Copper*. Also in fine crystals in Siberia; at Moldawa in the Bannat; at Wheal Buller, near Redruth in Cornwall; also in Devonshire and Derbyshire, England; in small quantities at Alston-Moor and Wanlockhead, etc.; at Porto Cabello, S. A.

Occurs in *Penn.*, at the Perkiomen lead mine, in indifferent specimens, associated with galenite, blende, and cerussite: at Phenixville, in crystals; at Cornwall, in crystals on red shale; near Nicholson's Gap, in the Blue Ridge. In *N. York*, near Sing Sing. In *N. Jersey*, near New Brunswick. In *Wisconsin*, at the old copper diggings near Mineral Point, in good crystals; also at the Bracken mine, in small but fine crystals. In *California*, Calaveras Co., at Hughes's mine, in crystals.

When abundant, azurite is a valuable ore of copper. When ground to an impalpable powder, it forms a blue paint of a bright tint; but it is of little value as a pigment, on account of its liability to turn green.

Alt.—Azurite occurs altered to malachite through the addition of carbonic acid.

752A. **Atlasite** *Breith.*, B. H. Ztg., xxiv. 310, 1865. A carbonate of copper from Chañarcillo in Chili, containing chlorine. It much resembles atacamite. It is coarse or fine columnar, with H.=3–4; G.=3·839–3·869; lustre vitreous to silky; color between celandine and emerald-green, nearer the first; streak verdigris-green. T. Erhard obtained for it (l. c.):

$\ddot{C}$ 16·48 $\dot{C}u$ 70·18 $\dot{H}$ 9·30 Cl 4·14 gangue 0·70=100·80,

whence he derives the formula $7(\dot{C}u^2\ddot{C}+\dot{H})+CuCl+3\dot{H}$, equivalent to 7 of malachite, 1 of a hydrous chlorid of copper.

According to this formula the mineral consists of 14 $\dot{C}u$, 10 $\dot{H}$, 1 Cu Cl. If now the Cu Cl is from mixed atacamite, it is combined with 3 $\dot{C}u\dot{H}$. The remainder, 11 $\dot{C}u$, 7 $\ddot{C}$, 7 $\dot{H}$, corresponds, excepting an excess of water, very nearly to the composition of azurite; 11 $\dot{C}u$, 7½ $\ddot{C}$, 3⅔ $\dot{H}$, would be precisely azurite. Atlasite may, therefore, be a mixture of about 3½ parts of azurite with 1 part of atacamite.

753. BISMUTITE. Bismutit *Breith.*, Pogg., liii. 627, 1841. Kohlensaures Wismuthoxyd, Wismuthspath, *Germ.* Bismuthite. Carbonate of Bismuth.

In implanted acicular crystallizations (pseudomorphous); also incrusting or amorphous; pulverulent.

H.=4–4·5; 3·5, specimens that have lost their lustre; earthy, 1·5. G.=6·86–6·909, Breith.; 7·67, from South Carolina, Rammelsberg. Lustre vitreous when pure; sometimes dull. Color white, mountain-green, and dirty siskin-green; occasionally straw-yellow and yellowish-gray. Streak greenish-gray to colorless. Subtranslucent—opaque. Brittle.

Comp.—According to Plattner's examinations (Pogg., liii. 727), it is a carbonate of bismuth, containing some iron and copper (perhaps a carbonate of each), and also sulphuric acid.

Rammelsberg examined specimens from South Carolina, probably of this species, and obtained the formula $3(\ddot{\bar{B}}i\ddot{C}+\dot{H})+\ddot{\bar{B}}i\dot{H}$ ($=\ddot{\bar{B}}i^4\ddot{C}^3\dot{H}^4$)=Oxyd of bismuth 90·1, carbonic acid 6·4, water 3·5=100. Analyses: 1, Rammelsberg (Pogg., lxxvi. 564, 1849); 2, 3, Genth (Am. J. Sci., II xxiii. 427):

	$\ddot{C}$	$\ddot{\bar{B}}i$	$\dot{H}$
1. Chesterfield Dist.	6·56	90·00	3·44=100 Ramm.
2. " "	7·04	89·05	3·91=100 Genth.
3. " "	7·30	87·67	5·03=100 Genth.

Pyr., etc.—In the closed tube decrepitates and gives off water. B.B. fuses readily, and on charcoal is reduced to bismuth, and coats the coal with yellow oxyd of bismuth. Dissolves in nitric acid, with slight effervescence. Dissolves in muriatic acid, affording a deep yellow solution.

Obs.—Bismutite occurs at Schneeberg and Johanngeorgenstadt, with native bismuth, and near Hirschberg in Russian Voigtland, with brown iron ore, native bismuth, and bismuthinite; at Joachimsthal; near Baden; also in the gold district of Chesterfield, S. C., at Brewer's mine, in porous yellowish masses, sometimes reddish from oxyd of iron; surface of fracture white and vitreous, resembling somewhat calamine; in Gaston Co., N. C., in yellowish-white concretions.

753A. With the bismutite of Joachimsthal occurs another bismuth carbonate, in thin longish crystals, vitreous, siskin-green to clove-brown, translucent. It contains, according to Lindacker (Vogl's Min. Joach., 168), oxyd of bismuth, carbonic acid, water, silica: effervesces with acids, and B.B. gives bismuth reactions.

754. LIEBIGITE. *J. L. Smith*, Am. J. Sci., II. v. 336, 1848, and xi. 259. Uran-Kalk-Carbonat *Vogl*, Jahrb. G. Reichs., iv. 221, 1853.

In mammillary concretions, or thin coatings; cleavage apparent in one direction.

H.=2—2·5. Lustre of fracture vitreous. Color beautiful apple-green. Transparent.

Comp.—$\dddot{\bar{U}}\ddot{C}+\dot{Ca}\ddot{C}+20\dot{H}$=Carbonic acid 11·1, oxyd of uranium 36·2, lime 7·1, water 45·6; or $2\dot{Ca}\ddot{C}+\dddot{\bar{U}}^2\ddot{C}+36\dot{H}$, Ramm.,=$\ddot{C}$ 9·02, $\dddot{\bar{U}}$ 39·12, $\dot{Ca}$ 7·67, $\dot{H}$ 44·19=100. Analysis by J. L. Smith (l. c.):

$\ddot{C}$ 10·2 $\dddot{\bar{U}}$ 38·0 $\dot{Ca}$ 8·9 $\dot{H}$ 45·2

Pyr., etc.—In a matrass yields much water and becomes yellowish-gray. At redness it blackens, without fusing, and on cooling *returns to an orange-red* color. At a higher heat it blackens, and remains so on cooling. With borax it gives a yellow glass in the outer flame, and a green glass in the inner. Dissolves readily in dilute acids with effervescence, and affords a yellow solution, with the reaction of uranium and lime

Obs.—Occurs with medjidite on pitchblende, near Adrianople, Turkey; also at Johanngeorgenstadt and Joachimsthal. Dr. Smith states that both the lime and uranium of this salt are derived from the pitchblende.

A related mineral from Elias mine, near Joachimsthal, has been examined by Vogl and J. Lindacker (Jahrb. G. Reichs., iv. 221, 1853). It occurs in scaly aggregations on pitchblende, has a siskin-green color, and a pearly lustre on a cleavage-face; subtransparent to translucent; H.=2·5—3. B.B. on charcoal infusible; with borax and salt of phosphorus the reaction of uranium. Dissolves with effervescence in sulphuric acid, a white deposit being thrown down; solution in sulphuric and muriatic acids green, in nitric acid yellow.

Composition, according to J. Lindacker (l. c.), $\dot{U}\ddot{C}+\dot{Ca}\ddot{C}+5\dot{H}$=$\ddot{C}$ 24·18, $\dot{U}$ 37·03, $\dot{Ca}$ 15·55, $\dot{H}$ 23·34=100. Mean of three analyses:

$\ddot{C}$ 23·86 $\dot{U}$ 37·11 $\dot{Ca}$ 15·56 $\dot{H}$ 23·34=99·87.

These carbonates are produced by the action of carbonated waters on the sulphates.

755. VOGLITE. Uran-Kalk-Kupfer-Carbonat *Vogl*, Jahrb. G. Reichs., iv. 222, 1853. Voglit *Haid.*, ib., 223.

In aggregations of crystalline scales. Scales rhomboidal somewhat like gypsum, with angles of 100° and 80°, Haid.

Lustre pearly. Color emerald-green to bright grass-green. Dichroic.

Comp.—$2\dot{U}\ddot{C}+2\dot{Ca}\ddot{C}+\dot{Cu}^3\ddot{C}^2+14\dot{H}$, Lindacker, from his analysis (Jahrb. G. Reichs., iv 222):

$\ddot{C}$ 26·41 $\dot{U}$ 37·00 $\dot{Ca}$ 14·09 $\dot{Cu}$ 8·40 $\dot{H}$ 13·90=100.

Pyr., etc.—In the closed tube blackens and yields water. B.B. in the platinum forceps infu sible, colors the flame deep green; if moistened with muriatic acid the flame is momentarily blue With soda on charcoal yields metallic copper. With borax in O.F. the bead is yellow while hot and reddish-brown on cooling; in R.F. green while hot and clouded when cold. Soluble in acids with effervescence.

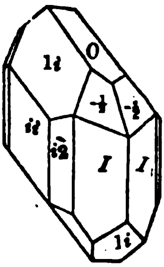
Obs.—From the Elias mine, near Joachimsthal, implanted on pitchblende.

---

8. OXALATES.

756. WHEWELLITE. Oxalate of Lime *H. T. Brooke*, Phil. Mag., III. xvi. 449, 1840. Oxacalcite *Shepard*, Min., 111, 1844. Whewellite *B. & M.*, Min., 623, 1852.

615



Monoclinic. $C=72°\ 41'$, $I \wedge I=100°\ 36'$, $O \wedge 1\text{-}\grave{\imath}=127°\ 25'$; $a:b:c=1{\cdot}5745:1:1{\cdot}1499$. Observed planes as in the annexed figure. $O \wedge I=103°\ 14'$, $O \wedge 1\text{-}i=109°\ 28'$, $O \wedge -\frac{1}{2}=141°\ 6'$, $I \wedge i\text{-}\grave{\imath}=129°\ 42'$. Cleavage parallel with O; less perfect parallel with I, and the longer diagonal. All the planes bright except I and $-\frac{1}{2}$, which are vertically striated. Twins: composition-face $1\text{-}i$.

H.=2·5—2·75. Lustre like that of sulphate of lead. Very brittle. Fracture conchoidal.

This species, an oxalate of lime, was observed by Brooke in crystals from a tenth to a fourth of an inch broad on calc spar; the locality of the spar is not known.

The name *oxacalcite* proposed by Shepard is badly formed, and should yield to Brooke & Miller's, after Prof. Whewell of Cambridge.

757. THIERSCHITE *Liebig*, Ann. Ch. Pharm., lxxxvi. 113, 1853. An oxalate of lime, occurring as a grayish, warty, and somewhat opaline incrustation, about a line thick, on the marble of the Parthenon, Athens. A complete analysis has not yet been made. Its origin is attributed to the action of some kind of vegetation on the marble. It is probably identical with whewellite. Named after F. v. Thiersch, the discoverer.

758. HUMBOLDTINE Faser Resin (Honigsteinsaurer Eisen?) *Breith.*, Char., 75, 1820. Humboldtine, Oxalsaures Eisen, *M. de Rivero*, Ann. Ch. Phys., xviii. 207, 1821. Eisen-Resin *Breith.*, Gilb. Ann., lxx. 426, 1822. Oxalit *Breith.*, Char., 1823. Humboldtit *Leonh.*, Handb., 789, 1826.

In capillary forms; also botryoidal and in plates, or earthy; structure fibrous or compact.

H.=2. G.=2·13—2·489. Dull or slightly resinous. Color yellow. Fracture uneven, earthy. Acquires negative electricity by friction, when insulated.

COMP.—$2\,\dot{F}e\,\ddot{\bar{C}}+3\,\dot{H}$=Oxalic acid 42·1, protoxyd of iron 42·1, water 15·8=100. Analysis by Rammelsberg (Pogg., xlvi. 283):

$\dot{F}e$ 41·13 Oxalic acid 42·40 (loss) 16·37=100.

Mariano de Rivero obtained (l. c.) Oxalic acid 46·14, and protoxyd of iron 53·86, with no water

Rammelsberg (Pogg.. liii. 631, 1841) has confirmed his former analysis, and shown that the iron is all protoxyd.

Pyr., etc.—In the closed tube yields water, turns black, and becomes magnetic. B.B. on charcoal is colored at first black, but later red, and with the fluxes reacts for oxyd of iron.

Obs.—Occurs in brown coal at Koloseruk, near Bilin, Bohemia; at Gross-Almerode, in Hessia, and according to T. S. Hunt, at Kettle Point, in Bosanquet, Canada, as an incrustation on black shales, soft, earthy, sulphur-yellow (Logan's Report, 1850, 1863).

VI. HYDROCARBON COMPOUNDS.

ARRANGEMENT OF THE SPECIES.

I. SIMPLE HYDROCARBONS.

1. Marsh-Gas Series.—*General formula* Θ_nH_{2n+2}.

1. NAPHTHA GROUP.—Liquids.

761.	Tetrylic Hydrid	Θ_4H_{10}	764.	Heptylic Hydrid	Θ_7H_{16}
762.	Pentylic Hydrid	Θ_5H_{12}	765.	Octylic Hydrid	Θ_8H_{18}
763.	Hexylic Hydrid	Θ_6H_{14}	766.	Nonylic Hydrid	Θ_9H_{20}

There are also in nature the gaseous members of the series, ΘH_4, or Marsh-gas (Methylic Hydrid); Θ_2H_6, or Ethylic Hydrid; Θ_3H_8, or Tritylic Hydrid.

2. BETA-NAPHTHA GROUP.—Probably polymeres of the species of the Naphtha group by a common multiple; boiling point 7°–8° higher than for corresponding species of the Naphtha group.

767.	n Θ_4H_{10}	769.	n Θ_6H_{14}	771.	n Θ_8H_{18}
768.	n Θ_5H_{12}	770.	n Θ_7H_{16}		

3. SCHEERERITE GROUP.—Solid, or butter-like, and tasteless.

772.	Scheererite	n ΘH_4	773.	Chrismatite	n Θ_2H_6

2. Ethylene Series or Olefines.—*General formula* Θ_nH_{2n}.

4. PITTOLIUM GROUP.—Liquids.

774.	Decatylene	$\Theta_{10}H_{20}$	776.	Dodecatylene	$\Theta_{12}H_{24}$
775.	Endecatylene	$\Theta_{11}H_{22}$	777.	Decatritylene	$\Theta_{13}H_{26}$

5. PARAFFINE GROUP.—Solids, wax-like; tasteless.

778. Urpethite
779. Hatchettite
780. Ozocerite
781. Zietrisikite

Appendix.—782. Elaterite
783. Settling Stones Resin

3. Camphene Series.—*General formula* Θ_nH_{2n-4}.

6. FICHTELITE GROUP.—Solid; without taste or smell; easily crystallizable.

784.	Fichtelite	n $\Theta_{10}H_{16}$	786. Dinite
785.	Hartite	n $\Theta_{12}H_{20}$	787. Ixolyte

4. Benzole Series.—*General Formula* $\Theta_n H_{2n-6}$.

7. BENZOLE GROUP.—Liquids.

788. Benzole	$\Theta_6 H_6$	791. Cumole	$\Theta_9 H_{12}$
789. Toluole	$\Theta_7 H_8$	792. Cymole	$\Theta_{10} H_{14}$
790. Xylole	$\Theta_8 H_{10}$		

8. KÖNLITE GROUP.—Solid.

793. Könlite	$n\,\Theta_6 H_4$

5. Naphthalin Series.—*General formula* $\Theta_n H_{2n-12}$.

794. Naphthalin	$\Theta_{10} H_8$

Appendix.—795. Idrialite.

II. OXYGENATED HYDROCARBONS.

1. GEOCERITE GROUP.—Ratio of Θ, H = 1 : 2. Wax-like.

796. Geocerite	$\Theta_{28} H_{56} \Theta_2$	797. Geomyricite	$\Theta_{34} H_{68} \Theta_2$

2. SUCCINITE GROUP.—Ratio of Θ, H = 5 : 8 to 5 : 8½. Insoluble in alcohol and ether.
[Below, the ratio of Θ, H, Θ is given for the species, and for better comparison the carbon is made 40, without writing out a formula.]

798. Copalite	40 : 64 : 1	802. Ambrite	40 : 66 : 5
799. Succinite	40 : 64 : 4	803. Bathvillite	40 : 68 : 4
800. Walchowite	40 : 64 : 3½ ?	804. Torbanite	? 40 : 68 : 2
801. ? Bucaramangite	40 : 66 : 2½		

3. XYLORETINITE GROUP.—Ratio of Θ, H = 5 : 8 to 5 : 8½. Largely soluble in ether, and some species in alcohol.

805. Xyloretinite	40 : 64 : 4	806. Leucopetrite	40 : 67½ : 2½
807. Euosmite	40 : 68 : 2½		

4. SCLERETINITE GROUP.—Ratio of Θ, H = 5 : 7. Insoluble in alcohol and ether.

808. Scleretinite	40 : 56 : 4

5. PYRORETINITE GROUP.—Ratio of Θ, H = 5 : 7 to 5 : 6½. Soluble in alcohol or ether.

809. Jaulingite (p. 800)	40 ? : 60 : 4½	811. Rochlederite	40 : 56 : 6
810. Pyroretinite	40 : 56 : 4	812. Schlanite	40 : 52 : 3½
810A. Reussinite	40 : 56 : 3	813. Guyaquillite	40 : 52 : 6

6. Ratio of Θ, H = 5 to 5½ or less. Insoluble in alcohol or ether.

814. Middletonite	40 : 44 : 2	815. Stanekite	? 40 : 44 : 6
816. Anthracoxenite	40 : 38 : 7½		

7. DYSODILE GROUP.—Containing sulphur in place of part of the oxygen.

817. **Tasmanite** 40 : 64 : 3 818. **Dysodile**

Appendix.—819. **Hircite.** 820. **Baikerinite.**

III. ACID OXYGENATED HYDROCARBONS.

821. **Butyrellite**	$\Theta_{32}\,H_{64}\,\Theta_4$
822. **Geocerellite** (Geoceric acid)	$\Theta_{28}\,H_{56}\,\Theta_4$
823. **Brücknerellite** (Georetinic acid)	$\Theta_{24}\,H_{44}\,\Theta_8$
824. **Succinellite** (Succinic acid)	$\Theta_4\,H_6\,\Theta_4$
825. **Retinellite**	$\Theta_{21}\,H_{26}\,\Theta_3$
826. **Dopplerite**	? $\Theta_{10}\,H_{12}\,\Theta_6$
827. **Melanellite**	$\Theta_{12}\,H_{10}\,\Theta_4$

IV. SALTS OF ORGANIC ACIDS.

828. **Mellite**	$\dddot{\bar{A}}l\,\overline{M}^3+18\,\dot{H}$	$\Theta_4\,\Theta_3\|\Theta_3\|\beta\bar{A}l+6$ aq
829. **Pigotite**		
829A. Organic salts of iron		Undetermined

V. NITROGENOUS HYDROCARBONS.

Species undetermined.

Appendix to Hydrocarbons.

830. **Asphaltum** 831. **Mineral Coal**

The formulas above are all written on the new system. If the number connected with H is halved in each case, and the barred capitals are replaced by common capitals, they will then conform to the old system.

The *native* hydrocarbons are very imperfectly known. Most of the kinds hitherto recognised in mineralogy are more analogous to rocks than minerals. *Amber*, for example, instead of being a species, is a mixture of four or more species, as Berzelius long since pointed out, and only two of the number have thus far been investigated. The presence of *succinic acid*, one of these two, is spoken of as an essential constituent and distinguishing feature of amber: and this it is; but only in the way that feldspar is a constituent of granite. Petroleum, Asphaltum, and the various kinds of mineral resins and wax are similar mixtures, in the light of chemistry, as has been shown by many investigators. But still the true line of investigation is so little appreciated that new resins or asphalts are from time to time brought forward as species in mineralogy upon characters that only prove them to be mixtures. And chemistry, while working toward a better state of this department of mineralogy, often fails in its researches to distinguish educts (native ingredients) from products.

The facts in the case, and the true idea of the science, sustain the course of the author in here removing amber from mineralogical species, and calling, not amber, but the insoluble resin which constitutes four-fifths of its mass, *succinite;* and in endeavoring to apply the same method throughout the hydrocarbon section. Much more investigation is demanded before satisfactory results can in all cases be attained. But by pursuing the subject in the way here recognized, the section will ultimately become an exhibition of the actual *species* of hydrocarbons in nature and thus be elevated to the same level with other parts of the science.

I. SIMPLE HYDROCARBONS.

NAPHTHA AND BETA-NAPHTHA GROUPS.

Syn. of Naphtha and Petroleum. Νάφθα. *Strabo*, xvi. i. § 15, *Dioscor.*, i. 101 Naphtha, Bitumen liquidum candidum, *Plin.*, ii. 109, xxxv. 51. Naphtha flos bituminis *Agric.* Ort. Caus. Subt., 45, 1544. Liquidum bitumen, nunc vocatur Petroleum, *Agric.*, Nat. Foss., 222, 1546. Erdöl, Bergöl, Steinöl, *Germ.* Mineral Oil. Kerosene. Bitume liquide *Fr.*

The liquids or oils of the Naphtha and Beta-naphtha groups occur as constituents of the lighter kinds of *petroleum*. The other native constituents, and the most abundant, are the oils of the Ethylene series and the paraffins; and the proportion of ethylenes increases with the increase of density or viscidity. (See Pittolium Group, and Paraffin.)

The general formula is $\Theta_n H_{2n+2}$, or that of the Marsh-gas series. The specific gravities, boiling points, and vapor densities increase with the increase in the atomic number, or the value of *n* in the above formula, as shown in the following table, which contains also the percentage composition:

Naphtha Group.

		C	H	Boiling T.	G.	Vapor Density found
761.	Tetrylic Hydrid	$\Theta_4 H_{10}$=82·80	17·20	0°0?	0·600	2·110
762.	Pentylic Hydrid	$\Theta_5 H_{12}$=83·33	16·67	30·2	0·640	2·538
763.	Hexylic Hydrid	$\Theta_6 H_{14}$=83·72	16·28	61·3	0·676	3·053
764.	Heptylic Hydrid	$\Theta_7 H_{16}$=84·0	16·0	90·4	0·718	3·547
765.	Octylic Hydrid	$\Theta_8 H_{18}$=84·21	15·79	119·5	0·737	3·992
766.	Nonylic Hydrid	$\Theta_9 H_{20}$=84·38	15·62	150·8	0·756	4·460

Beta-Naphtha Group.

		Boiling T.	G.	Vapor Density.
767.	$\Theta_4 H_{10}$	8—9°	0·611	
768.	$\Theta_5 H_{12}$	37·0	0·645	2·514
769.	$\Theta_6 H_{14}$	68·5	0·689	3·038
770.	$\Theta_7 H_{16}$	98·1	0·730	3·551
771.	$\Theta_8 H_{18}$	127·6	0·752	3·990

The names *Amylic Hydrid*, *Caproylic*, *Œnanthylic*, *Caprylic*, *Pelargonylic*, are often used for the above 762 to 766. Those in the table are derived from the Greek for 4, 5, 6, 7, 8, 9, and were proposed by Gerhardt.

The constitution of petroleum has been investigated by various chemists, among whom the most prominent are Pelouze and Cahours (C. R., liv. 124, lvi. 505, lvii. 62), and C. M. Warren (Mem. Am. Ac. Boston, II. ix. x., Am. J. Sci., II. xl. xlv. xlvi.). Pelouze and Cahours continue the naphtha series to $\Theta_{15} H_{32}$, and state evidence of the existence of still higher members. But Warren arrived at the conclusion that the naphtha or marsh-gas series terminates with $\Theta_9 H_{20}$, and that the oils of higher density and atomic numbers belong to the ethylene series ($\Theta_n H_{2n}$). Moreover, Warren brought out the fact that there was a *second* naphtha group, differing from the other in its higher boiling points—the *Beta-naphtha* group above. This chemist also determined with great exactness the boiling points of the two groups, and found that in both there was the common difference of about 30°C. for successive terms in the series (or for a difference of CH_2); but that the boiling points in the second series were about 8° higher correlatively than those of the 1st series, as the tables show.

The specific gravities and vapor densities for 761 are from Ronalds. Those of the others, 762 to 772, are from Warren, excepting the vapor densities of 762, 763. The vapor density of 767 has not yet been determined. Warren's specific gravities were taken at 0° C.

Ronalds has observed that the gaseous compounds of the marsh-gas series C_2H_6 and C_3H_8 (2d and 3d terms in the marsh-gas series) also exist in connection with petroleum. *Marsh-gas* itself, the *first* term in the series CH_4, is a very common gas of coal beds and bituminous deposits, as well as of modern marshes.

Petroleum passes by insensible gradations into *pittasphalt* or *maltha* (viscid bitumen); and the latter as insensibly into *asphalt* or solid bitumen.

Petroleum occurs in rocks or deposits of nearly all geological ages, from the Lower Silurian to the present epoch. It is associated most abundantly with argillaceous shales and sandstones, but is found also permeating limestones, giving them a bituminous odor, and rendering them sometimes a considerable source of oil. From these oleiferous shales and limestones the oil often exudes, and appears floating on the streams or lakes of the region, or rises in oil springs. It also exists collected in subterranean cavities in certain rocks, whence it issues in jets or fountains whenever an outlet is made by boring. These cavities are situated mostly along the course of gentle anticlinals in the rocks of the region; and it is therefore probable, as has been suggested, that they originated for the most part in the displacements of the strata caused by the slight uplift. The oil which fills the cavities has ordinarily been derived from the subjacent rocks; for the strata, in which the cavities exist, are frequently barren sandstones. The conditions required for the production of such subterranean accumulations would be therefore (as others have explained) a bituminous oil-bearing, or else oil-producing, stratum at a greater or less depth below; cavities to receive the oil; an overlying stratum of close-grained shale or limestone, not allowing of the easy escape of the naphtha vapors.

If the oil exists ready formed in the rocks, only a slight heat above that common to the rocks would be needed to expel the oil slowly from below. And, without heat, as Hunt states, the oil might be expelled through the pressure of superincumbent waters from the oil-bearing shales or clays, and would rise and occupy the cavities because so light as to float on the waters.

But if the oil-producing bed contained not the oil ready made, but only hydrocarbonaceous matters that may afford it on destructive distillation, the oil would have required considerable heat for its production.

In the Caspian and Rangoon naphtha regions the oleiferous clayey deposits are nearly or quite superficial, and the oil, a viscid kind, exudes readily into pits made for collecting it.

In the United States liquid oil occurs in the *Lower Silurian*, in the "Bird's-eye" limestone of Rivière à la Rose (Montmorenci), Canada, and of Watertown, N. Y., in drops in fossil coral; and in the Trenton limestone at Pakenham, Canada, the cavities of large Orthocerata sometimes hold several ounces (T. S. Hunt, Am. J. Sci., II. xxxv. 166, 1868); on Grand Manitoulin Id., where a spring affording it arises from the Utica shale, the source possibly the subjacent limestones; at Guilderland, near Albany, from the Hudson River group, as observed in a spring by Beck; quite freely in limestone and shale near Chicago; far more so in Kentucky, in the Cumberland oil region, the wells, "from which tens of thousands of barrels of oil have flowed" (Newberry), descend 200 ft. into the Blue Limestone, in which there are bituminous shaly strata overlaid by sheets of thin-bedded compact limestone; these features prevail from Lincoln and Casey Cos., through Adair and Russell, Cumberland and Clinton Cos., Ky., and Overton and Jackson Cos., Tenn.

In the *Upper Silurian* traces have been observed in the Niagara limestone and the Medina red shales; at Gaspé, Canada, in a Lower Helderberg limestone, on Silver Brook, etc.; near Chicago, so abundant in a limestone as to ooze out, and the rock may be made to burn, owing to its presence.

In the *Lower Devonian*, the Corniferous limestone is regarded by Hunt as the source of the oil of Enniskillen, Canada, where there are large areas covered by the half-inspissated bitumen. Hunt states (l. c.) that at Rainham, Canada, on L. Erie, shells of *Pentamerus aratus* are sometimes filled with petroleum; and that in other places in the region imbedded corals, *Heliophyllum* and *Favosites*, have, in certain of the layers, their cells full of oil (while in other layers it is absent from the corals), and in quarrying, the oil flows out and collects on the water of the quarry; and at Gaspé, Lower Devonian sandstones afford oil springs and give rise to beds of thickened petroleum, and the chalcedonic geodes of a trap dyke, intersecting the sandstone, sometimes contain petroleum. In the *Middle Devonian*, the Black shale, or Genesee slate, is supposed by many geologists to be the principal source of the oil of Pennsylvania, the Kenawha valley, and other parts of eastern Virginia, and of Ohio and Michigan; but J. P. Lesley attributes much of the oil of western Pennsylvania to the Subcarboniferous. Near Fredonia, Chatauque Co., and at Rockville, Alleghany Co., oil is found in connection with Chemung rocks, or the Upper Devonian (Hall).

A little oil has been observed in connection with Triassic shales at Southbury, Conn. The oil of southern California proceeds from Tertiary shales. On Trinidad a thick oil, with asphalt, occurs in connection with lignite and other vegetable remains in the shales constituting the upper part of the Tertiary; and specimens of the vegetable material, partly changed to oil and penetrated by [illegible] and having its cells looking as if they had been corroded, as a result of the change are described by Wall (Q. J. G. Soc, xvi. 460).

Noted foreign localities are 3 m. from Ye-nan-gyoung (*Fetid-water-rivulet*), Burmah (and exported from Rangoon), where there are about 100 wells, from 180 to 300 feet deep, each lined with horizontal timber, but not all now worked (Oldham); the peninsula of Apcheron on the western shore of the Caspian, at Bakee, where naphtha exudes from argillaceous and calcareous beds, especially the former, of the Middle Tertiary (Abich), and where it has long been used for burning in lamps and for cooking; near the centre of the region the light and pure naphtha oil is obtained, while along its borders the oil is a thicker petroleum, or passes into an asphalt, and solid masses of this asphalt are often seen floating in the Caspian; on the island of Tscheleken, near the eastern coast of the Caspian, in Balkan Bay; on the banks of the Kuban, promontory of Taman, east side of isthmus between the Azof and Black Sea; near the river Betchora, in the government of Archangel, Russia; near the village of Amiano, in Parma, Italy, whence enough was formerly obtained to light the streets of Genoa; at Zante, one of the Ionian islands (ancient Zacynthus), which has furnished oil for more than 2,000 years, its petroleum spring having been mentioned by Herodotus. Pliny mentions the oil of a spring at Agrigentum, Sicily, and states that it was collected and used for burning in lamps, as a substitute for oil. He distinguishes this oil from naphtha, which he says was too light and inflammable for such a use. Of naphtha, he mentions a locality in "Parthia" (about the sources of the Indus). Oil is found also near the city of Mexico, and on the river Lagun.

The oil spring of Cuba, Alleghany Co., N. Y., called the Seneca Oil Spring, long known, was described by Prof. Silliman in 1833 (Am. J. Sci., xxiii. 97) as a dirty pool, about 18 ft. across, covered with a film of oil, which was skimmed off from time to time for medicinal purposes. The so-called "Seneca oil," sold at the time in the shops (and from which he often distilled naphtha for preserving potassium), he observes was not from this spring (around which the Seneca Indians then had a reserve of a square mile), but, as he was told, from Oil Creek, Venango Co., Pa., about 100 m. from Pittsburg. *Seneca Lake* has oil on its surface in some parts, and it is said to have given the name to the oil; but whether this is the true source, or whether it came from its being collected and sold by the Seneca Indians, is not clear. Hildreth in 1833 (ib., xxiv. 63), and later in 1836 (ib., xxix. 86, 121, 129), gave an account of the salt wells of the Little Kenawha valley, which then afforded, he says, 50 to 100 gallons a year. He also speaks, in 1833, of a well 475 ft. deep, 30 m. N. of Marietta, Ohio, which, when first opened, discharged at intervals of 2 to 4 days, for 3 to 6 hours each time, throwing out 30 to 60 gallons of oil at each "eruption," but was then yielding only a barrel a week. In 1840 a *spouting* well of oil, at Burksville, Kentucky, was described (ib., xxxix. 195); the well was bored for salt, and 200 ft. down a "fountain of pure oil was struck, which was thrown up more than 12 ft. above the surface of the earth," emitting, according to the estimate, 75 gallons a minute; it "continued to flow for several days successively," but then failed; and efforts to bring it into action again, or find another, were not successful. The petroleum of Enniskillen, Canada, was mentioned in 1844 by Mr. Murray, in the Canada Geological Report for 1846; and in 1857 wells were sunk for the collection of it. In 1859, on Oil Creek, Venango Co., Pa., a boring for salt, but 75 feet deep, let out the first *fountain* of oil of that now famous oil-region. For many weeks it discharged 1,000 gallons per day.

The *origin* of petroleum, including the lighter as well as heavier kinds, has been attributed by some to the decomposition of vegetable substances alone (Bischof, etc.); but it is now generally admitted that it has come from animal as well as vegetable, as urged by Dufrénoy (Min., iv. 602, 1859), J. S. Newberry (Ohio Agric. Rep., 1859), and T. S. Hunt (Can. Nat., vi. 241, 1861. Am. J. Sci., II. xxxv., Ch. News, 1863).

The conditions favorable to the formation of naphtha, as shown by the characteristics of the deposits in which it is found native, are the following: (1) the diffusion of organic material through a fine mud or clay; (2) the material in a very finely divided state; and (3), as a consequence of the preceding, the atmosphere excluded as far as possible from the material undergoing decomposition. There is reason to believe that no more heat was required than what was afforded by the natural climate or temperature of the region and the process of fermentation.

Shales, the most common oil-bearing rocks, were originally the fine mud of deep or shallow seas; and the limestones were the same, only the mud was calcareous in nature, like the coral mud of many a coral lagoon, as the author has elsewhere described after personal examination. These shales ordinarily contain few fossils of any kind, and very rarely distinct vegetable remains. It may be questioned whether tough fucoids (sea-weeds), or the branches and leaves of ordinary plants imbedded in such clays, would ever become so subdivided or disorganized as to make the requisite emulsion with the mud free from any vegetable forms; and it is more probable that the vegetable material present was either delicate water-plants, or was derived from abundant infusorial or microscopic vegetable life. The limestones, on the contrary, are sometimes full of fossils, but these are animal; and, as the solid parts which make the fossils are to a large extent ground up to make the mud that becomes the limestone, the organic material these hard parts contain, as well as that of the fleshy parts and oils, would be diffused through the mud or earth in the very condition demanded.

The light native oils do not occur in coal beds, which were made from thick beds of vegetable debris.

In the above-mentioned circumstances, with the deposits under pressure from superincumbent beds, the atmospheric air almost totally excluded, the organic material might undergo decomposition through the reactions of its own elements alone. (See on this subject, and the reactions mentioned below, Bischof, Chem. G., ii. 1853, T. S. Hunt, Can. Nat. and Ch. News, l. c.) The average composition of dry wood (the ash and nitrogen excluded) is represented by $\text{Ȼ}_6 H_9 \Theta_4 =$ Carbon 49·66, hydrogen 6·21, oxygen 44·13=100. Taking two parts, we have $\text{Ȼ}_{12} H_{18} \Theta_8$. If now the oxygen combines with carbon to form carbonic acid, $4\,\text{Ȼ}\Theta_2$ will thus be removed, leaving $\text{Ȼ}_8 H_{18}$, which is the composition of one of the species of the naphtha group, the fifth, on p. 720. But $\text{Ȼ}_8 H_{18}$, or $\text{Ȼ}_{32} H_{72}$, its multiple by 4, corresponds also to $3(\text{Ȼ}_6 H_{14}) + \text{Ȼ}_8 H_{18} + \frac{1}{2}(\text{Ȼ}_{12} H_{24})$, the first two members light naphtha oils, and the last an ethylene, a composition much like that of Pennsylvania petroleum. The decomposition might not be as simple as here taken, as $\frac{1}{2}$ to 1 p. c. of nitrogen is also present, and there would also be some animal material. But the illustration is still satisfactory. That no water ($H_2\Theta$) would be formed from the elements of the organic material is apparently indicated by the fact that this would make an excess of carbon or a deficiency of hydrogen. From Chevandier's numerous analyses (Ann. Ch. Phys., III. x. 129), the average composition of dry wood is carbon 51·21, hydrogen 6·24, oxygen 41·45, nitrogen 1·10, corresponding, if the nitrogen is not counted, to $\text{Ȼ}_{12} H_{17\cdot5} \Theta_{7\cdot5}$; from which the resulting oils might be nearly the same as above.

Were there less confinement by superincumbent beds or earthy material, part of the hydrogen might be lost by combining with the carbon and escape as marsh gas ($\text{Ȼ}H_4$), and thus determine the formation of the thicker oils; or else of the solid insoluble hydrocarbons, more or less oxygenated, which make many shales a rich source of oil on distillation.

With the air not well excluded, as in the case of all thick beds of vegetable debris, such as have formed peat and the various kinds of coal, the decompositions would be more complex: outside oxygen carrying off, it may be, part of the hydrogen (as water), and of the carbon (as carbonic acid). Thus $\text{Ȼ}_{12} H_{18} \Theta_8$ (composition of wood) may change to $\text{Ȼ}_{12} H_{14\cdot5} \Theta_6$, the average composition of *peat;* or to $\text{Ȼ}_{12} H_{12} \Theta_{3\cdot5}$=Carbon 67·92, hydrogen 5·66, oxygen 26·42=100, a medium brown coal (or lignite); or $\text{Ȼ}_{12} H_{9\cdot75} \Theta_{0\cdot87}$=Carbon 85·88, hydrogen 5·82, oxygen 8·30=100, Wigan cannel coal, etc.

Marsh-gas ($\text{Ȼ}H_4$) is a common gas of marshy places and of Artesian wells, and so also, though less abundantly, carbonic acid (Bischof). The distillation of wood will afford the solid hydrocarbons of the paraffin group; Reichenbach, in his discovery of paraffin, obtaining it from the wood of the *Fagus sylvatica*. Dr. J. S. Newberry states (priv. contrib.) that off the shores of Lake Superior, at Marquette, he observed bubbles of gas coming from the bottom to the surface, which proved to be carburetted hydrogen; and also, now and then, drops of oil slowly rising, and finally spreading over the surface, which oil proved on examination to be a kind of petroleum. Although the *vegetable* origin of the oil was not certain, it seemed to be altogether probable. On the island of Trinidad the oil-producing beds are clayey beds in the Tertiary, containing remains of plants, and Wall states (Q. J. G. Soc., xvi. 460) that there is full evidence that the liquid and solid bitumen was produced at the ordinary temperature and condition of climate in the occurrence of numerous specimens of the vegetable matter in process of transformation, which have, as a consequence, the organic structure more or less obliterated.

In the change of animal matters to oil, there is more nitrogen present to give complexity to the mutual reactions. But when the material is animal oils, there are only carbon, hydrogen, and oxygen, as in the case of vegetation. In such oils there are nearly the proportions $\text{Ȼ}_{18} H_{34} \Theta_2$. In the case of such a compound (oleic acid), the forming of carbonic acid from the oxygen would separate $\text{Ȼ}\Theta_2$, and leave $\text{Ȼ}_{17} H_{34}$, of the ethylene ratio; in that of $\text{Ȼ}_{17} H_{34} \Theta_2$ (margaric acid) the same would leave $\text{Ȼ}_{16} H_{34}$, or a combination of marsh-gas oils. Warren and Storer have obtained (Mem. Am. Ac. Boston, ix. 177, Am. J. Sci., II. xlii. 250) from the destructive distillation of a fish-oil, after its saponification by lime, all the compounds above enumerated of the Naphtha group, besides others of the ethylene and benzole series.

Dr. Newberry has observed that cannel coal sometimes shows by its animal fossils that part of its oily products may be of animal origin (Am. J. Sci., II. xxiii. 212, 1857), instancing a case in Ohio in which the coal contained fossil fishes. He also remarks on the disagreeable smell of some limestone oil, and attributes it to its animal origin. Dufrénoy, in his Mineralogy (iv. 602, 1859), gives prominence to the fact that remains of fishes are common in oil-producing shales and to the view that they are the source of the oil, mentioning as examples the black shales in the Coal formation at Saarbruck in Prussia, and Ygornay near Autun in France; the Permian (Zechstein) at Mansfeld; grayish limestone, in the Lias, at Doubs; and grayish shale, in the

Middle Tertiary, at Menat, 30 m. from Clermont, France; all of which abound in the remains of fishes. The shales adjoining the Albertite of Nova Scotia have been mentioned as another example of this kind. The black semibituminous or coaly shales of the Triassic of the Connecticut valley contain numerous fossil fishes, and these are the only fossils.

Lesquereux derives petroleum (Trans. Am. Phil. Soc. Philad., xiii. 313) mainly from the decomposition of fucoids and other marine plants, arguing for it on the ground of its occurrence so largely in rocks of marine origin. S. F. Peckham, in a recent communication to the author, sustains the idea that the light naphtha oils are solely of animal origin.

It is to be noted that wherever marsh or water plants have grown in past time there must have been also a profusion of minute animal life to afford nitrogen and sulphur to the accumulating debris; and, conversely, vegetable life of microscopic, if not also of larger kinds, is present wherever there is animal life.

The word naphtha is from the Persian *nafata*, signifying to *exude;* and petroleum from πέτρος, rock, and *oleum*, oil (the latter from the Greek ἔλαιον, *oil*), dating only from the middle ages (see SYN.).

Alt.—Petroleum undergoes alteration of condition in two ways:

1. *The evaporation of its lighter oils.* When exposed to the air the petroleum is free from pressure, except the ordinary atmospheric, and open to the heat and winds of the region. As a consequence the lighter naphtha oils pass off, leaving only the heavier, and the substance becomes gradually viscid, or even a solid consisting largely of solid hydrocarbons; and the so-called *asphalts*, which may thus result, will be ordinary bitumens of one kind or another, or largely paraffin, according as paraffin is present or not in the native oil.

In most oil regions, when the oil occurs at the surface open to the air, more or less of solid bitumen is to be found. Hunt speaks of the large "gum-beds" of half-dried bitumen in the oil region of Enniskillen; and Winchell says that in the neighboring but less productive district in Michigan, masses of inspissated oil are common, and some are as hard as asphalt. At the naphtha island of Tschelekan there are large quantities of *Nefl-gil*, as it is there called, which is nearly pure paraffin. The hot climate of the Caspian is favorable for such a result.

2. *The oxydation of some or all of the ingredients constituting the petroleum.* In the process of oxydation there is first a loss of some of the hydrogen by its union with oxygen to form water, which escapes. Thus the oils of the Marsh-gas series ($\Theta_n H_{2n+2}$) may pass to the less stable ethylenes ($\Theta_n H_{2n}$); or, by further loss of hydrogen, to species of the Benzole series ($\Theta_n H_{2n-6}$), or of the Naphthalin series ($\Theta_n H_{2n-12}$). The last two appear to occur sparingly in nature. *Secondly*, there is *oxygenation;* that is an absorption of, and union with, oxygen. These oxygenated substances have been yet but little investigated (see ASPHALTUM). They are probably all solid at the ordinary temperature.

Hard bitumen or asphalt may hence consist either (1) of unoxygenated, or (2) partly of unoxygenated and partly oxygenated, the usual fact; or (3) solely of oxygenated hydrocarbons (very rarely, if ever, true in nature). The state of solidity is not proof that any part of the bitumen is oxygenated.

SCHEERERITE GROUP.

Wax-like, or butter-like. General formula that of the Marsh-gas series, or $\Theta_n H_{2n+2}$. The two species here included are, according to the analyses (which need verification), polymeres of the first two species of the Marsh-gas series, ΘH_4, and $\Theta_2 H_6$.

The *Paraffins* belong here if members of the Marsh-gas series. See p. 730.

772. SCHEERERITE. Scheererit *Stromeyer*, Kastn. Arch., x. 113, 1827; Naphthaline résineuse prismatique *Könlein*, Bibl. Univ., xxxvi. 316, 1827; Macaire-Prinsep, Bibl. Univ., xl. 68, 1829, Ann. Phys. Ch., xv. 294.

Monoclinic. Crystals mostly thin tabular, rhomboidal or six-sided, often flattened parallel to *i-ì*, with also the planes *I*, –1, 1-*i*; edge *I*/*I* on –1/–1 =123½°, edge –1/–1 on 1-*i*=135°, edge *I*/*I* on 1-*i*=101½°, Kenngott. Also acicular. Also in loosely aggregated crystalline grains and folia.

Soft. G.=1—1·2. Lustre pearly or resinous; feebly shining. Color whitish, gray, yellow, green, pale reddish. More or less translucent to transparent. Easily frangible. Tasteless. Inodorous. Feel not greasy Soluble easily in alcohol, and also in ether. Melts at 44° C., and then resembles a fatty oil, and like it penetrates paper; these spots, however, may be removed by heat. On cooling, the mineral crystallizes in acicular crystals. May be distilled without decomposition; boiling point near 100° C. (92°, Prinsep).

Comp., etc.—According to an imperfect analysis by Prinsep (Pogg., xv. 294), consists of Carbon 73, hydrogen 24=97, which corresponds nearly to the ratio for Θ, $H=1:4$, or the composition of marsh-gas=Carbon 75, hydrogen 25=100; whence, if the results may be trusted, it is a polymere of marsh-gas.

Soluble in sulphuric or nitric acid, and not in alkalies. Takes fire easily and burns without residue, giving out much smoke and a feeble aromatic odor.

Found by Capt. Scheerer, in the year 1822, in the coal of a bed of brown coal in the Tertiary, at Uznach, near St. Gallen, in Switzerland. The bed of coal is two to three feet thick, and the pine stems in it are almost unchanged. Among the species of pine there is the *P. sylvestris*; and the birches and firs are those of modern species. The age is the same with that of the peat beds of Redwitz. Besides scheererite it affords also fichtelite and könlite. On cryst., Kenng., Ber. Ak. Wien, xiv. 272, and Min. der Schweiz, 418, Leipzig, 1866.

773. CHRISMATITE. Chrismatin (fr. Wattin) *Germar*, ZS. G., i. 40, 1849. Ozokerit (fr. ib.) *Breslau*, Karst. u. Dech. Arch., xxiii. 749, 1850. Hatchettin (fr. ib.) *Wagner*, Jahrb. Min 1864, 687; *H. Fleck*, Steinkohlen Deutschl., i. 37, 4to, München, 1865.

Butter-like, or of semifluid consistence. Soft at 55° to 60° C. G. below 1. Lustre greasy to silky. Color greenish to wax-yellow. Slightly translucent. Tasteless. Melts at a very low temperature to an oil, which is dark red by transmitted light, and apple-green by reflected.

Comp.—H. Fleck obtained (l. c.), 34 p. c. of ash being removed:

Carbon 78·512 Hydrogen 19·191 Oxygen 2·297=100.

Excluding the oxygen as water, as done by Fleck, it leaves C 80·51, H 19·49=100, corresponding to Θ_2H_6=Carbon 80, H 20; making it thus a polymere of Θ_2H_6, or the second member of the Marsh-gas series. Fleck adopts the formula $\Theta_{13}H_{28}$. If the oxygen is an essential constituent, either view of the constitution is wholly at fault. Burns with a flame, without smell.

Obs.—Occurs in cavities of calcite and quartz crystals in an argillaceous sandstone of the Carboniferous formation at Wettin, Saxony.

Named from χρῖσμα, *ointment*.

PITTOLIUM GROUP.

SYN. OF PITTASPHALT. Πιττασφάλτος *Dioscor.*, i. 100. Pissasphaltus *Plin.*, xxiv. 25, xxxv. 51 Maltha *Plin.*, ii. 108. Bergtheer *Germ.* Bitume visqueux, Bitume glutineux, Poix minerale Mineral graisse, *Fr.* Petroleum pt. Mineral Tar.

The species of this group are liquids like the naphtha oils, but are of higher specific gravity and atomic weight. They enter into the constitution of all free-flowing petroleum, but are especially characteristic of the denser kinds, and viscid bitumens, and exist largely also in many asphalts. They belong to the Ethylene series, and therefore have the general formula Θ_nH_{2n}=(alike for all) Carbon 85·71, hydrogen 14·29. G.=0·75—0·84.

The species ascertained to be native by C. M. Warren (Mem. Am. Ac.

Boston, ix., Am. J. Sci., II. xl.), and occurring in the Pennsylvania petroleum, Rangoon tar, etc., and the boiling temperatures, as ascertained by Warren, are the following:

	Formula.	Boiling T.
774. DECATYLENE (Rutylene)	$\Theta_{10}H_{20}$	174·9°
775. ENDECATYLENE (Margarylene)	$\Theta_{11}H_{22}$	195·8
776. DODECATYLENE (Laurylene)	$\Theta_{12}H_{24}$	216·2
777. DECATRITYLENE (Cocinylene)	$\Theta_{13}H_{26}$	235

The average increase in the boiling point for the successive members in the series (or the addition of ΘH_2), as follows from Warren's results, is 20°·6, or only *two-thirds* of the average in the Naphtha group. Other higher *native* species of the above series have not yet been clearly defined.

These compounds are made members of the Marsh-gas or Naphtha series by Pelouze and Cahours, who write the formulas as follows, and give the annexed specific gravities, vapor densities, and boiling points:

	G.	Vapor Density.	Boiling Temp.
$\Theta_{10}H_{22}$	0·757	5·040	160°—162°
$\Theta_{11}H_{24}$	0·766	5·458	180 —184
$\Theta_{12}H_{26}$	0·776	5·972	196 —200
$\Theta_{13}H_{28}$	0·792	6·569	216 —218

They also add the compounds $\Theta_{14}H_{30}$, $\Theta_{16}H_{32}$. Warren, by his superior methods, proves that the species obtained by them were not pure (l. c.).

Each of the four ethylene compounds above mentioned have been obtained from Rangoon tar, besides some species of the Naphtha group (at least Θ_7H_{16} and Θ_8H_{18}), traces of some of the Benzole series, and also naphthalin.

The name *pittolium* is from πιττα, *pitch*, and *oleum*, oil, analogous to *petroleum*; and *pittasphaltum*, from the Greek for *pitch* and *asphalt*.

The word *maltha* is from the Greek μαλθη, *soft wax*; it was also used sometimes for a mixture of wax and pitch, employed for making the surface of writing-tablets, and for some kinds of cements. But Pliny (ii. 108) describes under this name an inflammable mud flowing from a pool at Samosata in North Syria on the Euphrates, which he says (ii. 109) was similar in nature to naphtha; and this use of the word has led to its later application to viscid bitumens.

Petroleum in cavities in crystals. Davy, in his examinations of the fluids in crystals (Phil. Trans., 1822, 367, and postscript), found only water, except in the case of quartz from Dauphiny. The liquid in this case was about as viscid as linseed oil; brownish in color; became solid and opaque at 13° C. (56° F.); had a smell resembling naphtha; acted like a fixed oil when heated, the temperature of ebullition being high; and burned with flame, producing a white smoke. The cavity was ½ in. across, but only a sixth of it was occupied by the fluid. Davy made his investigations of the fluids in crystals by having the crystals bored through to the cavity by a lapidary, and was the first to use this method.

PETROLENE. Boussingault obtained from the viscid bitumen and asphalt of Bechelbronn an oil which he called *Petrolene*, and announced it as the *liquid* ingredient of all asphalt, the *solid* one being named by him *Asphaltene* (see ASPHALTUM). It was separated by heating in an oil bath to a temperature of 300° C. None of it passed over at a temperature below 100° C. He obtained for its composition (Ann. Ch. Phys., lxi. 141, lxxiii. 442):

Carbon	87·36	86·78	87·45	86·98	(?) 88·4.
Hydrogen	11·90	12·20	12·30	12·70	12·5.

He writes for it the formula $\Theta_{10}H_{16}$, making it of the camphene series, Θ_nH_{2n-4}. It boiled at 280° C. The vapor density is stated at 9·415, or "double that of oil of turpentine."

There can be no doubt that the petrolene was a mixture of oils. Warren states (priv. contrib.) that from Boussingault's data, as given in his article, the vapor density should have been 8·49 instead of 9·415; and also that his own researches on various hydrocarbon oils, including the products from the destructive distillation of albertite, lead him to believe that petrolene probably consists mainly of oils of the *Ethylene* series; that $\Theta_{16} H_{32}$ would have for its boiling point 295° C. and vapor density 7·745; but that the liquid is made up of oils of both less and greater density.

The Bechelbronn tar and that similar from Lobsann (both in the Dept. of Bas-Rhin, France) are called also *Mineral Graisse* and *Graisse de Strasbourg*.

Völckel has subjected a viscid bitumen from Travers, near Neufchatel, to distillation in iron cylinders (Ann. Ch. Pharm., lxxxvii. 143, 1862), and obtained the following as his successive results:

	C	H	Temp. of vaporization.	G.
1.	87·56	12·34= 99·90	90°—120° ¹	0·784 at 15° C.
2.	87·59	12·30= 99·89	120 —150	0·790
3.	87·31	12·59= 99·99	150 —180	0·802
4.	87·34	12·69=100·03	180 —200	0·817
5.	87·48	12·60=100·08	200 —220	0·845
6.	87·40	12·40= 99·80	220 —250	0·867

The analyses afford for all of the compounds the ratio for Θ, H, 6 : 10, and Völckel regards them as polymeres of $\Theta_{12} H_{20}$, and hence of the camphene series and similar to petrolene But (as Warren observes) with such a mode of distillation *artificial* products were likely to have been obtained, and among them benzole or naphthalin; and the presence of either of these compounds would account for the divergence from the ethylene series.

The composition is compared by Völckel to that of *oil of amber* (an admitted product of distillation, and not native to amber). Döpping obtained for the oil of amber passing over at 200° C., C 87·48, 87·32, H 12·06, 11·98=99·54, 99·30. The ratio for Θ, H, is 5 : 8, which is also that for amber itself; and the formula is $\Theta_{10} H_{16}$, or that arrived at by Boussingault for his petrolene.

Solid Petrolene. The asphalt of Peklenicza (Muraköz), Austria, affords a *solid* portion, soluble in ether and hardly at all so in alcohol (in this respect like the asphaltene of Boussingault), which, according to Nendtvich (Haid. Ber., iii. 271, Jahrb. G. Reichs., vii. 743), has the *same composition with petrolene.*

The observations thus far made *seem* to point to a Camphene series of Hydrocarbons as characteristic of many viscid bitumens, and of some, if not many, asphalts. But the investigations have not been sufficiently exact to sustain satisfactorily the conclusion.

PARAFFIN GROUP.

Wax-like in consistence; white and translucent. Sparingly soluble in alcohol, rather easily in ether, and crystallizing more or less perfectly from the solutions. G. about 0·85—0·98. Melting point for the following species, 33°—90°.

General formula $\Theta_n H_{2n}$, or that of the ethylene series, according to many authors,=Carbon 85·71, hydrogen 24·29=100; $\Theta_n H_{2n+2}$, according to others. The peculiar inertness of the paraffins with regard to chemical combination is urged by Watts and Frankland as favoring the latter formula. Whichever the series, they are regarded as species of high atomic weight, *n* not being less than 28. The different species, varying in the value of *n*, vary also in boiling point, and other characters. Those here recognized have not been studied with that care which is demanded for full confidence in their stated composition, or in their purity as simple species.

Paraffins occur in the Pennsylvania petroleum, a freezing mixture reducing the temperature being sufficient to separate it in crystals. Also in the naphtha of the Caspian, in Rangoon tar, and many other liquid bitumens. It is a result of the destructive distillation of peat, bituminous coal, lignite, coaly or bituminous shales, most viscid bitumens, wood-tar (from which it was first obtained by Reichenbach), and many other substances

The name is from the Latin *parum*, *little*, and *affinis*, alluding to the feeble affinity for other substances, or, in other words, its chemical indifference.

778. URPETHITE. Part of Ozocerite (fr. Urpeth Colliery) *J. F. W. Johnston*, Phil. Mag., III. xii. 389, 1838. Urpethite *Dana*.

Consistence of soft tallow. G.=0·885, Johnston. Color yellowish-brown to brown. Adheres to the fingers, and stains paper. Melting point 39° C. Soluble readily in cold ether.

Comp.—Analysis: Johnston (l. c.):

Carbon 85·83 Hydrogen 14·17=100.

Ethereal solution brown by transmitted light, but with a greenish opalescence by reflected, deposits the wax in brown flocks. Melts at 39° C. to a yellow-brown liquid.

Obs.—Constitutes about *four-fifths* of the Urpeth Colliery ozocerite, and is separated from the latter through its solubility in *cold* ether. The crude wax, as found, was soft enough to be kneaded in the fingers; had a greasy feel, and gave a greasy stain to paper; was subtransparent; of a brownish-yellow color by transmitted light, but yellowish-green and opalescent by reflected; and had an odor slightly fatty, which was stronger when melted. It occurred in cavities near a fault in the coal measures, and part in the solid sandstone.

Laurent obtained a variety of paraffin by the dry distillation of the bituminous shale of Autun, which *melted at* 33° C., was very soluble in ether and insoluble in alcohol, and which consisted of Carbon 85·745, hydrogen 14·200=99·945. It may be identical with the above. It is quite probable that the urpethite obtained by Johnston was not free from mixture with the second paraffin separated by him from the Urpeth mineral by means of boiling ether, which is here referred to ozocerite (p. 732); and such a mixture might account for the divergence of the melting point from that of Laurent's paraffin. Taking 33° C. as the true melting point, the several paraffins here described, urpethite, hatchettite, ozocerite, Johnston's *third* from the Urpeth wax, and zietrisikite, have nearly a common difference in melting points of 13°—17°, the temperatures being respectively 33°, 46°, 60°, 73° 90°. The mean difference is about 14°; this would make the melting points 33°, 47°, 61°, 75°, 89°.

779. HATCHETTITE. Hatchetine (fr. Merthyr-Tydvil) *Conybeare*, Ann. Phil., i. 136, 1822. Mineral Adipocire, Mountain Tallow (fr. Loch Fyne), *Brande*, Ed. Phil. J., xi. 1824. Hatchetine (fr. Glamorganshire) *J. F. W. Johnston*, Phil. Mag., III. xii. 338.

In thin plates, or massive. Reported as sometimes occurring as large crystals in fresh specimens.

H. like that of soft wax. G.=0·916, Johnston; 0·983, fr. Loch Fyne, after melting and excluding air bubbles, Brande; 0·608, same before melting, id. Lustre slightly glistening and pearly. Color yellowish-white, wax-yellow, greenish-yellow; blackens on exposure. Subtransparent to translucent; but opaque on exposure. Feel greasy. Without odor. Melting point 46° C., fr. Merthyr-Tydvil, Johnston; 47° C., fr. Loch Fyne, Brande. Polarizes light in patches, Brewster.

Comp., etc.—Ratio of C, H=nearly 1 : 1, from Johnston's analysis,=Carbon 85·55, hydrogen 14·45=100. Analysis: Johnston (l. c.):

Glamorganshire Carbon 85·91 Hydrogen 14·62=100·58.

Very sparingly soluble in boiling alcohol, and precipitated from the solution on cooling. Also soluble sparingly in cold ether, and more largely in boiling; and from the latter deposited in a mass of minute fibres or prisms. After repeated boiling with ether there remains only a minute portion undissolved, mixed with particles of charcoal derived from the blackened surface of the specimen. Charred and decomposed by concentrated and boiling sulphuric acid. No apparent change in boiling nitric acid. Conybeare (l. c., 1822) stated that the Merthyr-Tydvil hatchettite "melts in warm water under 170° F., whereas true bitumen does not in boiling water;" and this loose remark is the only ground for the statement that 76·6° C. is the melting point of one variety of the mineral.

Obs.—From the crevices of iron-stone septaria, and often in geodes containing also quartz crystals, in the coal-measures near Merthyr-Tydvil in Glamorganshire (and, Johnston adds, in some of the midland counties of England); also in a bog on the borders of Loch Fyne in Argyleshire, Scotland. The latter has not yet been analyzed. Also reported from Rossitz in Moravia (Jahrb. G. Reichs., 1854, 898), in the Segen Gottes mine, with spherosiderite, as a thin coating on calcite, having H.=1, G.=0·892, Patera.

This species (or at least the bog variety from Loch Fyne) is probably identical with the kind of paraffin that fuses at 45°—47° C.; and which has been obtained by the destructive distillation of Boghead coal and peat, and from other sources. Anderson obtained in his analyses of this paraffin:

	C	H	Melting T.
1. From Boghead coal, *cryst.*	85·1	15·1—15·3	45·5°
2. " " " *granular*	85·0—85·3	15·4	52
3. From peat	(½) 85·09	15·10	46·7

The Boghead coal (from Boghead and Torbane Hill, near Bathgate in Linlithgowshire) affords on destructive distillation a very large amount of different oils and paraffin, 70 p. c. of the dried mass being volatile. See Bathvillite beyond (p. 742).

Named after C. Hatchett.

730. OZOCERITE. Part of Native Paraffin. Ozokerit (brought by v. Meyer fr. Slanik, Moldavia) *Glocker*, Schw. J., lxix. 215, 1833; *Magnus*, Ann. Ch. Phys., lv. 217, 1834. Cire fossile *Fr.* Erdwachs *Germ.*

Like wax or spermaceti in appearance and consistency.

G.=0·85—0·90. Colorless to white when pure; often leek-green, yellowish, brownish-yellow, brown; and when brown sometimes greenish by transmitted light. Often having a greenish opalescence. Translucent. Greasy to the touch. Fusing point 56° to 63° C.

Comp., etc.—The original ozocerite, from Slanik in Moldavia, as described by Glocker (l. c. and Arsb., 1834, 208), was wholly soluble in ether, and gave a yellow solution; also soluble in oil of turpentine and naphtha; and a little soluble in boiling alcohol. G. of the mass 0·955, Glocker; 0·953, Schrötter. Melting point 62° C., Schrötter.

The mineral wax of Urpeth Colliery, after the separation of what was soluble in cold ether (see Urpethite, p. 731), afforded Johnston (l. c.) another portion through its solubility in boiling ether; and this is apparently identical with true ozocerite. While soluble in boiling ether it is sparingly so in boiling alcohol. As obtained from the ether solution it was yellow, and had the consistence of soft wax.

A kind from Boryslaw in Galicia, examined by Hofstädter (Ann. Ch. Pharm., xci. 326, 1854), resembled the preceding in its appearance, but was darker colored, being blackish-brown; in thin pieces reddish-brown to leek-green by transmitted light; G.=0·944; melting point 60°. By fractional crystallization it was separated into parts varying in fusibility from 60° to 65° 5' C. That from Truscawitz, Galicia, examined by Walter (J. pr. Ch., xxii. 181) appears to be similar.

Analyses: 1, Schrötter (Baumg. ZS., iv. 2, 1836, Bibl. Univ. de Genève, iii. 184, 1836); 2, Johnston (l. c.); 3, Walter (l. c.); 4, 5, Hofstädter (l. c.):

	C	H	Melting T.	Boiling T.	G.	
1. Slanik	84·43	13·69=98·12	62°—63° C.	210°	0·953	Schrötter.
2. Turpeth C.	86·80	14·06=100·86	58	?		Johnston.
3. Truscawitz, *crude*	84·62	14·29=98·91	59	ov. 300		Walter.
4. Boryslaw, A.	84·94	14·87=99·81	61		0·944	Hofstädter.
5. " B.	85·78	14·29=100·07	65·5			Hofstädter.

The A of Hofstädter was the portion separated by fractional crystallization which had 61° C. as the melting point, and the B that which had for this point 65·5°.

The above results agree closely, and probably the ozocerite in the specimens examined was but little impure from mixture with other paraffins.

Hermann has described a wax-like mixture from seams in a rock in the vicinity of Lake Baikal; which he calls *Baikerite* (J. pr. Ch., lxxiii. 230). About 60·18 p. c. of it was soluble in boiling alcohol, 100 parts dissolving 1; and this portion appears to be ozocerite. It was tasteless and inodorous; melting point 59° C.; G.=0·90. The rest (29·82 p. c.) of the baikerite consisted as follows: 7·02 wax-like substance insoluble in alcohol; 32·41 viscid resin; 0·39 earthy impurities.

The same compound has been obtained from mineral coal, peat, and petroleum, mineral tar, etc., by destructive distillation. The following are examples: 1, Anderson (Rep. Brit. Assoc., 1856, J. pr. Ch., lxxii. 379); 2, Hofstädter (l. c.):

	C	H	Melting Point.	
1. Rangoon Tar	85·15	15·29=100·44	61°	Anderson.
2. From Bitum. shale, Bonn.	86·16	14·36=100·52	61°	Hofstädter.

Ozocerite occurs at each of the localities mentioned, in beds of coal, or associated bituminous deposits; that of Slanik, Moldavia, beneath a bed of bituminous clay shale; in masses of sometimes 80 to 100 lbs., at the foot of the Carpathians, not far from beds of coal and salt: that of Boryslaw in a bituminous clay associated with calciferous beds in the formation of the Carpathians, in masses. Reported also from near Gaming in Austria; in Transylvania, near Moldavia, in the Carpathian sandstone; at Uphall in Linlithgowshire.

Named from ὄζω, *I smell*, and κηρός, *wax*, in allusion to the odor.

781. ZIETRISIKITE. Cire fossile de Moldavie *Magnus*, Ann. Ch. Phys., lv. 217, 1833. Ozockerite (fr. Zietrisika) *Malaguti*, C. R., iv. 410, 1837, Ann. Ch. Phys., lxiii. 390, Pogg., xliii. 147. Zietrisikite *Dana*.

Like ozocerite in nearly all physical characters.

Hardness like that of beeswax, or harder. G.=0·9; 0·946, Malaguti. Color brown. Melting point 90° C.; 82°—84° in the crude or impure mineral. Insoluble in ether.

Comp., Var., etc.—The almost complete insolubility of this fossil wax in ether distinguishes it decisively from ozocerite.

1. Magnus, who made the first examination of the fossil wax brought by v. Meyer from Slanik. Moldavia, appears to have had a different substance in hand from that examined by Glocker (by whom *ozocerite* was named) and by Schrötter, as he states that only a very little of it was dissolved by alcohol or ether, and the rest, after the action of these solvents, was eroded with holes, showing the presence of insoluble and soluble constituents. The insoluble was soluble in oil of turpentine, and of this part the melting point was 82°, and the composition as given below.

2. The wax from Zietrisika, Moldavia, examined by Malaguti, is regarded by him as identical with that of Magnus. It was foliated, conchoidal in fracture, pearly in lustre, deep red-brown in color with a greenish reflection, but in very thin pieces brown, and a little harder than beeswax. It was very slightly soluble in alcohol or boiling ether, and very soluble in oil of turpentine and naphtha, with no action from alkalies or cold sulphuric acid. It melts at 84° C., and boils at above 300°. On subjecting it to boiling alcohol, a small portion was dissolved, whose melting point was 75°; by a second treatment another portion was obtained, having for the melting point 78°; and at the fourth, the portion dissolved was found to have the same melting point as that of the undissolved mass, which was 90°. This then, which he calls *brown* ozocerite, appears to be the point of fusion of the true zietrisikite, and this alone was analyzed; as the rest, his *yellow* ozocerite, he says, "est un mélange, j'ai jugé inutile d'en faire l'analyse."

Analyses: 1, Magnus (l. c.); 2, 3, Malaguti (l. c.):

	C	H	Melting T.	Boiling T.	
1. Moldavia	84·61	15·30=99·91	82° C.		Magnus.
2. Zietrisika, Mold.	84·58	14·22=98·75	90	Above 300° C.	Malaguti.
3. " "	84·78	14·37=99·15	90	"	Malaguti.

The wax from Zietrisika, in Moldavia, occurs in large masses, and under similar circumstances with that of Slanik.

781A. Johnston, in his examination of the Urpeth Colliery wax (see URPETHITE and OZOCERITE), after separating by ether (first cold, and then boiling) about five-sixths of the mass, obtained for the remaining sixth a *third* portion, almost insoluble in ether, having G.=0·955; color dark brown consistence like that of wax; melting point 73° C., and boiling point above 260° C. It may be identical with the above, but its melting point would imply that it was distinct. He obtained for its composition C 83·81, H 13·65=97·46.

781B. Neft-gil (Naphtdachil, Nephatil, Jahrb. Min. 1846, 84. Naphthadil *Kenng.*, Ueb. 1844–'49, 254. Neftdegil *Herm.*, J. pr. Ch., lxxiii. 220. Neft-gil *Fritzsche*, ib., 321). A very abundant material in the naphtha region on Tscheleken I., in the Caspian. It is a mixture of paraffins and a resin, but appears to be most nearly related to zietrisikite. G.=0·956; color chocolate-brown; melting point 75° C. Hermann found 66 p. c. of a wax-like substance insoluble in alcohol, and 18 p. c. of another soluble in alcohol, besides 13·33 p. c. of a resin. In ether a large part was insoluble; and this portion may be identical with the zietrisikite, or the insoluble paraffin from the Urpeth wax (p. 731).

781C. Pyropissite *Kenng.*, Ueb. 1850–'51, 148. Kenngott has thus named an earthy, friable, coaly substance, of grayish-brown color, and without lustre, and having G.=0·493—0·522, which forms a layer 6 to 9 in. thick in brown coal at Weissenfels, near Halle. It is a mixture of species instead of a mineral, and has not yet been properly investigated. A small part is soluble in alcohol, especially in boiling, and this, precipitated by adding water, is a wax-like substance, paraffin-like in aspect. But whether true paraffin, or whether an oxygenated wax, related to geocerite (a species derived from a similar earthy brown coal from Gersterwitz, near Weissenfels), has not been ascertained. It melts easily to a pitch-like mass, and hence the name, from πῦρ, *fire*, and πίσσα, *pitch*. It affords 62 p. c. of paraffin on dry distillation. On the composition of the related Gersterwitz earthy coal, see pp. 757, 758; also, *C. Karsten*, ZS. G., ii. 71. And for other papers on a similar material from Helbra, between Mansfeld and Eisleben, see *Voigt*, Brennbarer Fossil fr. Helbra, Vers. Gesch. Steinkohle, etc., 188, 1802, J. d. M., xv. 77, 1804; G. Heine, id., Jahrb. Min. 1845, 149. Such coals are sometimes called *Paraffin coal*, and in German *Wachskohle*. Kenngott refers here also an earthy brown substance from Mettenheim, which melts similarly to an asphalt-like substance; no other evidence of identity is stated. It occurs incrusting massive limestone.

782. ELATERITE. Subterranean Fungus (fr. Derbyshire) *Lister*, Phil. Trans., 1673. Elastic Bitumen. Mineral Caoutchouc. Bitume élastique *Delaméth.*, J. de Phys., xxxi. 31, 1787. Elastic Bitumen *Hatchett*, Linn. Trans., iv. 146, 1797. Elastiches Erdpech *Klapr.*, Beitr., iii. 107, 1802. Elastisches Erdharz *Germ.* Elaterit, Fossiles Erdharz, *Hausm.*, Handb., i. 87, 1813.

Massive, amorphous.

G.=0·905—1·233, fr. Derbyshire. Soft, elastic, sometimes adhering to the fingers (*a*); also moderately soft and elastic; much like india-rubber (*b*); and occasionally hard and brittle (*c*), imbedded in the softer kinds. Color brown, usually dark brown. Subtranslucent; sometimes dark orange-red by transmitted light.

Comp., etc.—Johnston analyzed the three kinds, *a*, *b*, *c*, separately. He mentions the action of ether only on the *b*, from which it separated but 18 p. c. of the mass; and the two analyses given are those of the undissolved material. Analyses:

	C	H
1 (*a*)	85·474	13·283=98·757.
2 (*b*)	84·385	12·576=96·961.
3 (*b*)	83·671	12·535=96·206.
4 (*c*)	85·958	12·342=98·300.
5 (*c*)	86·177	12·423=98·600.

He states that the loss in *a* and *c* may be partly or wholly oxygen, and that in the case of *c*, o the insoluble residue, 3—3·8 p. c. is oxygen. He thus leaves the constitution of elaterite in doubt. It appears to be partly a carbohydrogen near ozocerite, and partly an oxygenated insoluble material. Mr. Henry, Jr., found 36 to 40 p. c. of oxygen (J. de Ch. Médicale, i. 18); but his results, as Johnston observes, are evidently untrustworthy.

It is found at Castleton in Derbyshire, in the lead mine of Odin, along with lead ore and calcite, in compact reniform or fungoid masses, and is abundant. Also reported from St. Bernard's Well, near Edinburgh; Chapel quarries in Fifeshire; a coal mine at Montrelais, at the depth of 230 feet; and, according to Hausmann (Handbuch, iii. 273), at Neufchatel, and on the island of Zante. A similar material in external characters has been met with at Woodbury, Ct.

783. **Settling Stones Resin** (New Mineral Resin (fr. Settling Stones) *J. F. W. Johnston*, Edinb. J. Sci. II. iv. 122, 1831, Phil. Mag., III. xiv. 88, 1839. Elaterite?) In the form of drops, more or less rounded, or flattened, as if once fluid or soft, and found incrusting the rocky walls of a vein at an old lead mine in Northumberland, known by the name of Settling Stones, resting on and occasionally covered by calcite and pearl spar; the rock is the Mountain limestone (Subcarboniferous). It is hard, brittle under the hammer, but difficult to reduce to powder; G =1·16—1·54; color from pale yellow to deep red; a pale green opalescence; *does not melt at* 205° C. Burns in the flame of a candle. Very slightly acted upon by alcohol.

Comp., etc.—O. ratio for Θ, H=nearly 2 : 3 (?); an analysis affording Johnston (l. c.):

Carbon 85·133 Hydrogen 10·853 Ash 3·256=99·242.

But Johnston adds: "It is therefore *doubtful whether this resinoid substance contains oxygen or not*. It may be only an impure carbo-hydrogen." It is very slightly acted upon by alcohol. Gives empyreumatic products when fused in a closed tube. It has close relations to elaterite.

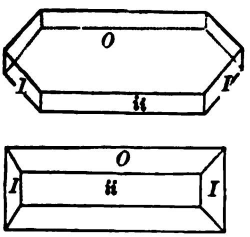
FICHTELITE GROUP.

The Fichtelite group, according to the analyses, belongs to the Camphene series of hydrocarbons, the general formula for which is $\Theta_n H_{2n-4}$.

Petrolene, or more correctly the petrolene group of oils, has been referred to the Camphene series; and should constitute a group preceding the Fichtelite group, if the analyses were made on pure species, and are to be credited. See p. 729.

784. **FICHTELITE.** Tekoretin *Forchh.*, Vid. Selsk. Afh. Copenh., 1840, J. pr. Ch., 459, 1840 Fichtelit *Bromeis*, Ann. Ch. Pharm., xxxvii. 304, 1841; *T. E. Clark*, Ann. Ch. Pharm., ciii. 236, 1857, Am. J. Sci., II. xxv. 164.

616



Monoclinic. $C=53°$, $I \wedge I=83°$ and 97°; $I \wedge i\text{-}i=131° 30'$, $O \wedge i\text{-}i=127°$, $O \wedge 1\text{-}i=105°$, $i\text{-}i \wedge 1\text{-}i=128°$, Clark. Crystals lengthened in the direction of the orthodiagonal.

H.=1. Lustre somewhat greasy. Color white. Translucent. Brittle. Without taste or smell. Distils over without decomposition. Solidifying temperature 36° C. Easily soluble in ether; less so in alcohol.

Comp., Var., etc.—Ratio of Θ, H=5 : 8=Carbon 88·35, hydrogen 11·65. Analyses: 1, Bromeis (l. c.); 2, Clark (l. c.); 3, Forchhammer (l. c.):

		C	H	Melting T.	Boiling T.	
1. Redwitz		87·95	10·70=98·65	46°		Bromeis.
2. "	(⅓)	87·13	12·86=99·99	46	above 320°	Clark.
3. *Tecoretin*		85·89	12·81=98·70	45	360	Forchh.

Decomposed by anhydrous sulphuric acid; also by heated fuming nitric acid; soluble in cold nitric.

Clark, after a revision of the investigations on fichtelite and the related resins, concludes that there is no doubt of the identity of the substance analyzed by him with Bromeis's *fichtelite*, and deduces the empirical formula $\Theta^5 H^8$.

The mineral occurs in the form of shining scales, flat crystals, and thin layers between the rings of growth and throughout the texture of pine wood (identical in species with the modern *Pinus sylvestris*) from peat beds in the vicinity of Redwitz, in the Fichtelgebirge, North Bavaria The crystals described by Clark (f. 616) were obtained artificially by means of ether and alcohol.

An *oily* substance was extracted by Schrötter by means of ether from wood of the same peat bed which afforded the fichtelite; and this solution yielded two substances, one of which was an oil, regarded by him as identical with fichtelite in ratio; it gave on analysis, Carbon 88·58, hydrogen 11·34=99·42. The other substance was crystallized and contained oxygen.

Tecoretin was obtained from pine trees of the same species in marshes near Holtegard in Denmark. The resin from the wood, first observed by Steenstrup, was found by Forchhammer, after dissolving it in boiling alcohol, to contain two substances crystallizing from the solution at different temperatures. The *tecoretin* was the least soluble of the two, or that which crystallized out first (the other was his *phylloretin*, see p. 737); its crystallization was *monoclinic*, and its fusing point 45°. From the analysis Clark writes the empirical formula $\mathrm{Ɵ}\,\mathrm{H}^2$; but states that the mineral resembles fichtelite in every other respect.

785. HARTITE. Hartit *Haid.*, Pogg., liv. 261, 1841. Branchite *Savi*, Cimento, i. 342, Jahrb Min. 1842, 459.

Monoclinic. Resembling fichtelite in crystalline form, lustre, color, translucency, and the reactions with alcohol, ether, and the acids. But melts at 74°–75° C. Boiling temperature very high.

Comp., etc.—Ratio of Ɵ, H=12 : 20=Carbon 87·8, hydrogen 12·2. Analyses: 1, Schrötter (Pogg., lix. 37); 2, Piria (Cimento, i. 346, Jahresb. 1855, 984):

	C	H
1. *Hartite*	87·47	12·04=99·51 Schrötter.
2. *Branchite*	87·0	13·4=100·4 Piria.

Piria's analysis corresponds nearly with the ratio 9 : 16.

Obs.—*Hartite* is found in a kind of pine, like fichtelite, but of a different species, the *Peuce acerosa* Unger, belonging to an earlier geological epoch. It is from the brown coal beds of Oberhart, near Gloggnitz, not far from Vienna. Reported also from Rosenthal near Köflach in Styria, and Prävali in Carinthia. It occurs among the layers or tissues of the wood, and also in clefts in the coal or lignite.

Branchite is colorless and translucent, with G.=1·0442, and comes from the brown coal of Mt. Vaso in Tuscany. It is soluble in alcohol, like hartite.

786. DINITE *Meneghini* (Gaz. Med. Italiana, Firenze, Toscana, July, 1852). Occurs as an aggregation or druse of crystals; cleavage none; with the appearance of ice, but with a yellow tinge due to a foreign substance. Inodorous; tasteless; fragile, and easily reduced to powder. Insoluble in water; little soluble in alcohol, very soluble in ether and in sulphuret of carbon. The ethereal solution on standing deposits large crystals of the dinite. Fuses with the warmth of the hand; heated in a close vessel distils over without undergoing any sensible decomposition When melted it looks like a yellowish oil; crystallizes in large transparent crystals on cooling.

From a lignite deposit at Lunigiana, Tuscany, where it was found by Prof. Dini.

787. IXOLYTE (Ixolyt *Haid.*, Pogg., lvi. 345, 1842). Amorphous. H.=1. G.=1·008. Lustre greasy. Color hyacinth-red. Pulverized in the fingers, it becomes ochre-yellow and yellowish-brown. Thin fragments subtranslucent. Fracture imperfect conchoidal in the purer varieties.

Softens at 76° C., but is still tenacious at 100° C., whence the name, from ἰξός, *gluey, like birdlime*, and λύω, *to dissolve*.

This species is said to resemble hartite, though differing in the temperature of fusion and other characters It occurs in a coal bed at Oberhart, near Gloggnitz; pieces sometimes half an inch thick, associated with hartite.

BENZOLE GROUP.

Oily fluids at the ordinary temperature. General formula $\Theta_n H_{2n-6}$. Soluble in alcohol and ether. The species observed in nature, which include all those known of the Benzole series, are the following:

		C	H	G.	Boiling T.
788. Benzole	$\Theta_6 H_6$	=92·31	7·69=100	0·85 at 15·5° C.	82° C.
789. Toluole	$\Theta_7 H_8$	=91·30	8·70=100	0·88 at 5	111
790. Xylole	$\Theta_8 H_{10}$	=90·57	9·43=100	0·86 at 19	139
791. Cumole	$\Theta_9 H_{12}$	=90·00	10·00=100	0·87	148
792. Cymole	$\Theta_{10} H_{14}$	=89·55	10·45=100	0·86 at 14	175

W. de la Rue and H. Müller detected in 1856, in Rangoon tar, the first three of the above species, with another designated pseudocumole (isocumole). In 1860 Bussenius and Eisenstuck (Ann. Ch. Pharm., cxiii. 151) announced xylole as present in the petroleum of Sehnde in Hanover; and the same year (ib., cxv. 19) Pebal and Freund detected all the above five species of the series in the naphtha of Boroslaw in Galicia. Warren and Storer also (Mem. Am. Ac. Boston, ix. 216) have detected xylole and "isocumole" in the Rangoon tar. None of the series were detected by Pelouze and Cahours in the Pennsylvania petroleum.

These oils are produced in the destructive distillation, at high temperatures, of bituminous coals, fatty substances, etc.

793. KÖNLITE. (Fr. Uznach) *Kraus*, Pogg., xliii. 141, 1838. Könlit (fr. ib.) *Schrötter*, ib., lix. 37, 1843; (fr. Redwitz) v. Trommsdorff, Ann. d. Pharm., xxi. 126. Könleinit *Hausm.*, Handb., 1487, 1847; *Kenngott*, Ber. Ak. Wien, xiv. 272, Min. d. Schweiz, 419, Leipzig, 1866.

In folia and grains; amorphous; stalactitic.

Soft. G.=0·88, Trommsdorff. Color reddish-brown to yellow. Melting point 114° C., Kraus; 107½°, Trommsdorff. Distils at 200°, undergoing decomposition at the same time, and leaving a brown residue. Very slightly soluble in cold and hot alcohol; much more soluble in ether; the latter solution affording wax-like folia.

Comp.—Ratio of Θ, H=1 : 1; n$(\Theta_6 H_6)$ or a polymere of benzole. Fritzsche makes the formula $\Theta_{18} H_{18}=3(\Theta_6 H_6)$. (Bull. Ac. St. Pet., iii. 88, 1860.) Analyses: 1, Kraus (l. c.); 2, v. Trommsdorff (l. c.):

	C	H
1. Uznach, Switz.	92·429	7·571=100 Kraus.
2. Redwitz, Bavaria	90·90	7·58=98·48 Trommsdorff.

The Redwitz mineral may be a different species. Könlite, unlike scheererite, is changed by distillation, yielding a substance which melts by the *warmth* of the hand. For this product Krauss proposed the name *pyroscheererite*.

In brown coal at Uznach, at the same locality with scheererite; near Redwitz, Bavaria, in the Fichtelgebirge, with fichtelite; reported by Kenngott from the brown coal of Fossa in the Eger valley (Ueb., 1850–'51, 147).

Named after Könlein, formerly superintendent of the coal works at Uznach.

Phylloretin of Forchhammer (J. pr. Ch., xx. 459, 1840) is near the above, and is made identical with it by Fritzsche. It was obtained from an alcoholic solution of a resin from the marshes near Holtegard in Denmark; the more soluble of the two resins obtained (see p. 736) being the *phylloretin*. Fusing point 86°–87°. Dissolves easily in alcohol. Forchhammer obtained Carbon 90·22, 90·12, hydrogen 9·22, 9·26; and deduces for the ratio of Θ, H, 8 : 10

794. NAPHTHALIN.

Orthorhombic. Commonly, as artificially prepared, in rhombic tables of 122° and 78° with the acute angles truncated, or hexagonal tables.

Lustre brilliant. Color white. G.=1·153 at 18° C.; 0·9778, at 79·2° C., Kopp.; at which temperature it melts. Boiling point 218° C. Dissolves readily in alcohol, ether, oil of turpentine, fatty oils, etc.

Comp., etc.—$\Theta_{10} H_8$=Carbon 93·75, hydrogen 6·25=100. The first of the *Naphthalin* series, the general formula for which is $\Theta_n H_{2n-12}$. Burns with a dense smoking flame.

Obs.—Found sparingly in Rangoon tar, by De la Rue and Müller, and by Warren and Storer.

Artif.—Formed easily from petroleum, coal-naphtha, essential oils, on passing them through red-hot tubes.

795. IDRIALITE. Quecksilberbranderz pt. Idrialine (fr. Idria) *Dumas*, Ann. Ch. Phys., l. 360, 1832. Idrialite *Schrötter*, Baumg. ZS., iii. 245, iv. 5.

In the pure state crystalline in structure. Color white. In nature found only impure, being mixed with cinnabar, clay, and some pyrite and gypsum in a brownish-black earthy material, called, from its combustibility and the presence of mercury, *inflammable cinnabar* (*Quecksilberbranderz*).

Comp., etc.—Dumas separated the idrialite by treatment with oil of turpentine. Analyses: 1, Dumas (l. c.); 2, 3, Schrötter (l. c.):

Carbon	94·9	94·50	94·80
Hydrogen	5·1 D.	5·19 Schr.	5·49 Schr.

Corresponding to the ratio for Θ, H about 3 : 2=Carbon 94·74, hydrogen 5·26=100. Insoluble in water, and little so in alcohol or ether. Fuses at 205° C. Schrötter found in one specimen of the crude mineral 77·32 idrialite, 17·85 cinnabar, and 2·75 of other impurities.

Bödecker (Ann. Ch. Pharm., lii. 100, 1844) obtained for the composition of a substance he derived from the crude material, $(\frac{4}{4})$ Carbon 91·83, hydrogen 5 30, oxygen 2·87=100, corresponding to $C^{42} H^{14} O$ (or an oxydized idrialite). He derived it from the ore by sublimation in an atmosphere of carbonic acid. Bödecker states that a black material obtained from the condensation-chambers at Idria afforded a substance which has the composition of Dumas's idrialite; and this he calls *Idryl*, supposing it to be the radical of his own idrialite.

II. OXYGENATED HYDROCARBONS.

796. GEOCERITE. Geocerain *L. Brückner*, J. pr. Ch., lvii. 14, 1852.

Wax-like. Color white. Not observed to crystallize from its solution in alcohol. Melting point near 80° C.; after fusion solidifies as a yellowish wax, hard but not very brittle. Soluble in alcohol of 80 p. c. Not acted upon by a hot solution of potash.

Comp.—$\Theta_{28} H_{56} \Theta_2$, Brückner=Carbon 79·24, hydrogen 13·21, oxygen 7·55=100. Analyses Brückner (l. c.):

C	H	O
79·06	13·13	[7·81]=100.
79·16	13·01	[7·88]=100.

Obs.—From the same *dark-brown* brown coal of Gesterwitz that afforded the geomyricite (p

739), and from the same solution. The solution, after yielding the geomyricite, and next, on adding a hot solution of acetate of lead, a precipitate of a salt of lead and "geocerinsäure," finally afforded, on filtering the hot solution, the *geocerite* in the state of a jelly, which on drying became a white foliated mass.

The distillation product obtained from the same dark-brown brown coal, tallow-like in consistence (but in pearly crystals from a subsequent alcoholic solution) afforded Carbon 83·82, hydrogen 14·01, oxygen [2·17], corresponding to the formula $\Theta_{55}\,H_{110}\,\Theta$, as if derived, as follows, as Brückner states, from the above: $2\,(\Theta_{28}\,H_{56}\,\Theta_2) - (\Theta\,\Theta_2 + H_2\,\Theta) = \Theta_{55}\,H_{110}\,\Theta$. It is identical with the distillation product from the *yellowish-brown* brown coal of the same locality.

Named from γη, *earth*, and κηρος, *wax*.

797. GEOMYRICITE. Geomyricin *L. Brückner*, J. pr. Ch., lvii. 10, 1852.

Wax-like. Obtained in a pulverulent form from a solution, the grains consisting (as apparent under a microscope) of acicular crystals. Color white. Melting point 80°—83° C. After fusion has the aspect of a yellowish brittle wax. No action in a solution of potash. Soluble easily in hot absolute alcohol and ether, but slightly in alcohol of 80 p. c.

Comp., etc.—$C_{34}\,H_{68}\,O_2$, Brückner, = Carbon 80·59, hydrogen 13·42, O 5·99 = 100. **Analyses:**

	C	H	O
1. G. = 83°	80·33	13·50	[6·17]
2. G. = 83	79·97	12·85	[7·18]
3. G. = 80	80·21	13·24	[6·55]

Burns with a bright flame.

Brückner observes that the composition is very near that of the Chinese wax, Palm wax (from the S. A. palm, *Ceroxylon andicola*), Carnauba wax (from the S. A. palm, *Corypha cerifera*), for which Lewy obtained $C_{36}\,H_{72}\,O_2$ = Carbon 80·59, hydrogen 13·42, oxygen 5·99 = 100.

Obs.—Occurs at the Gesterwitz brown coal deposit, in a *dark brown* layer, similar in most respects to the *yellowish-brown* which afforded the leucopetrite. Its very slight insolubility in alcohol of 80 p. c. enabled Brückner to separate resins and other soluble ingredients present in the mass. L. Lesquereux states (priv. contrib.) that the brown coal beds of the basin in which Gesterwitz lies has afforded the palms *Flabellaria latania* and *Phœnicites Giebelianus*, and perhaps others, though none has yet been reported from the particular bed at Gesterwitz.

798. COPALITE. Fossil Copal, Highgate Resin, *Aikin*, Min., 64, 1815. Retinite pt. *Glock.*, Min., 372, 1831, *Haid.*, Handb., 574, 1845. Fossil Copal *J. F. W. Johnston*, Phil. Mag., III. xiv. 87, 1839. Copaline *Hausm.*, Handb., 1500, 1847.

Like the resin copal in hardness, color, lustre, transparency, and difficult solubility in alcohol. Color clear pale yellow to dirty gray and dirty brown. Emits a resinous aromatic odor when broken.

G. = 1·010, Johnston; 1·05, Bastock; 1·053, fr. E. Indies, Kenngott.

Comp.—Ratio for Θ, H, Θ = 40 : 64 : 1 = Carbon 85·7, hydrogen 11·4, oxygen 2·9 = 100. **Analyses:** 1, 2, Johnston (l. c.); 3, Duflos (Min. Unters., ii. 183):

	C	H	O	Ash	
1. *Yellow trp.*	85·677	11·476	2·847	——	= 100 Johnston.
2. *Gray*	85·408	11·787	2·669	0·136	= 100 Johnston.
3. E. Indies	85·73	11·50	2·77	——	= 100 Duflos.

Volatilizes in the air by a gentle heat. Burns easily with a yellow flame and much smoke, and hardly any perceptible ash. Slightly acted upon by alcohol.

Kenngott's mineral closely resembles the Highgate copalite in its honey-yellow color, and its action with heat and alcohol.

Obs.—From the blue clay (London clay) of Highgate Hill, near London, from whence it is called Highgate resin. It occurs in irregular pieces of a pale honey-yellow color.

799. SUCCINITE. Ἤλεκτρον *Homer*, etc. ? Λυγκούριον *Theophr.*, *Demostr.* Λυγγούριον *Diosc.* etc. Succinum. Electrum. Lyncurium, *Plin.*, xxxvii. 11, 12, 13. Amber. Succin. Ambre, *Fr.* Bernstein *Germ.* Succinite pt. *Breith.*, Char., 75, 1820, 140, 1823.

In irregular masses, without cleavage.

H.=2—2·5. G.=1·065—1·081. Lustre resinous. Color yellow, sometimes reddish, brownish, and whitish, often clouded. Streak white. Transparent—translucent. Tasteless. Electric on friction. Fuses at 287° C., but without becoming a flowing liquid.

Comp.—Ratio for C, H, O=40 : 64 : 4=Carbon 78·94, hydrogen 10·53, oxygen 10·53=100. **Analysis**: Schrötter (Pogg., lix. 64):

C 78·824 H 10·228 O 10·9=100.

But amber is not a simple resin. According to Berzelius (Lehrb., viii. 431, Pogg., xii. 419), it consists mainly (85 to 90 p. c.) of a resin which resists all solvents (properly *the species* succinite), along with two other resins soluble in alcohol and ether, an oil, and 2½ to 6 p. c. of succinic acid. Schrötter and Forchhammer state that after removing these soluble ingredients, true succinite has the ratio 40 : 32 : 4, which is the ratio deduced from the analyses of the whole mass, and which indicates that the mixed resins are polymerous with succinite. Their nature has not been investigated. Amber is hardly acted on by alcohol.

Burns readily with a yellow flame, emitting an agreeable odor, and leaves a black, shining, carbonaceous residue.

Obs.—Amber occurs abundantly on the Prussian coast of the Baltic; occurring from Dantzig to Memel, especially between Pillau and Dorfe Gross-Hubnicken. It occurs also on the coast of Denmark and Sweden; in Galicia, near Lemberg, and at Miszau; in Poland; in Moravia, at Boskowitz, etc.; in the Urals, Russia; near Christiania, Norway; in Switzerland, near Bâle; in France, near Paris, in clay, in the department of the Lower Alps, with bituminous coal, also in the department of l'Aisne, de la Loire, du Gard, du Bas-Rhin. In England, near London, and on the coast of Norfolk, Essex, and Suffolk. It also occurs in various parts of Asia. Also near Catania, on the Sicilian coast, sometimes of a peculiar blue tinge.

It has been found in various parts of the Green sand formation of the United States, either loosely imbedded in the soil, or engaged in marl or lignite, as at Gay Head or Martha's Vineyard, near Trenton and also at Camden in New Jersey, and at Cape Sable, near Magothy river in Maryland.

In the royal museum at Berlin there is a mass weighing 18 lbs. Another in the kingdom of Ava, India, is nearly as large as a child's head, and weighs 2¼ lbs.; it is intersected by veins of carbonate of lime, from the thickness of paper to one-twentieth of an inch.

It is now fully ascertained that amber is a vegetable resin altered by fossilization. This is inferred both from its native situation with coal, or fossil wood, and from the occurrence of insects incased in it. Of these insects, some appear evidently to have struggled after being entangled in the then viscous fluid; and occasionally a leg or wing is found some distance from the body, which had been detached in the effort to escape. Göppert has shown (Ber. Ak. Berlin, 1853, 450, Q. J. G. Soc., x., Am. J. Sci., II. xviii. 287) that at least 8 species of plants besides the *Pinites succinifer* have afforded this fossilised resin, and he enumerates 163 species as represented by remains in amber. Besides pines, species of the family *Abietineæ* and *Cupressineæ* have probably contributed to it.

Amber was early known to the ancients, and called ἤλεκτρον, *electrum*, whence, on account of its electrical susceptibilities, we have derived the word *electricity*. It was named by some lyncurium, though this name was applied by Theophrastus also to a stone, probably to zircon or tourmaline, both minerals of remarkable electrical properties.

Pliny mentions, as one proposed derivation of *electrum*, the fable, as he regards it, that the sisters of Phaëthon, changed into poplars, shed their tears on the banks of the Eridanus (or Padus), and that these tears were called *electrum*, from the fact that the sun was usually called *elector;* as another, that it comes from *Electrides*, the name of certain islands in the Adriatic: or another *electrides*, the name of certain stones in Britannia, from which it exudes. He gives it as his opinion that "amber is an exudation from trees of the pine family, like gum from the cherry, and resin from the ordinary pine;" and, as proof that it was once liquid, alludes to the gnats, etc., in it. He observes that it had been long called *succinum*, because of this origin, "quod arboris succum prisci nostri credidere." He says that in his time it was "in request among women only." But "it had been so highly valued as an object of luxury that a very diminutive human effigy, made of amber, had been known to sell at a higher price than living men, even in stout and vigorous health."

799 A. **KRANTZITE** (Fossiles Harz (fr. Nienburg), Krantzit, *C. Bergemann*, J. pr. Ch., lxxvi. 65). Essentially succinite. Occurs in small grains and masses of a light yellow or greenish-yellow color, but reddish or brownish externally. G.=0 968. Rather tender. Sectile and somewhat elastic. The exterior has G.=1·002.

Comp.—Analysis by Landolt (l. c.) afforded:

Carbon 79·25 Hydrogen 10·41 Oxygen 10·34=100.

Corresponding nearly to the formula $\mathrm{C}_{40}\,\mathrm{H}_{64}\,\mathrm{O}_4$.

Only 4 p. c. soluble in alcohol, and 6 p. c. in ether; and only softens in turpentine. In sulphuric acid gives a brown solution. Fuses at 225° C., and becomes perfectly fluid at 288°; and at a higher temperature yields gas and products of distillation. The ether solution affords a brownish amorphous substance, which is elastic like caoutchouc at 12°, and fuses at 150°.

800. WALCHOWITE.

Bergpech pt. (fr. Walchow) *Estner*, Min., iii., 1te Abth., 114, 1800. Retinit von Walchow *Schrötter*, lix. 37, 1843. Walchowit *Haid.*, Ueb., 1843, 99, Handb., 574, 1845.

In yellow translucent masses, often striped with brown. Lustre resinous. Fracture conchoidal. Translucent to opaque.

H.=1·5—2. G.=1·0—1·069; an opaque variety 1·035.

Comp.—Ratio for C, H, O=40 : 64 : 3½, Schrötter (Pogg., lix. 61)=80·41 C, 10·66 H, 8·93 O. Fuses to a yellow oil at 250° C., and burns readily; becomes transparent and elastic at 140° C. But it is a mixture, as alcohol takes up 1·5 p. c., and ether 7·5 p. c.; the *insoluble* part may be identical with the preceding. Forms a dark brown solution in sulphuric acid.

Obs.—Occurs in brown coal at Walchow, in Moravia, and formerly called *Retinite.*

Estner also mentions a honey-yellow resin from Uttigshof in Moravia (called *Bernstein* in the Abh. böhm. Ges., iii. 8), and another of a similar color, but a little greenish, from Litesko in Moravia.

801. **BUCARAMANGITE.** Resine de Bucaramanga *Boussingault*, Ann. Ch. Phys., III. vi. 507, 1842. Resembles amber in its pale yellow color. G. above 1.

Comp.—Ratio for C, H, O=42 : 66 : 2½=Carbon 82·7, hydrogen 10·8, oxygen 6·5=100.

Insoluble in alcohol. In ether softens and becomes opaque. Fuses easily, and burns with a little smoky flame, leaving no residue. Yields no succinic acid.

802. AMBRITE.

Ambrit (fr. N. Zealand) *Hochstetter*, *v. Hauer*, Verh. G. Reichs., Wien, 1861, 4.

Amorphous. In large masses.

H.=2. G.=1·034. Lustre greasy. Color yellowish-gray. Subtransparent. Strong electric on friction. Fracture conchoidal.

Comp., etc.—Ratio deduced for C, H, O=40 : 66 : 5=Carbon 76·88, hydrogen 10·54, oxygen 12·77. Von Hauer makes the ratio 32 : 26 : 4, which is not nearer the analysis than the above. Analysis: R. Maly (l. c.):

C	H	O	Ash
(⅔) 76·53	10·58	12·70	0·19

Wholly insoluble in alcohol, ether, oil of turpentine, benzole, chloroform, and dilute acid. Burns with yellow smoking flame. The ash contains iron, lime, and soda.

Obs.—Occurs in masses as large as the head in the province of Auckland, N. Zealand. It much resembles the resin of the *Dammara Australis*, which abounds on the island, and is often exported with it

803. BATHVILLITE. Bathvillite *C. Gr. Williams*, Ch. News, vii. 133, 1863. Torbanite

Amorphous. Dull, and of a fawn-brown color, looking somewhat like wood in the last stage of decay. Opaque.

G., after removing air of pores by air-pump, about 1·01. Very friable, but this characteristic may not be essential to the species. Insoluble in benzole. Torbanite has H.=2·25; G.=1·18, Heddle; color clove-brown; powder yellowish; tough.

Comp.—Ratio for Ꞓ, H, Ɵ, from the analyses, 40 : 68 : 4, or near that of succinite, =Carbon 78·43, hydrogen 11·11, oxygen 10·46=100. The ratio 40 : 66 : 4 is less near, giving the percentage C 78·7, H 10·5, O 10·8=100. Analyses: 1, Williams (l. c.); 1A, same with ash excluded; 2, Miller; 2A, same with ash excluded:

	C	H	O	Ash
1. *Bathvillite*	58·89	8·56	7·23	25·32=100.
1A. "	78·86	11·46	9·68	——=100.
2. *Torbanite*	63·10	8·91	8·21	19·78=100.
2A. "	78·67	11·11	10·22	——=100.

Williams refers here the torbanite analyzed by Miller. Other analyses of torbanite give less oxygen. The oxygen includes a little nitrogen and sulphur. Williams makes the formula Ꞓ$_{30}$, H$_{50}$ Ɵ$_{3}$=Carbon 78·60, hydrogen 10·92, oxygen 10·48, agreeing hardly as well with the analyses as the above.

Does not melt when heated. In a platinum crucible affords a fatty odor, and burns with a dense smoky flame. No action with moderately dilute nitric acid; completely carbonized by concentrated sulphuric acid.

Obs.—Bathvillite occurs in the torbanite or Boghead coal (of the Carboniferous formation), adjoining the lands of Torbanehill, in the grounds of Bathville, Scotland. It forms lumps which fill cavities in the torbanite. Other cavities are occupied by calcite, pyrite, etc. It may be an altered lump of resin; or else material which has filtrated into the cavity from the surrounding torbanite.

The analysis of Miller shows that some of the torbanite has the same composition. As proof of the absolute purity of the substances analyzed could not be had, the results are open to some doubt, as Williams observes. Yet the mode of occurrence of the bathvillite, and the nearness in composition of this insoluble substance to the equally insoluble succinite, favors the view that it is essentially a good species, and that its composition is not far from that above given.

804. TORBANITE. Torbanite, although related to cannel coal, has a very nearly uniform composition, according to all analyses thus far made, excepting that of Miller, and this composition is like that of bathvillite, excepting less oxygen. It corresponds very nearly with the formula Ꞓ$_{40}$ H$_{68}$ Ɵ$_{2\cdot25}$=Carbon 82·19, hydrogen 11·64, oxygen 6·17. The mean of five analyses (see p. 757) is, Carbon 81·15, hydrogen 11·48, with oxygen about 6·0, nitrogen 1·37=100; excluding the nitrogen, C 82·28, H 11·54, O 6·08=100. Taking the oxygen at 5·40 instead of 6·0 (see anal., l. c.), the formula would become Ꞓ$_{40}$ H$_{68}$ Ɵ$_{2}$. The nitrogen is without doubt in combination with portions of the other ingredients. But, allowing for this, the close relation to the amber group still holds, both as regards composition and insolubility. Less than 1¼ p. c. of torbanite is soluble in naphtha (Fyfe). Although the above formula cannot be taken as the formula of the species at the basis torbanite, it is probably not far from it. Torbanite may contain bathvillite as mixture

805. XYLORETINITE. Xyloretin *Forchhammer*, J. pr. Ch., xx. 459, 1840. Hartin *Schrötter* Pogg., liv. 45, 1843. Psathyrit *Glocker*, Syn., 8, 1847.

Massive, but crystallizes from a naphtha solution in needles of the orthorhombic system.

G.=1·115, hartine. Color white. Pulverizes in the fingers. Without taste or smell. Soluble in ether.

Comp, etc.—Ratio for Ꞓ, H, Ɵ=40 : 64 : 4=Carbon 78·51, hydrogen 9·05, oxygen 12·44

$C^{20} H^{17} O^{4}$, deduced by Schrötter, corresponds better with the analyses. Analyses · 1–3, Schrötter (l. c.); 4, 5, Forchhammer (l. c.):

	C	H	O	Fusing T.
1. *Hartine*	78·26	10·92	10·82=100.	210° C.
2. "	78·46	11·00	10·54=100.	
3. "	78·33	10·85	10·82=100.	
4. *Xyloretinite*	79·09	10·93	9·98=100.	165° C.
5. "	78·57	10·81	10·62=100.	

The *hartine* is a white resin separated by ether from a resin obtained from the brown coal of Oberhart. No. 1 is *hartine* as separated in an amorphous condition by means of naphtha; and 2, 3, crystallized from an ether solution. (Besides the hartine, two amorphous brown resins were also obtained from the solution.) *Xyloretinite* was derived by Forchhammer through the action of alcohol on fossil pine-wood from the marshes of Holtegaard in Denmark.

806. LEUCOPETRITE. Leucopetrin *L. Brückner*, J. pr. Ch., lvii. 1, 1852, in art. entitled Ueber einige eigenthümliche wachshaltige Braunkohlen.

Between a resin and wax in characters. Crystallizable in needles from solution.

Color of crystals white. Melting point above 100° C.; and after fusion brown and partly decomposed, and hence the exact melting point not easily determinable. Soluble in ether; also 1 part in 268 of boiling absolute alcohol; but not at all in alcohol of 80 p. c.

Comp.—$\Theta_{50} H_{84} \Theta_{3}$, Brückner,=Carbon 81·97, hydrogen 11·47, oxygen 6·56=100; very nearly $\Theta_{40} H_{67} \Theta_{2\cdot4}$. Not at all acted upon by a hot solution of potash, or cold nitric acid.

Obs.—From a layer ½–2 ft. thick, in an earthy *yellowish-brown* brown coal, at Gesterwitz, near Weissenfels. The material of the layer is of loam-like aspect, but gives a shining wax-like streak, has G.=1·297, Wackenroder, and loses 22 p. c. of water at 100° C. The dried mass is nearly half sand and other earthy materials. The leucopetrite is associated in the coaly layer, according to Brückner, with other organic compounds, soluble in alcohol of 80 p. c., including two resins, two wax-like substances (p. 738), and an acid which Brückner calls *Georetinic acid* (p. 748). By a distillation of the mass of the brown coal, 28 p. c. of the whole passes over as a butter-like mass, which is related to the paraffins, but, according to Brückner, contains 2 p. c. of oxygen. It afforded (?) Carbon 84·04, hydrogen 14·10, oxygen [1·86], and he writes the formula $\Theta_{55} H_{110} \Theta$. It is soluble easily in hot absolute alcohol and ether, and very sparingly in alcohol of 80 p. c.; crystals in pearly hexagonal plates from the alcoholic solution; melts at 50° C.

Named after the locality, Weissenfels (=white rock), from λευκός, *white*, and πετρος, *rock*.

807. EUOSMITE. Erdharz, Kampferharz, Euosmit, *C. W. Gumbel*, Jahrb. Min. 1864, 10.

Amorphous, in masses of a brownish-yellow color, or like that of cherry gum, and looking like common pitch.

H.=1·5. G.=1·2–1·5. Brittle. In thin pieces transparent. Fracture conchoidal. Strongly electric on friction. Has an odor between that of rosin and camphor. Dissolves easily in cold alcohol or ether, and hot oil of turpentine.

Comp., etc.—Ratio of Θ, H, Θ=84 : 29 : 2=40 : 68 : 2⅓=50 : 85 : 2$\frac{11}{12}$=Carbon 81·89, hydrogen 11·73, oxygen 6·38=100. Afforded 0·84 of ash. The ratio is almost identical with that of leucopetrite. Melts at 77° C., and burns with a bright flame and very aromatic odor. Solutions of the alkalies dissolve only a little of it, after long action.

Obs.—From clefts in brown coal, at Baiershof, near Thumsenreuth, in the Fichtelgebirge, and derived probably from a kind of Conifer, and one resembling the *Cupressinoxylon subæquale* Göppert.

808. SCLERETINITE. *J. W. Mallet*, Phil. Mag., IV. 4. 261, 1852.

In small drops or tears, from the size of a pea to that of a hazel-nut. H.=3. G.=1·136. Translucent in thin splinters. Color black, but by transmitted light reddish-brown; streak cinnamon-brown. Lustre between vitreous and resinous, rather brilliant. Brittle; fracture conchoidal. Insoluble in alcohol, ether, alkalies, and dilute acids.

Comp.—Analyses by J. W. Mallet (l. c.):

	C	H	O	Ash
1.	76·74	8·86	10·72	3·68
2.	77·15	9·05	10·12	3·68

Affords the ratio for Ȼ, H, Ɵ=40 : 56 : 4=Carbon 77·05, hydrogen 8·99, oxygen 10·28, ash 3·68.

Heated on platinum foil it swells up, burns like pitch, with a disagreeable empyreumatic smell, and a smoky flame, leaving a coal rather difficult to burn, and finally a little gray ash. In a glass tube yields a yellowish-brown oily product of a nauseous empyreumatic odor. Even strong nitric acid acts slowly upon it.

From the coal measures of Wigan, England.

809. PYRORETINITE. Part of Pyroretin of *A. E. Reuss*, Ber. Ak. Wien, xii. 551, 1854, J. pr. Ch., lxiii. 155; *J. Stanek*, ib. Pyroretinite *Dana*.

Resin-like. Deposited in powder from a hot alcoholic solution of pyroretin as it cools.

Comp.—Ratio of Ȼ, H, Ɵ=40 : 56 : 4=Carbon 80·00, hydrogen 9·33, oxygen 10·67=100. Analysis: Stanek (l. c.):

C 80·02 H 9·42 O [10·56]=100.

Approaches, as Stanek states, the beta-resin of the resin of *Pinus abies* (Johnston)=$\text{Ȼ}_{40}\,\text{H}_{58}\,\text{Ɵ}_{5}$, and also copaivic acid (fr. copaiba balsam) $\text{Ȼ}_{40}\,\text{H}_{60}\,\text{Ɵ}_{4}$, and other related compounds, showing that it is probably from coniferous trees.

Obs.—Pyroretin of Reuss, the resin which affords the above, occurs in the brown coal, between Salesl and Proboscht, near Aussig in Bohemia. It occurs in masses from the size of a nut to that of a man's head, and also in plates an inch thick. It is brittle; of brownish-black color; greasy-resinous lustre; wood-brown powder; H.=2·5; G.=1·05–1·18; and resembles much brown coal. It burns with a reddish-yellow flame, and a strong odor like that of burning amber, and leaves a black coal. It melts easily, decomposing and giving off white fumes, and leaves an asphalt-like mass. Reuss states evidence showing that it has probably been formed by the action of the heat of a basaltic dike on a bed of brown coal.

810. **Reussinite.** Part of Pyroretin of *A. E. Reuss*. Resin-like. Color fine reddish-brown. Soluble in boiling alcohol and in ether, and not deposited from the alcoholic solution on its cooling. Stanek (l. c.) found for the composition of the resin thus obtained, C 81·09, H 9·47, O 9·44=100; corresponding to $\text{Ȼ}_{40}\,\text{H}_{56}\,\text{Ɵ}_{3.5}$; and he regards the substance as a mixture of the above *pyroretinite*, $\text{Ȼ}_{40}\,\text{H}_{56}\,\text{Ɵ}_{4}$, with another resin (here designated *reussinite*) of the formula $\text{Ȼ}_{40}\,\text{H}_{56}\,\text{Ɵ}_{3}$.

811. ROCHLEDERITE. *Part of* Substanz Bituminose *Rochleder*, Ber. Ak. Wien, vi. 58, 1851; =Melanchym *Haid.*, Lotos, i. 85, 216, vi. 86, viii., Heft 3; *Kenng.*, Ueb. 1850, 147, 1853, 134. Rochlederite *Dana*.

Resin-like. Color reddish-brown. Transparent or translucent. Melting point 100° C. Soluble in alcohol.

Comp.—Ratio of Ȼ, H, Ɵ=40 : 56 : 6. Analysis: Rochleder (l. c.):

C 76·79 H 9·06 O 14·15=100.

Burns with a yellow smoking flame, something like amber.

Obs.—The part soluble in alcohol of a bituminous substance called melanchyme by Haidinger and found in masses as large as the head in the brown coal of Zweifelsreuth, near Neukirchen in Eger, Bohemia. A similar substance, of somewhat lighter color, occurs at Oehnitz, near Strakonitz, in Bohemia.

The rest of the substance insoluble in alcohol is the species melanellite, p. 750.

812. SCHLANITE. Part of Anthracoxen of *Reuss* (see p. 746). Schlanite *Dana.*

A dark or light brown powder, obtained through solution by ether from anthracoxene.

Comp.—Ratio for Ꞓ, H, Θ=40 : 52 : 3½=Carbon 81·63, hydrogen 8·85, oxygen 9·52=100. **Analysis:** Laurens (l. c., p. 746):

(⅓) C 81·47 H 8·71 O 9·82=100.

This resin oxydizes slowly when wet and exposed to the air.

Obs.—For locality and description of the material affording the schlanite, see p. 746.

813. GUYAQUILLITE. *Johnston*, Phil. Mag., xiii. 329, 1838.

Amorphous. In large masses or layers.

Yields easily to the knife, and may be rubbed to powder. G.=1·092. Color pale yellow. Lustre not resinous, or imperfectly so. Slightly soluble in water, and largely in alcohol, forming a yellow solution, which is intensely bitter.

Comp., etc.—Ratio for Ꞓ, H, Θ=40 : 52 : 6=Carbon 76·665, hydrogen 8·174, oxygen 15·161 =100, Johnston. Begins to melt at 69½° C., but does not flow easily till near 100° C. As it cools becomes viscid, and may be drawn into fine tenacious threads. Soluble in cold sulphuric acid, forming a dark reddish-brown solution. A few drops of ammonia put into the alcoholic solution darken the color, and finally change it to a dark brownish-red.

It is said to form an extensive deposit near Guyaquil in South America. Evidently a mixture.

814. MIDDLETONITE. *J. F. W. Johnston*, Phil. Mag., III. xii. 261, 1838.

In rounded masses, seldom larger than a pea, or in layers a sixteenth of an inch or less in thickness, between layers of coal.

Brittle. G.=1·6. Lustre resinous. Color reddish-brown by reflected light, and deep red by transmitted; powder light brown. Transparent in small fragments. No taste or smell. Blackens on exposure. Only a trace dissolved by boiling alcohol, ether, or oil of turpentine. Not altered at 210° C.

Comp., etc.—Ratio for Ꞓ, H, Θ=40 : 44 : 2, Johnston,=Carbon 86·33, hydrogen 7·92, oxygen 5·75=100. Johnston obtained (⅓) Carbon 86·21, hydrogen 8·03, oxygen 5·76=100.

On a red cinder burns like resin. Softens and melts in boiling nitric acid, with the emission of red fumes; a brown flocky precipitate falls on cooling. Soluble in cold concentrated sulphuric acid.

Obs.—Occurs between layers of coal about the middle of the Main coal or Haigh Moor seam, at the Middleton collieries, near Leeds, in thin layers and masses, rarely thicker than 1/16 in., and little rounded masses seldom larger than a pea; also at Newcastle.

815. STANEKITE. Part of Pyroretin of *A. E. Reuss*, Ber. Ak. Wien, xii. 551, 1854, J. pr. Ch., lxiii. 155; *J. Stanek*, ib. Stanekite *Dana.*

Resin-like. Not soluble in any fluid without decomposition, and not at all in a solution of potash. Separated from the pyroretin of Reuss by boiling alcohol, which leaves it behind.

Comp.—Ratio of Ɵ, H, Ɵ=39 : 44 : 6, Stanek,=Carbon 76·97, hydrogen 7·24, oxygen 15·79 =100. Perhaps Ɵ, H, Ɵ=40 : 44 : 6=Carbon 77·42, hydrogen 7·09, oxygen 15·48=100. **Analysis**: Stanek (l. c):

(⅔) C 76·71 H 7·30 O 15·99=100.

When heated gives off the odor of succinic acid.

Obs.—For locality and characters of the pyroretin of Reuss, affording the above, see p. 744.

816. ANTHRACOXENITE. Part of Anthracoxen (fr. Brandeisl) *Reuss*, *T. Laurenz*, Ber. Ak. Wien, xxi. 271, 1856, J. pr. Ch., lxix. 428, 1856. Anthracoxenite *Dana*.

Obtained as a black powder from a resin, by separating the remainder by means of ether, the anthracoxenite being insoluble in ether.

Comp.—Ratio of Ɵ, H, Ɵ=40 : 38 : 7½. **Analysis**: Laurenz (l. c.):

(⅔) C 75·274 H 6·187 O 18·539.

11 p. c. of ash were separated. Not soluble in menstrua without decomposition.

Obs.—From a resin-like material, constituting layers 2½ in. thick between layers of coal, in the coal beds of Brandeisl, near Schlan in Bohemia; the mass is amorphous, and has H. = 2·5; G.=1·181; lustre externally weak adamantine; color brownish-black, hyacinth-red in thin splinters by transmitted light; streak dull, yellowish-brown; fracture small-conchoidal; easily rubbed to a fine powder; fuses easily; burns with a yellow smoking flame, and an odor not disagreeable. This substance was named *anthracoxene* by Reuss. The name is here appropriated to the part insoluble in ether. The soluble part is named schlanite (p. 745).

---

817. TASMANITE. Resiniferous Shale (fr. Tasmania), Catal. Internat. Exhib., 1862. Tasmanite *A. H. Church*, Phil. Mag., IV. xxviii. 465, 1864.

In disks or scales thickly disseminated through a laminated shale; average diameter of scales about ·03 in.

H.=2. G.=1·18. Lustre resinous. Color reddish-brown. Translucent. Fracture conchoidal. Not dissolved at all by alcohol, ether, benzole, turpentine, or bisulphid of carbon, even when heated.

Comp., etc.—No action with muriatic acid. Slowly oxydized by nitric. Readily carbonized by sulphuric acid, with evolution of sulphuretted hydrogen. Alkalies in solution without action. Burns readily with a smoky flame and offensive odor; fuses partially, yielding oily and solid products, having a disagreeable smell. Ratio of Ɵ, H, Ɵ, S=40 : 62 : 2 : 1=Carbon 79·21, hydrogen 10·23, sulphur 5·28, oxygen 5·28=100, corresponding nearly to succinite, in which part of the oxygen is replaced by sulphur. **Analysis**: Church (l. c.), after rejecting 8·14 p. c. of ash:

C 79·34 H 10·41 S 5·32 O 4·93

Obs.—From the river Mersey, north side of Tasmania. The rock is called *combustible shale*.

A caking bituminous coal from New Zealand, analyzed by C. Tookey in the laboratory of Prof. Percy (see anal. 18, p. 757), contained 2·37 p. c. of sulphur and *no* iron, the ash being peculiarly white; and Percy remarks (Met., 101, 102) that the sulphur may have been present in a state similar to that in fibrine. The existence of a sulphur-bearing resin like the above from Tasmania renders it probable that the New Zealand coal is impregnated with a similar insoluble resin; 2·37 p. c. of sulphur would correspond to the presence of about 44 p. c. of such a resin.

818. DYSODILE. (fr. Melili, Sicily) *Paulo Boccone*, Recherches et Obs. Nouv., etc., Amsterd. 1674. Dysodile *Cordier*, J. d. M., xxiii. 275, 1808. Merda di Diavolo *Ital.* Stinkkohle *Germ.* Houille papyracée, Tourbe papyracée, *Fr.*

In very thin leaves or folia, flexible, slightly elastic.
G.=1·14–1·25. Color yellow or greenish-gray. Streak shining.

Comp., etc.—Very inflammable, burning with a bright flame and an odor like that of assafœtida, leaving an ash in the form of laminæ, consisting largely, as shown by Ehrenberg, of the siliceous shells of infusoria, especially of Naviculæ. Delesse found (Thèse anal. Chim., 1, 1843) a variety from Glimbach, near Giessen, to afford water and volatile matters 49·1, carbon 5·5, ash 45·4; of the last, 17·4 were soluble silica, 11·0 sesquioxyd of iron, and 10·0 clay. Very probably near tasmanite, as Church suggests.

Obs.—Originally from Melili, Sicily, forming a coaly deposit, made up of very thin paper-like leaves, which had evidently been derived from the joint decomposition and alteration of vegetable and animal matter. Reported also from the lignite deposits of Westerwald near Rolt; of Siegberg to the north of Sept Montagnes; of Saint Armand in Auvergne; Glimbach near Giessen; but the real nature of none of these substances has been investigated.

819. HIRCITE. Hircine *Piddington*, Arch. Pharm., lxxiv. 318, Kenng. Ueb., 1853, 134.

Amorphous.
G.=1·10. Color exteriorly brown, within yellowish-brown. Subtranslucent to opaque. Fracture conchoidal. Softens in boiling water, and then has the odor of a resin. In cold alcohol a little soluble; in boiling about one-half, and the solution, which is gold-yellow, affords white flocks on cooling.

Pyr., etc.—In the flame of a candle fuses and burns with a yellowish flame, like a bituminous coal, and leaves a tough coaly globule of a peculiarly strong animal odor (whence the name, from *hircus, a goat*). After complete combustion, leaves an ash. In sulphuric acid soluble, and color of solution blood-red.

820. BAIKERINITE. Part of Baikerit, Dickflussiges Harz, *Hermann* (see p. 783). A thick tar-like fluid at 15° C., and a crystalline granular deposit in a viscid honey-like mass at 10° C. Color brown. Translucent. Odor balsamic. Taste like that of wood-tar. Easily and perfectly soluble in alcohol and ether. The alcoholic solution becomes milky when diluted with water.

Constitutes 32·61 p. c. of the baikerite. No analysis yet made.

820A. DOPPLERITE of *J. C. Deicke*, B. H. Ztg., xvii. 383. (Not Dopplerite according to *Kenng.*, Ueb. 1858, 141.) Grayish, earthy, plastic in the fingers when fresh; becoming dark reddish-brown to black on drying.

Yields after drying, combustible substance 83·25, water 12·5, ash 4·25. Burns with a bright flame and intense heat, and differs from dopplerite in this respect, and also in containing much less water.

From a peat bed at Finkenbach in the Canton of St. Gall, Switzerland.

III. ACID HYDROCARBONS.

821. BUTYRELLITE. Bog Butter *Luck*, Ann. Ch. Pharm., liv. 125, 1845. Butyrit *Glocker*, Syn., 9, 1847. Butyro-limnodic Acid *Brazier*, Chem. Gaz., 1852, 375. Butyrellite *Dana*.

Crystallizable in needles. Butter-like in consistence. Color white. Melting point of impure native material 47°, Brazier; but of material after solution in alcohol 51°, Luck; 52°–52·7°, Brazier. Easily soluble in alcohol or ether.

Comp.—$\mathrm{Є}\ ,\mathrm{H}_{64}\,\Theta_4$, Brazier=Carbon 75·0, hydrogen 12·5, oxygen 12·5=100, and like palmitic acid in ratio. Luck gives the less probable formula $\text{C}_{33}\,\text{H}_{66}\,\Theta_4$. The following are Luck's analyses (l. c.): Nos. 1, 2, were the uncrystallized butyrite; 3, that obtained by combination with potash (with which it forms a kind of soap) and a separation afterward by acid:

	C	H	O
1. *Uncrystallized*	73·78	12·50	13·72=100.
2. "	73·89	12·37	13·74=100.
3. From potash solution	75·05	12·56	12·39=100.

Obs.—From the peat-bogs of Ireland.

The name butyrite being used in chemistry for another substance, it is here changed to the form above.

822. GEOCERELLITE. Geocerinsäure *Brückner*, J. pr. Ch., lvii. 10, 1852. Geoceric Acid. Geocerellite *Dana*.

Color white. Brittle, and easily pulverized. No crystallization observed. Soluble freely in hot alcohol, and deposited from the solution as a jelly on cooling, with nothing crystalline under the microscope. Melting point 82° C.

Comp.—$\text{C}_{28}\,\text{H}_{56}\,\Theta_4$, Brückner; =Carbon 79·24, hydrogen 13·21, oxygen 7·55=100. **Analysis**: Brückner (l. c.):

(½) Carbon 78·61 Hydrogen 12·70 Oxygen 18·69=100.

The acid was separated by combination with lead by action with a hot solution of acetate of lead.

Obs.—Separated from the *dark brown* brown coal of Gesterwitz. See GEOCERITE, p. 738.

823. BRÜCKNERELLITE. Georetinsäure *Brückner*, J. pr. Ch. lvii. 5, 1852. Georetinic Acid. Brücknerellite *Dana*.

Crystallizable in white needles from an alcoholic solution. Dissolves easily in boiling alcohol; and, if the solution is a concentrated one, crystallizes out more or less completely on cooling.

Comp.—$\text{C}_{24}\,\text{H}_{44}\,\Theta_8$, Brückner, =Carbon 62·61, hydrogen 9·56, oxygen 27·83=100. The lead salt afforded Carbon 43·36, hydrogen 6·59, oxyd of lead 34·58, oxygen [15·47]=100.

Obs.—Separated from the yellowish-brown brown coal of Gesterwitz. See LEUCOPETRITE, p. 743.

824. SUCCINELLITE. [Succinum] vertitur [by distillation] partim in oleum sui coloris, partim denique in *candidum quiddam et tenue* quod similitudinem quandam gerit speciemque salis, *Agric.*, Nat. Foss., 238, 1546. Flos Succini *Libav.*, Alchem. Tract., 399, 1597. Succinic Acid. Succinellite *Dana*.

Orthorhombic. $I \wedge I = 120°\ 18'$, $O \wedge 1 = 129°\ 45'$; $a : b : c = 1{\cdot}0425 : 1 : 1{\cdot}7425$, Ramm. 1 : 1, bas.,=100° 30′, macr., 135°, brach., 96° 22′.

H.=1. G.=1·55. Lustre vitreous. Colorless or white. An aromatic odor. Soluble in water.

Comp.—$\text{C}_4\,\text{H}_6\,\Theta_4$=Carbon 40·7, hydrogen 5·1, oxygen 54·2=100. Evaporates at a low temperature, and on cooling condenses in crystals.

Obs.—Exists in amber, constituting 2½ to 6 p. c. of the mass, and easily obtained from it by distillation. Its presence ready formed in this resin is shown by the fact that it may be separated either by water, ether, or alkalies, the amber being left after the treatment without its succinic acid.

825. RETINELLITE. *Part of* Bright Yellow Loam (fr. Bovey) so saturated with petroleum that it burns like sealing-wax, *J. Milles*, Phil. Trans., li. 536, 1760; Bitumen from Bovey, Retin asphaltum, *Hatchett*, ib., 1804, 402; Retinite. Resin of Retin Asphalt, Retinic Acid, *J. F. W. Johnston*, Phil. Mag., III. xii. 560, 1838. Retinellite *Dana*.

Resin-like. Light brown. Begins to melt at 121° C., is perfectly fluid at 160°, and gives off a resin-like odor at 100° C. Soluble in alcohol, still more freely in ether.

Comp.—O. ratio for Θ, H, Θ=21 : 28 : 3. **Analysis:** Johnston (l. c.):

C 76·86 H 8·75 O 14·39=100.

Johnston describes salts of retinic acid with silver, lead, and lime.

Obs.—The retinasphalt of Hatchett, from the Tertiary coal of Bovey in Devonshire, from which alcohol separates the above species, occurs in roundish masses, having H.=1—2·5; G.=1·135, Hatchett; lustre slightly resinous in the fracture, often earthy externally; color light yellowish-brown, sometimes green, yellow, reddish, or striped; and is subtransparent to opaque; often flexible and elastic when first dug up, though brittle on drying. Johnston, after drying the retinasphalt at 300° C., obtained (l. c.) 53·92 p. c. of resin soluble in alcohol, 27·45 of insoluble organic matter, and 18·23 of ash=100. The insoluble portion has not been investigated.

Hatchett found (l. c.) vegetable resin 55, bitumen 41 (the insoluble part, which he regarded as asphalt, and alludes to in the name retinasphalt), and earthy matter 3=99.

A retinite from Halle afforded Bucholz (Schweig. J., i. 290, 1811) 91 parts soluble in absolute alcohol, and 9 parts insoluble. The *former* gives a yellowish-brown deposit on dilution, and is more soluble in boiling dilute alcohol than in cold; and it is insoluble in pure ether and turpentine. The *latter* is also insoluble in ether. Both are soluble in alkalies, which would seem to indicate that they are acid in their relations.

The resin fuses with more difficulty than most resins, blackens in the heat, and gives out a strong aromatic odor. By distillation yields a brown thick oil, some water containing a little acetic acid, besides carbonic acid and carburetted hydrogen.

826. DOPPLERITE. Dopplerit *Haid.*, Ber. Ak. Wien, ii. 287, 1849, iii. 281.

Amorphous. In elastic or partly jelly-like masses. When fresh, brownish-black, with a dull brown streak and greasy subvitreous lustre; and when in thin plates reddish-brown by transmitted light.

H.=0·5. G.=1·089, Fœtterle. After drying, H.=2—2·5, G.=1·466, and lustre somewhat adamantine. Becomes elastic on drying from exposure to the air. Tasteless. Insoluble in alcohol or ether.

Comp., etc.—Ratio for Θ, H, Θ, nearly 10 : 12 : 5, from analyses 2, 8. An acid substance, or mixture of different acids, related to humic acid. Analyses: 1, Schrötter (Ber. Ak. Wien, ii. 287, 1849); 2, 3, F. Mühlberg (Jahrb. G. Reichs., xv. 283, 1865):

	C	H	O	N	
1. Aussee	51·09	5·29	42·59	1·03	=100 Schrötter.
2. "	55·94	5·20	38·86		=100 Mühlberg.
3. Obbürg (§)	56·63	5·58	37·79		=100 Mühlberg.

From No. 1, 5·86 of ash are excluded; from No. 2, 5·18; from 3, 5 to 14·2 p. c. All were dried. Schrötter found the loss of water 78·5 p. c.; and Mühlberg, at 110° C, for No. 2, 20·04 p. c. for an air-dried specimen; for 8, 81·8 p. c. for a jelly-like specimen, and 19·7 for an air-dried. In caustic potash soluble, with a residue of earthy matters.

Obs.—Found in peat-beds, near Aussee in Styria; and in Gontin in Appenzell, and Obbürg, near Stansstad in Unterwalden, Switzerland.

Named after Bergrath Doppler, who was the first to bring the substance to notice.

C. W. Gümbel has referred here (Jahrb. Min. 1858, 278) a substance from a peat-bed near Berchtesgaden. It is soft, plastic, elastic, black, of waxy lustre, tasteless; on drying in the air it resembles compact coal, is brittle and velvet-black, and has H.=2·5, G.=1·439, lustre vitreous, with powder brownish-black. The air-dried material loses, at 80° C., 12 p. c. of water. Unlike dopplerite, it burns with a bright yellow flame, is partially soluble in alcohol, and the alcoholic solution affords a resin (Kenng. Ueb., 1858, 142).

A pitch-black coal-like substance from the peat-beds at Kolbenmoor, near Berchtesgaden, the same that are described by Gümbel, related to dopplerite in composition, and in *not burning* with a flame when inserted in fragments in the flame of a candle, has been analyzed by C. Gilbert Wheeler (priv. contrib., dated Nuremberg, Jan. 23, 1866). It afforded him:

C 50·98 H 5·36 N 3·74 O 36·14 ash 3·78=100.

It appears to be the same substance that is here partially described by Gümbel.

Mr. Wheeler observes that it is found imbedded in, and entirely surrounded by, the peat; and specimens show well the transition from peat to the coal-like substance.

827. **MELANELLITE.** Part of Melanchym of *Haid.* (see p. 744). Melanellite *Dana.*

Black and gelatinous, as obtained by Rochleder. Separated from rochlederite, or the resinous ingredient of melanchyme, by dissolving the latter out by means of alcohol.

Comp., etc.—The jelly-like mass gave on analysis, Carbon 67·14, hydrogen 4·79, oxygen 28·07=100, corresponding to the ratio 48 : 40 : 15=Carbon 67·3, hydrogen 4·7, oxygen 28·0=100. The ratio 48 : 40 : 16=12 : 10 : 4 affords the percentage C 66 1, H 4·6, O 29·3=100. The substance is regarded by Rochleder as an acid related to ulmic acid. But, as it was not combined with a base before analysis, there is no proof of its purity.

On the locality and material affording this acid, see ROCHLEDERITE, p. 744.

IV. SALTS OF ORGANIC ACIDS.

828. **MELLITE.** Honigstein (fr. Thuringia) *Wern.*, Bergm. J., 1789, i. 380, 395. Honigstein *Karst.*, Mus. Lesk., ii. P. 1, 335, 1789. Succin transparent en cristaux octaèdres, Pierre de miel, *v. Born*, Cat. de Raab, ii. 90, 1790. Mellites *Gmelin*, Linn. Syst., iii. 282, 1793. Mellilite *Kirwan*, Min., ii. 68, 1796. Mellite *H.*, iii. 1801. Honigstein, Melilithus,=Honigsteinsäure (Acidum melilithicum)+Alaunerde+Wasser, *Klapr.*, Ak. Berlin, 1799, Beitr., iii. 114, 1801.

Tetragonal. $O \wedge 1=33°\ 29'$; $a=0·745445$, Kokscharof. Occurs in octahedrons, with often the planes *i-i* truncating the basal angles, and sometimes the terminal angle and basal edges truncated, the occurring planes being *O*, *I*, *i-i*, 1. $1 \wedge 1$, pyr.,$=118°\ 16'$, basal,$=93°\ 1\frac{1}{2}'$; $1 \wedge i\text{-}i=121°\ 52'$. Cleavage: octahedral, very indistinct. Also in massive nodules, granular in structure.

H.=2—2·5. G.=1·55—1·65; 1·636—1·642, Kenngott. Lustre resinous, inclining to vitreous. Color honey-yellow, often reddish or brownish; rarely white. Streak white. Transparent—translucent. Fracture conchoidal. Sectile.

Comp.—$\ddot{\text{Al}}\,\bar{\text{M}}^3+18\,\dot{\text{H}}$=Mellitic acid 40·53, alumina 14·32, water 45·15. **Analyses:** 1, Klaproth (Beitr., iii 114); 2, Wöhler (Pogg., vii. 325); 3, J. v. Iljenkof (Koksch., iii. 217):

Mellitic acid	46	41·4	42·36
Alumina	16	14·5	14·20
Water	38=100 K.	44·1=100 W.	44·16 I.

Pyr., etc.—Whitens in the flame of a candle, but does not take fire. Dissolves in nitric acid; decomposed by boiling water. In a matrass yields water.

Obs.—Occurs in brown coal at Arten in Thuringia; at Luschitz near Bilin in Bohemia; near Walchow in Moravia; in the Govt. of Tula, Russia in Europe; Nertschinsk, beyond Lake Baikal.

829. PIGOTITE *Johnston* (Phil. Mag., III. xvii 382). A salt of alumina and an organic acid called mudoscous acid by Johnston. Composition $4\,\ddot{\text{Al}}+\Theta_6\text{H}_{10}\Theta_4$ (the acid)$+27\,\dot{\text{H}}$. Formed on granite, in Cornwall, from the action of wet vegetation. Reported also from Wicklow (Ch. Gaz., 1852, 378).

829A. ORGANIC SALTS OF IRON. Native compounds of iron and organic acids have been indicated by Berzelius and other chemists as common in marshes. But none of them has yet been properly investigated, the kinds of acids, as well as the proportions of acid to bases, being undetermined.

APPENDIX TO HYDROCARBONS.

830. ASPHALTUM. ʼΑσφαλτος *Aristot.*, *Strabo*, *Diosc.*, etc. Bitumen *Plin.*, xxxv. 51. Asphalt, Mineral Pitch. Asphalt, Bergpech, Erdpech, *Germ.* Asphalte, Bitume, *Fr.* [For syn. of Pittasphalt or Mineral Tar (Bergtheer *Germ.*), see p. 728.]

Asphaltum, or mineral pitch, is a mixture of different hydrocarbons, part of which are oxygenated. Its ordinary characters are as follows:

Amorphous. G.=1—1·8; sometimes higher from impurities. Lustre like that of black pitch. Color brownish-black and black. Odor bituminous. Melts ordinarily at 90° to 100° C., and burns with a bright flame. Soluble mostly or wholly in oil of turpentine, and partly or wholly in ether; commonly partly in alcohol.

The more solid kinds graduate into the pittasphalts or mineral tar (p. 728), and through these there is a gradation to petroleum. The fluid kinds change into the solid by the loss of a vaporizable portion on exposure, and also by a process of oxydation, which consists first in a loss of hydrogen, and finally in the oxygenation of a portion of the mass.

Comp.—The action of heat, alcohol, ether, naphtha, and oil of turpentine, as well as direct analyses, show that the so-called asphaltum from different localities is very various in composition. Yet the true composition is not known of any one of them. It has been shown only that the following are the classes of ingredients present:

A. *Oils* vaporizable at about 100° C., or below; sparingly present, if at all.

B. *Heavy oils*, probably of the Pittolium or Petrolene groups (pp. 728, 729); vaporizable between 100° and 250° C.; constituting sometimes 85 p. c. of the mass.

C. *Resins* soluble in alcohol.

D. *Solid asphalt-like substance or substances soluble in ether and not in alcohol;* black, pitch-like, lustrous in fracture; 15 to 85 p. c.

E. *Black or brownish-black substance or substances not soluble either in alcohol or ether;* similar to D in color and appearance, Kersten; brown and ulmin-like, Völckel; 1 to 75 p. c.

F. Nitrogenous substances; often as much as corresponds to 1 or 2 p. c. of nitrogen.

Boussingault attempted an investigation of the composition in 1837 (Ann. Ch. Phys., lxiv. 141), and arrived at the conclusion that there were two principles present; one *petrolène*, an oil, the other *asphaltène*, a solid, and concluded that all asphalts were mixtures of these two in different proportions. But his *petrolene*, as already observed, is beyond question a mixture of oils; and his *asphaltene* needs much more investigation. His special examinations on this point were made only on the asphalt of Becholbronn. He found in it (1) no light oil (or A), as nothing was given off at 100° C.; (2) 85·4 p. c. of heavier oil, or his *petrolene*, vaporized between 100° and 230° C. (B); and (3) 14·6 p. c. of a black, lustrous, asphalt-like solid, his *asphaltene*, soluble in *ether*, oil of turpentine, and fatty oils, but not in alcohol (D). Asphaltene was the solid substance after subjecting the asphaltum to a temperature of 250° C. in a hot oil-bath.

(Boussingault has been quoted by Berzelius, Kersten, Rammelsberg, and others, as making the asphaltene *not* soluble in ether, but he expressly mentions its solubility. He also states earlier that the *mass* of the asphalt was *wholly* soluble in ether; and, also, that he used ether to separate it from the impurities present, after which kind of purification it burnt without residue.)

Boussingault's analysis of asphaltene afforded:

Carbon 75·0 Hydrogen 9·9 Oxygen 14·8=99·7;

giving the ratio for Ɵ, H, Ɵ=40 : 64 : 6. He closes the paper with his analysis of an asphalt (the mass) from Caxitambo, as follows:

C 75·0 H 9·5 O 15·5=100;

and remarks on the near approach of this alphalt in composition to *asphaltene*. But in 1840 (l. c., lxxiii. 444) he gives two new analyses of the Caxitambo asphalt, in which he obtained only 1·65 of oxygen and nitrogen (see anal. 7, below); and adds that "his earlier analysis was made by the method ordinarily followed at that time, by which method he was never able to obtain more than 76 p. c. of carbon." The remark virtually concedes the inaccuracy of the analysis also of asphaltene, or at least gives sufficient occasion for a very large doubt. No special mention is made in this second paper of the asphalt of Bechelbronn, but analyses are given of *petrolene* from the locality.

Nendtvich, in an investigation of an asphalt from Peklenicza, Austria, found it to consist almost solely of *asphaltene*, that is, it was soluble in ether and not in alcohol; and in 1843 (Jahrb. G. Reichs., vii. 743) obtained for it nearly the composition of asphaltene (or C 72·45, H 11·07 O 16·48); but in 1847 (Haid. Ber., iii. 271) he rejects his earlier results, and states that the mineral contained *no oxygen*, and was essentially identical in composition with petrolene, as stated on p. 730.

Other analysts have not afforded more satisfactory results. Part have been contented with analyses of the undivided mass; while others have ascertained the portions soluble in different menstrua, without ascertaining the constituents of the substances obtained.

The following table contains the proportions of the ingredients A, B, C, D, E, above, in a few asphalts. The letters E and A, in connection with the statement of the solubility, stand for *ether* and *alcohol*. 1, Boussingault (l. c.); 2, Kersten (J. pr. Ch., xxxv. 271); 3, 4, Völckel (Ann. Ch. Pharm., lxxxvii. 189); 5, Klaproth (Beitr., iii. 315); 6, Meyrac (J. d. Phys., xcix. 118); 7, Hermann (J. pr. Ch., lxxiii. 232); 8, Nendtvich (Haid. Ber., l. c.):

	A. Light oils.	B. Heavier oils.	C. Resin.	D. Sol. in E. Insol. in A.	E. Insol. in E & A.

3. Dax	*very little*			*about half*	*about half*	Völckel.
4. Travers, near Neufchatel	"			"	"	Völckel.
5. Albania	0	0	0	*all*	0	Klaproth.
6. Bastennes			*two thirds*		*a third*	Meyrac.
7. Tschetschna, Caucasus		11·2	0	88·8	0 =100	Hermann.
8. Peklenicza		*trace*		*all*	0	Nendtvich.

Klaproth found the asphalt of Avlona, Albania, to give nothing to alcohol, and to dissolve completely in ether, like that of Peklenicza.

It is probable that the material insoluble in both alcohol and ether (column E, above) is not always of the same kind. That from the Brazza asphalt (anal. 2) was black and lustrous, asphalt-like; while that of Dax (anal. 3) was brown, and ulmin-like.

Ultimate analyses of different asphalts have afforded the following results: 1–3, Ebelmen (Ann. d. M., xv. 528); 4, 5, Regnault (Ann. d. M., III. xii. 161); 6, Wetherill (Trans. Am. Phil. Soc. Philad., 1852, 353); 7, Boussingault (l. c., lxxxiii. 444):

	C	H	O	N	Ash	
1. Bastennes	78·50	8·80	[2·60]	1·65	8·45=100	Ebelmen.
2. Pont du Chateau	76·13	9·41	[10·34]	2·32	1·80=100	Ebelmen.

5. Cuba	81·46	9·57	[8·97]		——=100	Regnault.
6. "	82·34	9·10	[6·25]	1·91	0·40=100	Wetherill.
7. Caxitambo	(?) 88·66	9·69	[1·65]		——=100	Boussingault.

The most of these analyses need revision.

Obs.—Asphaltum belongs to rocks of no particular age. The most abundant deposits are superficial. But these are generally, if not always, connected with rock deposits containing some kind of bituminous material or vegetable remains (see p. 725).

Some of the noted localities of asphaltum are the region of the Dead Sea, or Lake Asphaltites, whence the most of the asphaltum of ancient writers; a lake on Trinidad, 1¼ m. in circuit, which is hot at the centre, but is solid and cold toward the shores, and has its borders over a breadth of ¾ m. covered with the hardened pitch with trees flourishing over it; and about Point La Braye, the masses of pitch look like black rocks among the foliage; at various places in S. America, similar lakes, as at Caxitambo (not Coxitambo), Peru, which is used at Payta, on the coast (under the equator), for pitching boats, etc.; at Berengela, Peru, not far from Arica (S.), where it is put to the same use; in California, near the coast of St. Barbara, an area of some acres; in a large bed, near Avlona in Albania (G.=1·205). Also in smaller quantities, sometimes disseminated through shale and sandstone rocks, and occasionally limestones, or collected in cavities or seams in these rocks· near Matlock Derbyshire, in stalactitic masses; Poldice mine in Cornwall; Haughmond Hill in Shropshire; at Bastennes and Dax, Dept. of Landes, constituting 6 p. c. of a sandy deposit; Val de Travers, Neuchatel, impregnating a bed in the Cretaceous formation, and serving as a cement to the rock, which is used for buildings; impregnating dolomite on the island of Brazza in Dalmatia; in the Caucasus; in gneiss and mica schist in Sweden.

The following substances are closely related to asphaltum, and, like it, are mixtures of undetermined carbohydrogens.

830A. Grahamite *Wurtz* (Coal or Asphalt *Lesley*, Proc. Am. Phil. Soc. Philad., ix. 183, 1863; Grahamite *Wurtz*, Rep. Min. Format. in W. Virginia, 1865, Am. J. Sci., II. xlii. 420, 1866.) Resembles the preceding in its pitch-black, lustrous appearance; H.=2; G.=1·145. Soluble mostly in oil of turpentine; partly in ether, naphtha, or benzole; not at all in alcohol; wholly in chloroform and sulphid of carbon. No action with alkalies or hot nitric or muriatic acid. Melts only imperfectly, and with a decomposition of the surface; but in this state the interior may be drawn into long threads.

Occurs in W. Virginia, about 20 m. in an air line S. of Parkersburg, filling a fissure (shrinkage fissure) in a sandstone of the Carboniferous formation; and supposed to be, like the albertite, an inspissated and oxygenated petroleum. There is yet no reliable analysis of it, not even an ultimate analysis. The material is partly columnar from a fracturing as a result of contraction in the material, the structure being vertical to the sides of the vein.

830B Albertite *Robb.* (Melan-Asphalt *Wetherill*, Trans. Am. Phil. Soc. Philad., 1852, 353.) Differs from ordinary asphaltum in being only partially soluble in oil of turpentine, and in its very imperfect fusion when heated. It has H.=1—2; G.=1·097; lustre brilliant, pitch-like; color jet-black. Softens a little in boiling water; in the flame of a candle shows incipient fusion. According to imperfect determinations, only a trace soluble in alcohol; 4 p. c. in ether; 30 in oil of turpentine.

Wetherill obtained in an ultimate analysis (l. c.) Carbon 86·04, hydrogen 8·96, oxygen 1·97, nitrogen 2·93, S *tr.*, ash 0·10=100. By destructive distillation, oils of the Naphtha, Betanaphtha, and Ethylene series have been obtained by Warren.

Occurs filling an irregular fissure in rocks of the Subcarboniferous age (or Lower Carboniferous) in Nova Scotia, and is regarded as an inspissated and oxygenated petroleum. For an article on its mode of occurrence, see Hitchcock, Am. J. Sci., II. xxxix. 267.

830C. Piauzite (Retinit von Piauze, Piauzit, *Haid.*, Pogg., lxii. 275, 1844). An asphalt-like substance, remarkable for its high melting-point, 315° C. It occurs slaty massive; color brownish-or greenish-black; thin splinters colophonite-brown by transmitted light; streak light brown, amber-brown; H.=1·5; G.=1·220; 1·186, Kenngott.

After melting, it burns with an aromatic odor and much smoke, leaving 5·96 per cent. of ash. Soluble in ether and caustic potash, also largely in absolute alcohol. Heated in a glass tube a yellowish oily fluid is distilled, having an acid reaction.

It comes from a bed of brown coal at Piauze, near Neustadt in Carniola; on Mt. Chum, near Tüffer in Styria, where thousands of pounds have been obtained. It much resembles a black lamellar coal (Kenngott, Jahrb. G. Reichs., 91, 1856).

830D. Berengelite *Johnston*, Phil. Mag., III. xiii. 329, 1838. Asphaltum-like. Color dark brown, with a tinge of green. Powder yellow. Lustre of surface of fracture resinous.

Analysis: Johnston (l. c.): C 72·47, H 9·20, O 18·33=100, corresponding to the ratio for Ꞓ, H, Ɵ, 40 : 62 : 8. Forms a solution with cold alcohol, which is bitter to the taste. On evaporation the resin obtained has a clear red color, and remains soft and viscid at the ordinary temperature. Nearly insoluble in caustic potash. Odor resinous, disagreeable; but after fusion for some time at 100° C., this odor is succeeded by an agreeable one; on cooling it regains the original odor. It is said to form a lake like that of Trinidad, in the province of St. Juan de Berengela, about 100 m. from Arica, Peru, and is used at Arica for paying boats and vessels.

831. MINERAL COAL. *Ἀνθρακευτὰ δ'ὅσα τῶν τοιούτων γῆς πλέον ἔχει ἢ καπνοῦ* [=Coal-like substances which have in them more of earth than of smoke or fire] *Aristot.*, Μετεωρολογ.. iv. 9. Οὓς *δὲ καλοῦσιν εὐθὺς ἄνθρακας τῶν θρυπτομένων* (? *ὀρυττομένων*) *διὰ τὴν χρείαν εἰσὶ γεώδεις*, etc. [=Those (of minerals) dug for use, which are called simply coals, are earthy, but will kindle and burn like charcoal] (fr. Liguria), *Theophr.*, xvi. (in Schneider's edit.), 315 B.C. *Ἔνιοι δὲ τῶν θραυστῶν ἀνθρακοῦνται τῇ καύσει καὶ διαμένουσι πλείω χρόνον* [=Some brittle stones become by burning like glowing coals, and remain so a long time] (fr. Bena in Thracia, and the promontory of Erineas) *Theophr.*, xii. Θρακίας λίθος *Aristot.* Γαγγίτης λίθος *Strabo* Γαγάτη λίθος, Θρακίας λίθος, *Diosc.*, v. 145, 146. Thracius lapis, Gemma Sammothracia, *Plin.*, xxxiii 30, xxxvii. 67. Gagates *Plin.*, xxxvi. 34. Steinkohle *Germ.* Houille, Charbon fossile, *Fr.*

Mineral coal is made up of different kinds of hydrocarbons, with perhaps in some cases free carbon; but the species have not yet been investigated.

The distinguishing characters of mineral coal are as follows:

Compact massive, without crystalline structure or cleavage; sometimes breaking with a degree of regularity, but from a jointed rather than a cleavage structure. Sometimes laminated; often faintly and delicately banded, successive layers differing slightly in lustre.

H.=0·5—2·5. G.=1—1·80. Lustre dull to brilliant, and either earthy, resinous, or submetallic. Color black, grayish-black, brownish-black, and occasionally iridescent; also sometimes dark brown. Opaque. Fracture conchoidal—uneven. Brittle; rarely somewhat sectile. Without taste, except from impurities present. Insoluble in alcohol, ether, naphtha, and benzole, excepting at the most 2 or 3 p. c. (rarely 10?); usually less than 1 p. c. Insoluble in a solution of potash. Infusible to subfusible; but often becoming a soft, pliant, or paste-like mass when heated. On distillation most kinds afford more or less of oily and tarry substances, which are mixtures of hydrocarbons and paraffin.

Var.—The variations depend partly (1) on the amount of the volatile ingredients afforded on destructive distillation: or (2) on the nature of these volatile compounds, for ingredients of similar composition may differ widely in volatility, etc.; (3) on structure, lustre, and other physical characters.

1. ANTHRACITE (Anthracit *Karst.*, Tab., 58, 96, 1808. Glanzkohle *Germ.*). H.=2—2·5. G.=1·32—1·7, Pennsylvania; 1·81, Rhode Island; 1·26—1·36, South Wales. Lustre bright, often submetallic, iron-black, and frequently iridescent. Fracture conchoidal. Volatile matter after drying 3 to 6 p. c. Burns with a feeble flame of a pale color.

The anthracites of Pennsylvania contain ordinarily 85 to 93 per cent. of carbon; those of South Wales, 88 to 95; of France, 80 to 83; of Saxony, 81; of southern Russia, sometimes 94 per cent.

Anthracite graduates into bituminous coal, becoming less hard and containing more volatile matter; and an intermediate variety is called *free-burning* anthracite.

2. *Native Coke.* More compact than artificial coke, and some varieties afford considerable bitumen. From the Edgehill mines, near Richmond, Va., according to Genth, who attributes its origin to the action of a trap eruption on bituminous coal.

BITUMINOUS COALS (Schwarzkohle *Hausm.*, Handb., 73, 1813. Steinkohle pt. *Germ.*). Under the head of Bituminous Coals, a number of kinds are included which differ strikingly in the action of heat, and which therefore are of unlike constitution. They have the common characteristic of burning in the fire with a yellow, smoky flame, and giving out on distillation hydrocarbon oils or tar, and hence the name *bituminous*. The *ordinary* bituminous coals contain from 5 to 15 p. c. (rarely 16 or 17) of oxygen (ash excluded); while the so-called *brown coal* or *lignite* contains from 20 to 36 p. c., after the expulsion, at 100° C., of 15 to 36 p. c. of water. The amount of hydrogen in each is from 4 to 7 p. c. Both have usually a bright, pitchy, greasy lustre (whence often called *Pechkohle* in German), a firm compact texture, are rather fragile compared with anthracite, and have G.=1·14—1·40. The *brown* coals have often a brownish-black color, whence the name, and more oxygen, but in these respects and others they shade into ordinary bituminous coals.

The ordinary bituminous coal of Pennsylvania has G.=1·26—1·37; of Newcastle, England, 1·27; of Scotland, 1·27—1·32; of France, 1·2—1·33; of Belgium, 1·27—1·3. The most prominent kinds are the following:

3. CAKING COAL. A bituminous coal which softens and becomes pasty or semi-viscid in the fire. This softening takes place at the temperature of incipient decomposition, and is attended with the escape of bubbles of gas. On increasing the heat, the volatile products which result from the ultimate decomposition of the softened mass are driven off, and a coherent, grayish-black, cellular, or fritted mass (*coke*) is left. Amount of coke left (or part not volatile) varies from 50 to 85 p. c. A caking coal will lose its caking quality if kept heated for 2 or 3 hours at 300° C., and sometimes on mere exposure for a time to the air.

4. **Non-Caking Coal.** Like the preceding in all external characters, and often in ultimate composition; but burning freely without softening or any appearance of incipient fusion. Percentage of volatile matter same as for caking coal, but the *coke* is not a proper coke, being in powder, or of the form of the original coal.

There are all gradations between caking and non-caking bituminous coals. In external characters the two kinds are alike. They often break into layers: and there is besides a horizontal banding arising from a succession of very thin *non-separable* layers, slightly differing in lustre or shade of color. *Cherry coal* or *soft coal* (of England) is a non-caking coal igniting well and burning rapidly, while *splint* or *hard coal* ignites less readily, burns less rapidly, owing to the smaller amount of volatile matter. Coals which do not cake on burning are called *free-burning* coals while the caking are called *binding* coals.

5. **Cannel Coal** (Parrot Coal). A variety of bituminous coal, and often caking; but differing from the preceding in texture, and to some extent in composition, as shown by its products or distillation. It is compact, with little or no lustre, and without any appearance of a banded structure; and it breaks with a conchoidal fracture and smooth surfaces; color dull black or grayish-black. On distillation it affords, after drying, 40 to 66 of volatile matter, and the material volatilized includes a large proportion of burning and lubricating oils, much larger than the above kinds of bituminous coal; whence it is extensively used for the manufacture of such oils It graduates into oil-producing coaly shales, the more compact of which it much resembles. The original *Parrot coal* is a cannel from near Edinburgh, which burns with a crackling noise, whence the name (Percy); and *Horn coal*, a kind from South Wales, which emits when burning something of the odor of burning horn.

6. **Torbanite.** A variety of cannel coal of a dark brown color, yellowish streak, without lustre, having a subconchoidal fracture; H.=2·25; G.=1·17—1·2. Yields over 60 p. c. of volatile matter, and is used for the production of burning and lubricating oils, paraffin, illuminating gas. Named from the locality at Torbane Hill, near Bathgate in Linlithgowshire, Scotland. Also called *Boghead Cannel* (see p. 742).

7. **Brown Coal** (Braunkohle *Germ.*, Pechkohle pt. *Germ.*, Lignite). The prominent characteristics of brown coal have already been mentioned. They are non-caking, but afford a large proportion of volatile matter. They are sometimes pitch-black (whence Pechkohle pt. *Germ.*), but often rather dull and brownish-black. G.=1·15—1·3; sometimes higher from impurities. It is occasionally somewhat lamellar in structure.

Brown coal is often called *lignite*. But this term is sometimes restricted to masses of coal which still retain the form of the original wood. *Jet* is a black variety of brown coal, compact in texture, and taking a good polish, whence its use in jewelry.

8. **Earthy Brown Coal** (*Erdige Braunkohle*) is a brown friable material, sometimes forming layers in beds of brown coal. But it is in general not a true coal, a considerable part of it being soluble in ether and benzole, and often even in alcohol; besides affording largely of oils and paraffin on distillation. For a notice of "coal" of this kind see under Leucopetrite, p. 743 Such a coal is sometimes called *wax coal* and *paraffin coal* (Wachskohle, Paraffinkohle, *Germ.*). See also Bathvillite, p. 742.

9. **Mineral Charcoal.** Fibrous charcoal-like substance often found covering the surfaces between layers of coal, and observed in coal of all ages. It is soft, and soils the fingers like charcoal. One variety of it is a dry powder.

Comp.—Most mineral coal consists mainly, as the best chemists now hold, of *oxygenated hydrocarbons*. On page 742 it is shown that the kind of cannel coal called *torbanite* and the substance *bathvillite* are closely related in composition, as well as insolubility, to the species of the Succinite group; and it is probable that other cannel coals contain this or some related compound; and that oil-producing (not oil-bearing) shales include a similar kind of hydrocarbon. The ordinary bituminous coals often have 10 to 15 p. c. of oxygen, and may be of analogous composition, though differing much in the precise constitution of these hydrocarbons, some containing such as produce a pasty fusion or incipient decomposition when heated (caking), and others such as undergo no semi-fusion (non-caking). The brown coals, in which there are 20 to 35 p. c. of oxygen, must include other kinds of oxygenated hydrocarbons, of the insoluble kinds. But microscopic examinations appear to show that woody fibre is present in it in various stages of alteration.

Besides oxygenated hydrocarbons, there may also be present *simple hydrocarbons* (that is, containing no oxygen). This would seem to follow from the small percentage of oxygen (2—3 p. c.) in the Tyneside cannel, while the hydrogen is as large in amount as in any cannel or bituminous coals. And there are various bituminous coals, low in oxygen, that suggest the same conclusion. At present, however, chemistry knows of no simple hydrocarbons that are insoluble in naphtha and benzole.

The presence of *free carbon* is naturally inferred from the composition of coals like the anthracites, which afford very little volatile matter. But even these coals contain ordinarily 1·5 to 2·5 p. c. of each oxygen and hydrogen; and Berthelot holds that they are hydrocarbon compounds like other coals. It is remarkable that in one of the analyses of anthracite from Piesberg, Hanover (anal. 4), no oxygen whatever was found, while there were 2·23 p. c. of hydrogen.

The portion of coal soluble in naphtha or benzole, although small in amount, indicates the presence of other hydrocarbons—simple or oxygenated—oils or resins. Their nature remains to be ascertained. Fyfe obtained by means of naphtha, from the Torbane mineral, 1·2 and 1·4 p. c.; from cannel coal, 2—4 p. c.; and from Newcastle caking, in three experiments, 4·2, 5·8, 9·8 p. c. of soluble material. These results do not accord with the ordinary statements with regard to the insolubility of coal, and the subject needs far more extended study.

Under microscopic examination, when in thin slices, many bituminous coals (including most cannel coals, the gas coals of Nova Scotia, Pelton, etc.) are seen to consist of *three kinds* of material, as first observed by Hutton (Geol. Soc. London, 1832–33), and further more particularly by Dr. Aitken of Glasgow (Ronalds & Richardson, Chem. Techn., i. 778).

(1) An opaque black substance, which is insoluble in acids as well as other menstrua, and, as suggested, may be free carbon (?). It is stated to be the main constituent of anthracite.

(2) A yellow or reddish resin-like substance, which is translucent or transparent, volatile by heat, and insoluble in naphtha, muriatic and nitric acids.

(3) Earthy matter, which is more or less soluble in water, and is earthy impurity.

The resin like material, No. 2, may well be a species of the Succinite group (see above). In many pitchy bituminous coals it is impossible to make out the structure here described, on account of their opacity. Some Nova Scotia coal contains yellow matter, which is soluble in ether, and slightly so in turpentine and nitric acid; and the same is true of that of the Pelton coal. Many *brown* coals, as the Bovey, show the structure above described.

Coals often contain *resins* disseminated in *visible* points through the mass, which may or may not be of soluble kinds.

Sulphur is present in nearly all coals. It is supposed to be usually combined with iron, and when the coal affords a *red ash* on burning, there is reason for believing this true. But Percy mentions a coal from New Zealand (anal. 18) which gave a peculiarly white ash, although containing 2 to 3 p. c. of sulphur, a fact showing that it is present not as a sulphid of iron, but as a constituent of an organic compound. The discovery by Church of a resin containing sulphur (see TASMANITE, p. 746), gives reason for inferring that it may exist in this coal in that state, although its presence as a constituent of other organic compounds is quite possible.

The presence of *nitrogen*, sometimes 2 p. c., proves the presence of nitrogenous hydrocarbons; but of what nature is unknown.

The above review of the composition of coal shows that as yet very little is known as to its actual constituents; and that no analyses to determine them can be satisfactory which are not carried forward by the aid of the microscope, and by the preparatory separation of the coal into parts, as far as possible, by different menstrua, and the separate analyses of these parts.

The impurities present, which constitute the *ash* of the coal, consist of silica or quartz, oxyd of iron, clay, and other aluminous silicates, or such ingredients as make up the mud and clay of fine soil or alluvium; also some silica, potash, and soda, derived from the original vegetation. The ash in the purest mineral coal amounts to but 0·25 to 1 p. c.; but in that which passes for the best there are ordinarily 5 to 8 p. c.; and in most that is used for fuel there are 8 to 15 p. c.

Analyses: *Anthracite.* 1, Regnault (Ann. d. M., III. xii.): 2–4, Hilkenkamp & Kempner (Steink. Deutschl., ii. 284, 1865); 5, Regnault (l. c.); 6, 7, J. Percy (Proc. G. Soc., i. 202, Metal'gy, 105, 1861).

Caking coal. 8–10, Stein (Steink. Sachs., 1857); 11, Regnault (l. c.); 12, 13, Dick (Percy's Met., 99); 14, C. Tookey (ib.); 15–17, Noad (ib.): 18, C. Tookey (ib.); 19–21, Regnault (l. c.); 22, 23, Marsilly (C. R., xlvi. 891).

Non-caking. 24, Regnault (l. c.); 25, Nendtvich (Ber. Ak. Wien, 1851); 26, 27, A. Dick (Percy's Met., 102); 28, 29, Rowney (Edinb. N. Phil. J., ii. 141, 1855); 30, Stein (l. c.); 31–34 Marsilly (l. c.); 35, E. Riley (Percy's Met., 102).

Whether caking or not, not stated. 36-39, Fleck (Steink. Deutschl., ii. 272, 1865).

Cannel coal. 40, Regnault (l. c.); 41, Vaux (J. Ch. Soc., i. 320); 42, Taylor (Edinb. N. Phil. J., i. 145, 1851).

Torbanite. 43, Anderson (Greg & Lettsom, Min., 17); 44, Hofmann (ib.); 45, Stenhouse (ib.); 46, Fife (ib.); 47, Metter (J. pr. Ch., lxxvii. 38).

Brown coal. 48–51, Regnault (l. c.); 52, F. Vaux (J. Ch. Soc., v. 1, 318, 1849); 53, Nendtvich (l. c.); 54, Gräger (Jahresb. 1848, 261); 55, Schrötter (Jahresb. 1849, 708); 56, Baer (Jahresb. 1852, 733); 57, F. Bischof (B. H. Ztg. 1850, 69); 58, Wagner (Polyt. Centralbl. 1847, 1496); 59 F. Bischof (l. c.); 60, Liebig (Kenngott, 1852, 257); 61, Woskressensky (ib.).

Mineral charcoal. 62–65, Dr. Rowney (l. c.).

Anthracite.

Coal occurs in beds, interstratified with shales, sandstones, and conglomerates, and sometimes limestones, forming distinct layers, which vary from a fraction of an inch to 30 feet or more in thickness. In the United States, the anthracites occur east of the Alleghany range, in rocks that have undergone great contortions and fracturings, while the bituminous are found farther west, in rocks that have been less disturbed; and this fact and other observations have led some geologists to the view that the anthracites have lost their bitumen by the action of heat. For observations on the geological relations of coal beds, reference may be made to geological treatises.

The *origin* of coal is mainly vegetable, though animal life has contributed somewhat to the result. The beds were once beds of vegetation, analogous, in most respects, in mode of formation to the peat beds of modern times, yet in mode of burial often of a very different character. This vegetable origin is proved not only by the occurrence of the leaves, stems, and logs of plants in the coal, but also by the presence throughout its texture, in many cases, of the forms of the original fibres; also by the direct observation that peat is a transition state between unaltered vegetable debris and brown coal, being sometimes found passing completely into true brown coal. *Peat* differs from true coal in want of homogeneity, it visibly containing vegetable fibres only partially altered; and wherever changed to a fine-textured homogeneous material, even though [illegible]lly consolidated, it may be true brown coal.

The derivation of coal from woody fibre has been explained in a general way on page [illegible] From the statements there made it is obvious that the vegetable material, in changing to ordinary mineral coal, has not passed necessarily through the stage of brown coal. When the materia was long steeped in water, and buried under fine mud so as to exclude almost entirely atmospheric air, the decomposition in progress may have carried off most of the oxygen by its combination with the carbon of the plants, to form carbonic acid. Thus it happened probably with the cannel coals, as explained by Newberry, and also, though in general less perfectly, with most of the best bituminous coals. But when the bed had as free access to the air as occurs in the case of peat beds, there would have been a loss of carbon and hydrogen as marsh-gas, and also, probably, through combination with external oxygen, forming carbonic acid and water, while a large part of the oxygen would remain. Between these extremes, of excluded air and very imperfectly excluded, and of pressure from heavy superincumbent earthy beds and little or no pressure, lie the conditions which attended the origin of the various kinds of coal, and determined, in connection with the nature of the vegetation itself, the transformations in progress.

Extensive beds of mineral coal occur in Great Britain, covering about $\frac{1}{10}$ the whole area, or 11,859 square miles; in France about $\frac{1}{120}$, or 1719 sq. m.; in Spain about $\frac{1}{50}$, or 3408 sq. m.; in Belgium $\frac{1}{22}$, or 518 sq. m.; in Netherlands, Prussia, Bavaria, Austria, northern Italy, Silesia, Spain, Russia on the south near the Azof, and also in the Altai. It is found in Asia, abundantly in China, in Persia in the Cabul territory, and in the Khorassan or northern Persia, in Hindostan, north of the Gulf of Cutch, in the province of Bengal (the Burdwan coal field) and Upper Assam, in Borneo, Labuan, Sumatra, several of the Philippines, Formosa, Japan, New South Wales and other parts of Australia, New Zealand, Kerguelen's Land; in America, besides the United States, in Chili, at the Straits of Magellan, northwest America on Vancouver's Island near the harbor of Camosack, at Bellingham Bay in Puget's Sound, at Melville Island in the Arctic seas, and in the British Provinces of Nova Scotia, New Brunswick, and Newfoundland.

In the United States there are four separate coal areas. One of these areas, the Appalachian coal field, commences on the north, in Pennsylvania and southeastern Ohio, and sweeping south over western Virginia and eastern Kentucky and Tennessee to the west of the Appalachians, or partly involved in their ridges, it continues to Alabama near Tuscaloosa, where a bed of coal has been opened. It has been estimated to cover 60,000 sq. m. It embraces several isolated patches in the eastern half of Pennsylvania. The whole surface in Pennsylvania has been estimated at 15,437 sq. m., or $\frac{1}{3}$ the whole area of the State. A second coal area (the Illinois) lies adjoining the Mississippi, and covers the larger part of Illinois, though much broken into patches, and a small northwest part of Kentucky; it is continued westward over a portion of Iowa, Missouri, Kansas, Arkansas, and northern Texas west of the Mississippi. The latter area is divided along the Mississippi by a narrow belt of Silurian rock; the whole area is about the same with that of the Appalachian coal field. A third covers the central portion of Michigan, not far from 5000 sq. m. in area. Besides these, there is a smaller coal region (a fourth) in Rhode Island, which crops out across the north end of the island of Rhode Island, and appears to the northward as far as Mansfield, Massachusetts. The total area of coal measures in the United States is about 125,000 sq. m.

Out of the borders of the United States, on the northeast, commences a fifth coal area, that of Nova Scotia and New Brunswick, which covers, in connection with that of Newfoundland, 18,000 sq. m., or $\frac{1}{5}$ the whole area of these provinces.

The mines of western Pennsylvania commencing with those of the Blossburg basin, Tioga Co., those of the States west, and those of Cumberland or Frostburg, Maryland, Richmond or Chesterfield, Va., and other mines south, are *bituminous*. Those of eastern Pennsylvania constituting several detached areas—one, the *Schuylkill* coal field, on the south, worked principally at Mauch Chunk on the Lehigh, and at Pottsville on the Schuylkill—another, the *Wyoming* coal field, worked at Carbondale, in the Lackawanna region, and near Wyoming, besides others intermediate—those of Rhode Island and Massachusetts, and some patches in Virginia, are *anthracites*. Cannel coal is found near Greensburg, Beaver Co., Pa., in Kenawha Co., Va., at Peytona, etc.; also in Kentucky, Ohio, Illinois, Missouri, and Indiana; but part of the so-called cannel is a coaly shale.

In England, the principal coal fields are the Manchester of Lancashire and Cheshire; the Great Central of South Yorkshire, Nottingham, and Derby; that of South Wales, Glamorganshire, etc.; the Newcastle field of northern England. In Scotland, a range of beds extends across from the Firth of Forth to the Firth of Clyde; whole area 1650 sq. m. In Ireland, the three are the Limerick fields about the mouth of the Shannon, the Kilkenny fields to the eastward, and that of Ulster on the north. Cannel coal occurs in Great Britain at Lesmahago in Lanarkshire, about 20 m. from Glasgow; also near Wigan in Lancashire, and West Wemyss in Fyfe.

Mineral coal occurs in France, in small basins, 88 in number, and covering in all, according to Taylor, $\frac{1}{117}$ of the whole surface. The most important are the basin of the Loire, between the Loire and the Rhone, and that of Valenciennes on the north, adjoining Belgium. In Belgium, it occupies a western and eastern division, the western in the provinces of Namur and Hainault, and the eastern extending over Liege.

Brown coal comes from coal beds more recent than those of the Carboniferous age. But much of this more recent coal is not distinguishable from other bituminous coals. The coal of Richmond, Virginia, is supposed to be of the Liassic or Triassic era; the coal of Brora, in Sutherland, and of Bovey, Yorkshire, is Oolitic in age. Tertiary coal occurs on the Cowlitz, in Oregon (anal. 14), and in many places over the eastern slopes of the Rocky Mountains, where a "Lignitic formation" is very widely distributed; but it is rarely in beds of economical importance.

The coal known to the Greeks and Romans was probably brown coal. The first sentence, in the synonymy, from Aristotle evidently alludes to mineral coal of some kind; and the first of the two cited from Theophrastus (a favorite pupil of Aristotle) refers to a similar substance, and perhaps the same specimens. The locality of the latter, Liguria (or northwestern Italy along the Mediterranean), where, he adds, there also is amber, may be taken with some freedom, as articles brought by vessels trading with Ligurian ports, even though coming from French ports beyond, might be referred to Liguria. Elis, on the way to Olympias, is given as another locality. The sentence ends with the statement that "these coals are used by the smiths," showing that the value of the substance as fuel was well understood at the time (4th century B.C.). Theophrastus says further, that it will continue to burn as long as any one blows it, but on stopping it deadens, but may be made to burn again; and that it burns with a strong disagreeable odor. The second citation from each, Aristotle and Theophrastus, relates to a similar coal. The locality, in Thrace, identifies it with the *Thracian stone* of Dioscorides and Pliny, the locality of which, according to the former (from Aristotle), was at Sintia, on the river Pontus (on the Macedonian border of Thracia, to the west of the present Constantinople). According to Dioscorides and Pliny (quoting further in part from Aristotle's "Wonderful Things heard of"), water would make the Thracian stone to burn, and oil extinguish it; which is either altogether a fable, or a partial truth based on somebody's observation that masses or piles of impure pyritiferous coal will become hot, and sometimes ignited, in consequence of being wet. Aristotle mentions its bituminous odor when burning.

The *Gagates* (whence our word *jet*) occurred, according to Dioscorides and Pliny, at Gagas or Gages, a place in Lycia (Asia Minor). The former describes it as black, smooth, and combustible, to which Pliny adds, that it was light, and looked much like wood, and that it emitted a disagreeable odor when rubbed, and burned with the smell of sulphur. It was, in part at least, true lignite. Lignite is common in Syria, in the rocks of Mt. Lebanon, as near Beirut; and beds of coal have been recently opened in Asia Minor.

Some of the works or memoirs on coal economically considered are the following: Report to Congress on Coals, by W. R. Johnson, 1844; Statistics of Coal, by R. C. Taylor, 8vo, 2d. ed., Philadelphia, 1855; Report to the British Government on Coals, by De la Beche & Playfair, 1851; Ronalds & Richardson's Chemical Technology, Vol. I. on Fuel and its Applications, London, 1855; Percy's Metallurgy, London, 1861; Chem. Unters. d. Steinkohlen Sachsen's, by W. Stein, Leipzig, 1857; Die Steinkohlen Deutschland's und anderer Länder Europa's, etc., by Geinitz, Fleck & Hartig, 3 vols., 4to, München, 1865.

SPECIES OF UNCERTAIN PLACE IN THE SYSTEM.

832. AZORITE. New mineral from the Azores *J. E. Teschemacher*, Am. J. Sci., II. iii. 32, 1847
Azorite *Dana*, this Min., 396, 681, 1850.

Tetragonal. In minute octahedrons, with the basal edges replaced; angle of pyramid (by reflective goniometer) 123° 15′, $M \wedge e = 133° 40′$. Cleavage none.

H.=4—4·5. Translucent to opaque. White, with a faint greenish-yellow tinge, or colorless. Vitreous in fracture.

Comp.—According to A. A. Hayes, columbate of lime. B.B. infusible; smaller crystals become opaque white; larger in outer flame reddish, and light yellow in inner. With borax, on platinum wire, dissolves with extreme slowness and difficulty to a transparent globule, sometimes faint greenish; with more borax opaque on flaming. With salt of phosphorus slowly dissolved, producing a faint green color.

Obs.—From the Azores, in an albitic rock, along with black tourmaline and pyrrhite. First distinguished and described by J. E. Teschemacher. The largest crystal seen was but 1¼ lines in diameter. There is some resemblance in form to cryptolite (p. 529), but a re-examination of the species by Mr. Hayes corroborates his first announcement that the mineral contains neither cerium nor phosphoric acid.

The angle 123° 15′ is near that of zircon, and it is possible that it is that species. But Teschemacher says of its hardness, that "it just scratches fluor spar."

833. BREWSTERLINITE. A new fluid in the cavities of minerals *D. Brewster*, Ed. Phil. J., ix. 1828; Trans. R. Soc. Edinb., x. 1, 407, 1826; Am. J. Sci., vii. 186, 1824, xii. 214 (with a plate), 1827; Phil. Mag., IV. xxv. 174, 1863. Brewsterline *Dana*, Min., 559, 1850; Brewstoline, ib., 471, 1854.

In a vacuum (or as it occurs in the cavities of crystals) a colorless transparent fluid, adhering but slightly to the enclosing mineral, and hence very voluble; expanding about one-fourth with an increase of 16⅔° C. (30° F.), or between 10° and 27° C. (50° and 80° F.), 21 times more expansible than water; index of refraction 1·2106, for the fluid from an amethyst from Siberia; 1·1311 for a kind from a topaz; boiling point in a vacuum from 23° to 29° C. (74° to 84° F.), the fluid filling the cavities with the warmth of the hand or mouth.

On exposure to the air undergoes rapid movements, spreading over the surface and contracting again, and then dries to separate particles or grains, which are lustrous and appear to be opaque, but are transparent by transmitted light; by the approach of moisture, even the moisture of the hand, even after being dry for some days, becomes liquid again, and renews its rapid movements. Soluble without effervescence in sulphuric, nitric, and muriatic acids. Volatilized by heat.

Comp.—Unknown. The effect of moisture on the dry grains shows that the substance is no' one of the hydrocarbon oils, or a resin.

Obs.—Occurs in cavities of topaz crystals from Brazil, Scotland and Australia, of chrysoberyl, of quartz crystals from Quebec, amethyst from Siberia, and first described by Sir David Brewster

The cavities are mostly microscopic, but occasionally ¼ in. across, or even larger. They are generally arranged in layers, and are sometimes counted by thousands in a single crystal. Brewster counted 30,000 in a chrysoberyl ⅙ in. square. The strata run irregularly with reference to the symmetry of the crystal, often intersect one another, and are sometimes curved; it is rare that 3 or 4 strata are parallel. The very low refracting power, less than that of water, is a remarkable character of the fluid (the refraction index of water being 1·336; of alcohol 1·361; of ether 1·358). The fluid from a quartz crystal from Quebec, which exploded with much force when heated, had a disagreeable taste.

In his original memoir Brewster states that the fluid was 32 times more expansible than water, but in the later reference to it in 1863 (Phil. Mag., l. c.) makes it 21 times.

The lower index of refraction, 1·1311, obtained for the fluid of a topaz, is so much below the other, 1·2106, that it may indicate a distinct species.

834. CRYPTOLINITE. A new fluid, etc., *Brewster* (see for ref., BREWSTERLINITE). Cryptoline *Dana*, Min., 559, 1850.

A colorless transparent fluid, as observed in the cavities of crystals, like brewsterlinite, but more dense; adhering like water to the enclosing surfaces; expansibility about that of water; index of refraction 1·2946. Not soluble in, or a solvent of, brewsterlinite, the two, when occurring together, not being miscible.

On exposure to the air hardens speedily to a resin-like substance; brilliant in lustre; yellowish; transparent; absorbent of moisture, but much less so than brewsterlinite; insoluble in water and alcohol; rapidly dissolved with effervescence by sulphuric acid, and soluble also in nitric and muriatic acids; not volatilized by heat.

Comp.—Nothing is known.

Obs.—Occurs in the same crystals, and generally the same cavities, with brewsterlinite. This denser of the two fluids, according to Brewster, occupies the angles of the cavities, or the necks or narrow passages which unite two or more large cavities, while the other rarer fluid floats on it, and fills the rest of the cavity, excepting a circular vacuity, occupied only by this fluid in the gaseous state, if at all.

835. HESSENBERGITE. Hessenbergit *Kenng.*, Ber. Ak. München, 1863, ii. 230. Sideroxen *Hessenb.*, Min. Not., No. 7, 1866.

Monoclinic. $C=89°\ 53'=O \wedge i\text{-}i$; $I \wedge I=59°\ 27'$, $O \wedge \frac{1}{2}\text{-}\grave{\imath}=152°\ 20\frac{1}{2}'$; $a : b : c=0·59843 : 1 : 0·570967$. Observed planes: O; vertical, I, $i\text{-}i$, $i\text{-}\grave{\imath}$, $i\text{-}3$, $i\text{-}9$; clinodome, $\frac{1}{2}\text{-}\grave{\imath}$; hemidomes, $1\text{-}i$, $\frac{5}{4}\text{-}i$, $3\text{-}i$, $-1\text{-}i$; hemioctahedral, $\frac{3}{2}\text{-}3$.

$O \wedge I=90°\ 3\frac{1}{2}'$
$O \wedge i\text{-}3=90\ \ 6$
$O \wedge 1\text{-}i=149$

$i\text{-}3 \wedge i\text{-}3=119°\ 27'$
$i\text{-}i \wedge 3\text{-}i=150\ \ 51$
$O \wedge -1\text{-}i=149\ \ 8$

$i\text{-}i \wedge \frac{5}{4}\text{-}i$, calc., $=126°\ 43'$
$i\text{-}i \wedge \frac{5}{4}\text{-}i$, obs., $=127\ \ 35$
$I \wedge i\text{-}\grave{\imath}=150\ \ 16\frac{1}{2}$

Simple crystals unknown. Twins: composition-face $-1\text{-}i$; $I \wedge I_{,}=150°\ 39\frac{1}{2}'$, $i\text{-}i \wedge i\text{-}i_{,}=118°\ 2'$, $O \wedge O_{,}=61°\ 44'$.

H.=7–7·5. Lustre adamantine. Colorless, bluish. Transparent.

Comp.—A silicate of undetermined constituents.

Pyr., etc.—In a closed tube yields no water, and is unchanged. In the platinum forceps whitens, but does not fuse. In borax melts without intumescence. Heated with cobalt solution becomes gray. No action from muriatic acid.

Obs.—Occurs implanted on crystals of hematite (*Eisenrose*) at Mt Fibia, west of the Hospice of St. Gothard. The habit a little after that of euclase.

Named after F. Hessenberg, the crystallographer, of Frankfort on the Main.

836. PARATHORITE. Thorite *Shep.*, Proc. Am. Assoc., ii. 321, 1850. Parathorite *Shep.* Min., 287, 1857; *Dana*, *Brush*, Am. J. Sci., xxiv. 124, 1857.

Orthorhombic. In minute rectangular and rhombic prisms, with the planes I, $i\text{-}\bar{\imath}$, $i\text{-}\breve{\imath}$; $I \wedge I = 128°$, $I \wedge i\text{-}\breve{\imath} = 116°$.

H.=5—5·5. Lustre subresinous. Color garnet-red to pitch-black; thin edges of black crystals with a ruby translucence, a little like rutile. Translucent to opaque.

Comp., Pyr., etc.—In the matrass decrepitates slightly, but does not appear to contain water. B.B. in the platinum forceps glows, fuses with difficulty on the edges, and becomes paler. In borax dissolves to a bead, which is yellow, from iron, while hot, and becomes colorless on cooling. With salt of phosphorus gives in the outer flame a bead, yellow while hot and colorless on cooling. In the inner flame the bead assumes a delicate violet color (due to titanic acid?), Brush.

Obs.—Occurs imbedded in danburite and orthoclase, and only in very minute crystals, at Danbury, Ct.

Shepard made the crystallization erroneously tetragonal. There are also other discrepancies in his description, which might lead to the supposition that the mineral here described is a different mineral from Shepard's; but the evidence to the contrary is complete.

837. PYRRHITE. *G. Rose*, Pogg., xlviii. 562. 1840.

Isometric; in octahedrons. Cleavage not observed.

H.=6. Lustre vitreous. Color orange-yellow. Subtranslucent.

Pyr., etc.—B.B. infusible, but blackens, and colors the flame deep yellow. In fragments difficultly soluble in salt of phosphorus, but in fine powder it is readily taken up by this salt, as well as by borax, forming a clear glass when cold if only a small portion is used, while if saturated it is yellowish-green, becoming somewhat more intense in R.F. Fused with soda on charcoal, it spreads out and is absorbed by the coal, giving a slight white coating, somewhat resembling oxyd of zinc; it yields no metallic spangles when the surface of the coal is removed and rubbed in the mortar. Insoluble in muriatic acid (G. Rose).

Obs.—Pyrrhite was found by von Perovski of St. Petersburg at Alabaschka, near Mursinsk in the Ural, where it occurs in drusy feldspar cavities, containing also lepidolite, albite, and topaz. The largest crystal was but three lines long.

Named from πυῤῥός, *yellowish-red* or *fire-like*.

With this species J. E. Teschemacher identifies small orange-red, monometric octahedrons, found with albite at the Azores (J. Nat. H. Bost., iv. 499, 1844; Proc. id., ii. 108, 1846). along with tetragonal octahedrons of *azorite* (p. 761). The crystals are a half to two lines long, and those of minute size are transparent.

According to chemical and blowpipe trials by A. A. Hayes (Am. J. Sci., II. ix. 423) on specimens furnished him by Mr. Teschemacher, these crystals consist of columbate of zirconia, colored apparently by oxyds of iron, uranium, and manganese.

B.B. in the forceps, on the first impulse of the heat, becomes darker, and the fine orange color returns on cooling, even if the heat has been high; at the melting point of cast iron, in the reduction flame, the flame becomes permanently darker and brown. With borax (6 parts to 1 of assay) it dissolves, and affords a clear colorless glass, which becomes instantly opaline or opaque on flaming; transferred to the oxydating flame becomes opaque. With salt of phosphorus (in the same proportion) in the inner flame gives a clear glass, and when reduced the glass is green; but in the outer becomes yellow. With a little more of assay the glass remains clear. With soda (12 parts to 1 of assay) dissolves; some clear portions are seen in the globule while hot, but on cooling opacity precedes the crystallization of the globule; finally a gray-brown slag remains, which, cooled from the outer flame, has a green color, indicating oxyd of manganese. Decomposed by much soda, and the resulting mass, heated with nitric acid, gives a heavy, white, insoluble powder, which with boiling water takes a white flocculent form; the powder exhibited all the characters of columbic acid (?). The acid solution, when mixed with carbonate of ammonia, remains clear; heated, some oxyd of iron falls, and the fluid is light yellow; with oxalic acid, a white earth separates, which, heated with sulphuric acid to destroy the oxalic acid, dissolves, and the fluid forms with potash, before complete neutralization, a white double salt, which has the characters of that from zirconia, but may also contain oxyd of cerium. The oxalate, when first formed, did not afford, when heated, the cinnamon-brown color characteristic of deutoxyd of cerium. The extremely small amount of the mineral under examination forbids the expression of certainty respecting the base. Although inclining to the opinion of the existence of cerium in the mineral, from the red color of the crystals, Mr. Hayes observes that he obtained no positive proof on this point.

834. ALURGITE. Alurgit *Breith.*, B. H. Ztg., xxiv. 336.

Massive, consisting of scales, rarely having an hexagonal outline. Cleavage: basal eminent, as in mica.

H.=2·25—3. G.=2·984—3. Lustre pearly to vitreous. Color purple to cochineal-red; in thinnest plates rose-red; streak rose-red. Transparent to translucent. Optically uniaxial.

Contains much manganese.

Occurs with manganese ores at St. Marcel in Piedmont.

Named from ἀλουργός, *purple*.

CATALOGUE OF AMERICAN LOCALITIES OF MINERALS.

The following catalogue may aid the mineralogical tourist in selecting his routes and arranging the plan of his journeys. Only important localities, affording cabinet specimens, are in general included; and the *names of those minerals which are obtainable in good specimens are distinguished by italics.* When a name is not italicized the mineral occurs only sparingly or of poor quality. When the specimens to be procured are remarkably good, an exclamation mark (!) is added, or two of these marks (! !) when the specimens are quite unique. The more exact position of localities may in most instances be ascertained by reference to the descriptions of the species in the preceding part of the Treatise.

For the facts included the country is especially indebted to the various Geological Reports of the several States, the American Journal of Science, and the Journals or Transactions of the different Scientific Societies or Academies. The author is under special obligations, in the preparation of the Catalogue for this edition of the Mineralogy, to W. W. Jefferis, Esq., of Westchester, Pa., Prof. C. U. Shepard, Prof. A. E. Verrill, Dr. J. S. Newberry, Prof. Wm. P. Blake, Prof. Wm. H. Brewer, Dr. F. A. Genth, Prof. B. Silliman, Prof. O. C. Marsh, Prof. A. Winchell, Dr. George Smith, of Upper Darby, Pa., Dr. T. R. Rand, of Philadelphia.

MAINE.

Albany.—*Beryl! green and black tourmaline, feldspar, rose quartz,* rutile.

Aroostook.—Red hematite.

Bath.—Idocrase, *garnet,* magnetite, graphite.

Bethel.—*Cinnamon garnet,* calcite, sphene, beryl, pyroxene. hornblende, epidote, graphite, talc, pyrite, mispickel, magnetite, wad.

Bingham.—*Massive pyrite.* galenite, blende, andalusite.

Blue Hill Bay.—*Arsenical iron, molybdenite! galenite, apatite! fluorite!* black tourmaline (Long Cove), black oxyd of manganese (Osgood's farm), rhodonite, bog manganese, wolframite.

Bowdoin.—*Rose Quartz.*

Bowdoinham.—*Beryl,* molybdenite.

Brunswick.—*Green mica, garnet! black tourmaline!* molybdenite, epidote, *calcite, muscovite, feldspar,* beryl.

Buckfield.—*Garnet* (estates of Waterman and Lowe), iron ore, *muscovite!* magnetite.

Camdage Farm.—(Near the Tide mills), molybdenite, wolframite.

Camden.—*Macle, galenite,* epidote, black tourmaline, pyrite, talc, magnetite.

Carmel (Penobscot Co.).—Stibnite, pyrite, macle.

Corinna.—*Pyrite, arsenical pyrites.*

Deer Isle —*Serpentine, verd-antique,* asbestus, diallage, magnetite.

Dexter.—Galenite, pyrite, blende, chalcopyrite, green talc.

Dixfield.—Native copperas, graphite.

Farmington.—(Norton's ledge), *pyrite,* graphite, bog ore, garnet, staurolite.

Freeport.—*Rose quartz, garnet,* feldspar, scapolite, graphite, *muscovite.*

Fryeburg.—*Garnet,* beryl.

Georgetown —(Parker's island), *beryl!* black tourmaline.

Greenwood.—Graphite, black manganese, *beryl! mispickel,* cassiterite, *mica, rose quartz, garnet* corundum, albite, zircon, molybdenite, magnetite, copperas.

Hebron.—*Cassiterite,* mispickel, idocrase, *lepidolite, amblygonite, rubellite!* indicolite, *green tourmaline, mica, beryl, apatite, albite, childrenite, cookeite.*

Jewell's Island.—Pyrite.

Katahdin Iron Works —Bog iron ore, pyrite, magnetite, quartz.

Letter E, Oxford Co.—Staurolite, macle, copperas.

Linnæus.—Hematite, limonite, *pyrite,* bog-iron ore.

Litchfield.—*Sodalite, cancrinite, elæolite, zircon,* spodumene, muscovite, pyrrhotite.

Lubec Lead Mines.—*Galenite, chalcopyrite, blende.*

Machiasport.—*Jasper*, epidote, laumontite.

Madawaska Settlements.—*Vivianite.*

Minot.—*Beryl, smoky quartz.*

Monmouth.—Actinolite, apatite, *elæolite, zircon*, staurolite, plumose mica, beryl, rutile.

Mt. Abraham.—*Andalusite*, staurolite.

Norway.—*Chrysoberyl!* molybdenite, *beryl, rose quartz, orthoclase*, cinnamon garnet.

Orr's Island.—*Steatite*, garnet, andalusite.

Oxford.—*Garnet, beryl*, apatite, wad, zircon, *muscovite.*

Paris.—*Green! red! black*, and *blue tourmaline! mica! lepidolite!* feldspar, *albite, quartz crystals! rose quartz, cassiterite, amblygonite*, zircon, brookite, beryl, smoky quartz, spodumene, *cookeite*, leucopyrite.

Parsonsfield.—*Idocrase! yellow garnet, pargasite, adularia, scapolite*, galenite, blende, chalcopyrite.

Peru.—*Crystallized pyrite.*

Phipsburg.—*Yellow garnet! manganesian garnet, idocrase, pargasite, axinite, laumontite!* chabazite, an ore of cerium?

Poland.—Idocrase, smoky quartz, cinnamon garnet.

Portland.—*Prehnite*, actinolite, garnet, epidote, amethyst, calcite.

Pownal.—*Black tourmaline, feldspar*, scapolite, pyrite, actinolite, apatite, rose quartz.

Raymond.—*Magnetite, scapolite, pyroxene, lepidolite, tremolite*, hornblende, epidote, orthoclase, yellow garnet, pyrite, idocrase.

Rockland.—Hematite, tremolite, *quartz*, wad, *talc.*

Rumford.—*Yellow garnet, idocrase, pyroxene*, apatite, scapolite, graphite.

Rutland.—Allanite.

Sandy River.—Auriferous sand.

Sanford, York Co.—*Idocrase!* albite, calcite, molybdenite, epidote, black tourmaline.

Searsmont.—*Andalusite*, tourmaline.

South Berwick.—Macle.

Streaked Mountain.—*Beryl! black tourmaline, mica, garnet.*

Thomaston.—*Calcite, tremolite, hornblende*, sphene, arsenical iron (Owl's head), black manganese (Dodge's mountain), *thomsonite, talc*, blende, pyrite, galenite.

Topsham.—*Quartz*, galenite, blende, tungstite? beryl, apatite, molybdenite.

Union.—Magnetite, bog-iron ore.

Wales.—Axinite in boulder, alum, copperas.

Waterville.—*Crystallized pyrite.*

Windham (near the bridge).—*Staurolite, spodumene, garnet*, beryl, amethyst, *cyanite*, tourmaline.

Winthrop.—*Staurolite*, pyrite, hornblende, garnet, copperas.

Woodstock.—*Graphite, specular iron*, prehnite, epidote, calcite.

York.—*Beryl*, vivianite, oxyd of manganese.

NEW HAMPSHIRE.

Acworth.—*Beryl!! mica! tourmaline, feldspar, albite, rose quartz, columbite!*

Alstead.—*Mica!! albite, black tourmaline.*

Amherst.—*Idocrase! yellow garnet*, pargasite, calc spar.

Bartlett.—Magnetite, *specular iron*, brown iron ore in large veins near Jackson (on "Bald face mountain"), *quartz crystals, smoky quartz.*

Bath.—Galenite, chalcopyrite.

Bellows Falls.—Cyanite.

Benton.—*Quartz crystals.*

Campton.—*Beryl!*

Canaan.—Gold in pyrites.

Charlestown.—*Staurolite macle, andalusite macle*, bog-iron ore.

Cornish.—Stibnite, tetrahedrite, *rutile in quartz!* (rare).

Croyden.—*Iolite!*

Eaton (3 m. S. of).—*Galenite, blende!* chalcopyrite, limonite (Six Mile Pond).

Franceston.—*Soapstone*, arsenical pyrites.

Franconia.—*Hornblende, staurolite! epidote! zoisite, specular iron, magnetite, black* and *red manganesian garnets, mispickel!* (*danaite*), chalcopyrite, molybdenite, prehnite.

Gilford (Gunstock Mt.).—Magnetic iron ore, native "lodestone."

Goshen.—*Graphite*, black tourmaline.

GRAFTON.—*Mica!* (extensively quarried at Glass Hill, 2 m. S. of Orange Summit), *albite!* blue, green, and yellow *beryls!* (1 m. S. of O. Summit), *tourmaline*, *garnets*.

GRANTHAM.—*Gray staurolite!*

HANOVER.—*Garnet*, a boulder of quartz containing *rutile! black tourmaline*, *quartz*.

HAVERHILL.—*Garnet! arsenical pyrites*, *native arsenic*, galenite, blende, iron and copper pyrites magnetic and white iron pyrites.

HILLSBORO' (Campbell's mountain).—*Graphite.*

HILLSDALE.—*Rhodonite*, black oxyd of manganese.

JACKSON.—Drusy quartz, tin ore, *arsenopyrite*, native arsenic, fluorite, apatite, *magnetite*, *molybdenite*, wolfram, chalcopyrite, arsenate of iron.

JAFFREY (Monadnock Mt.).—*Cyanite.*

KEENE.—*Graphite*, *soapstone*, milky quartz.

LANDAFF.—*Molybdenite*, lead and iron ores.

LEBANON.—*Bog-iron ore.*

LISBON.—*Staurolite*, black and red *garnets*, *granular magnetite*, *hornblende*, *epidote*, *zoisite*, *specular iron.*

LYME.—Cyanite (N.W. part), *black tourmaline*, rutile, pyrite, chalcopyrite (E. of E. village), *stibnite.*

MERRIMACK.—*Rutile!* (in gneiss nodules in granite vein).

MOULTONBOROUGH (Red Hill).—*Hornblende*, bog ore, pyrite, tourmaline.

NEWPORT.—Molybdenite.

ORANGE.—*Blue beryls!* Orange Summit, chrysoberyl, *mica* (W. side of mountain).

ORFORD.—*Brown tourmaline* (now obtained with difficulty), *steatite*, *rutile*, cyanite, brown iron ore, native copper, malachite, galenite.

PELHAM.—*Steatite.*

PIERMONT.—*Micaceous iron*, barite, green, white, and brown mica, apatite.

PLYMOUTH.—Columbite, beryl.

RICHMOND.—*Iolite!* rutile, steatite, pyrite.

RYE.—Macle.

SADDLEBACK MT.—Black tourmaline, garnet, spinel.

SHELBURNE.—*Galenite*, *black blende*, *chalcopyrite*, *pyrite*, manganese.

SPRINGFIELD.—Beryls (very large, eight inches diameter), *manganesian garnets!* in mica slate, *albite*, *mica.*

SULLIVAN.—*Tourmalines* (black), in quartz, beryl?

SURREY.—Amethyst, calcite.

SWANZEY (near Keene).—*Magnetic iron* (in masses in granite).

TAMWORTH (near White Pond).—Galenite.

UNITY (estate of James Neal).—*Copper and iron pyrites*, *chlorophyllite*, *green mica*, *radiated actinolite*, garnet, *titaniferous iron ore*, *magnetite.*

WALPOLE (near Bellows Falls).—Macle.

WARREN.—*Chalcopyrite*, *blende*, *epidote*, quartz, *pyrite*, *tremolite*, *galenite*, *rutile*, *talc*, molybdenite, *cinnamon stone! pyroxene.*

WESTMORELAND (south part).—*Molybdenite! apatite! blue feldspar*, *bog manganese* (north village), quartz, *fluorite*, chalcopyrite, oxyd of molybdenum and uranium.

WHITE MTS. (notch behind "old Crawford's house").—Green octahedral fluor, quartz crystals, black tourmaline, chiastolite.

WILMOT.—*Beryl.*

WINCHESTER.—Pyrolusite, rhodochrosite, psilomelane, magnetite, granular quartz.

VERMONT.

ADDISON.—*Iron sand*, pyrite.

ALBURGH.—Quartz crystals on calcite, pyrite.

ATHENS.—*Steatite*, *rhomb spar*, actinolite, garnet.

BALTIMORE.—*Serpentine*, *pyrites!*

BARNET.—Graphite.

BELVIDERE.—Steatite, chlorite.

BENNINGTON.—*Pyrolusite*, brown iron ore, pipe clay, yellow ochre.

BERKSHIRE.—*Epidote*, hematite, magnetite.

BETHEL.—*Actinolite!* talc, chlorite, octahedral iron, *rutile*, *brown spar in steatite.*

BRANDON.—Braunite, pyrolusite, *psilomelane*, limonite, lignite, white clay, statuary marble fossil fruits in the lignite, graphite, chalcopyrite.

BRATTLEBOROUGH.—Black tourmaline in quartz, mica, zoisite, rutile, actinolite, scapolite, spodumene, roofing slate.

BRIDGEWATER.—*Talc*, *dolomite*, *magnetite*, steatite, chlorite, gold, native copper, blende, galenite blue spinel, chalcopyrite.

BRISTOL.—*Rutile*, brown hematite, manganese ores, magnetite.

BROOKFIELD.—*Mispickel*, *pyrite*.

CABOT.—Garnet, staurolite, hornblende, *albite*.

CASTLETON.—*Roofing slate*, jasper, manganese ores, chlorite.

CAVENDISH.—Garnet, *serpentine*, *talc*, *steatite*, *tourmaline*, *asbestus*, *tremolite*.

CHESTER.—*Asbestus*, feldspar, chlorite, *quartz*.

CHITTENDEN.—Psilomelane, pyrolusite, brown iron ore, *specular* and *magnetic iron*, galenite, iolite.

COLCHESTER.—Brown iron ore, iron sand, jasper, alum.

CORINTH.—*Copper pyrites* (has been mined), pyrrhotite, pyrite, rutile, quartz.

COVENTRY.—Rhodonite.

CRAFTSBURY.—Mica in concentric balls, calcite, rutile.

DERBY.—Mica (*adamsite*).

DUMMERSTON.—Rutile, roofing slate.

FAIRHAVEN.—*Roofing slate*, pyrite.

FLETCHER.—Pyrite, octahedral iron, acicular tourmaline.

GRAFTON.—The *steatite* quarry referred to Grafton is properly in Athens; *quartz*, actinolite.

GUILFORD.—Scapolite, rutile, roofing slate.

HARTFORD.—Calcite, *pyrite!* *cyanite* in mica slate, quartz, tourmaline.

IRASBURGH.—Rhodonite, *psilomelane*.

JAY.—*Chromic iron*, *serpentine*, amianthus, dolomite.

LOWELL.—Picrosmine, amianthus, serpentine, cerolite, talc, chlorite.

MARLBORO'.—*Rhomb spar*, *steatite*, *garnet*, *magnetite*, chlorite.

MENDON.—Octahedral iron ore.

MIDDLEBURY.—Zircon.

MIDDLESEX.—Rutile! (exhausted).

MONKTON.—*Pyrolusite*, brown iron ore, pipe clay, feldspar.

MORETOWN.—*Smoky quartz!* *steatite*, talc, wad, rutile, serpentine.

MORRISTOWN.—Galenite.

MOUNT HOLLY.—*Asbestus*, chlorite.

NEW FANE.—*Glassy* and *asbestiform actinolite*, *steatite*, *green quartz* (called chrysoprase at the locality), chalcedony, drusy quartz, *garnet*, *chromic and titanic iron*, *rhomb spar*, serpentine, rutile.

NORWICH.—*Actinolite*, *feldspar*, *brown spar* in talc, cyanite, zoisite, chalcopyrite, pyrite.

PITTSFORD.—*Brown iron ore*, manganese ores.

PLYMOUTH.—Spathic iron, magnetic and specular iron, both in octahedral crystals, *gold*, galenite.

PLYMPTON.—Massive hornblende.

PUTNEY.—Fluorite, *brown iron ore*, *rutile*, and *zoisite*, in boulders, staurolite.

READING.—*Glassy actinolite* in talc.

READSBORO'.—*Glassy actinolite*, *steatite*, hematite.

RIPTON.—*Brown iron ore*, augite in boulders, octahedral pyrite.

ROCHESTER.—Rutile, specular iron cryst., *magnetite* in chlorite slate.

ROCKINGHAM (Bellows Falls).—Cyanite, indicolite, feldspar, tourmaline, fluorite, calcite, prehnite staurolite.

ROXBURY.—*Dolomite*, *talc*, serpentine, asbestus, quartz.

RUTLAND.—*Magnesite*, *white marble*, hematite, serpentine, pipe clay.

SALISBURY.—Brown iron ore.

SHARON.—*Quartz crystals*, cyanite.

SHOREHAM.—*Pyrite*, black marble, calcite.

SHREWSBURY.—Magnetite and chalcopyrite.

STARKSBORO'.—Brown iron ore.

STIRLING.—Chalcopyrite, talc, serpentine.

STOCKBRIDGE.—Mispickel, magnetic iron ore.

STRAFFORD.—Magnetite and *chalcopyrite* (has been worked), native copper, hornblende, copperas.

THETFORD.—Blende, *galenite*, *cyanite*; chrysolite in basalt, pyrrhotite, *feldspar*, *roofing slate*, steatite, garnet.

TOWNSHEND.—*Actinolite*, black mica, *talc*, steatite, feldspar.

TROY.—*Magnetite*, talc, *serpentine*, picrosmine, amianthus, *steatite*, one mile southeast of village of South Troy, on the farm of Mr. Pierce, east side of Missisco, *chromic iron*, saratite.

VERSHIRE.—*Pyrite*, chalcopyrite, tourmaline, mispickel, quartz.

Wardsboro'.—*Zoisite*, tourmaline, *tremolite*, hematite.
Warren.—Actinolite, magnetite, wad, serpentine.
Waterbury.—Mispickel, chalcopyrite, *rutile*, *quartz*, serpentine.
Waterville.—*Steatite*, actinolite, talc.
Weathersfield.—*Steatite*, *specular iron*, *pyrite*, tremolite.
Wells' River.—Graphite.
Westfield.—*Steatite*, chromic iron, serpentine.
Westminster.—Zoisite in boulders.
Windham.—*Glassy actinolite*, *steatite*, *garnet*, serpentine.
Woodbury.—Massive pyrite.
Woodstock.—*Quartz crystals*, garnet, zoisite.

MASSACHUSETTS.

Alford.—Galenite, pyrite.

Athol.—*Allanite*, fibrolite, (?) *epidote!* babingtonite?

Auburn.—*Masonite*.

Barre.—*Rutile! mica*, *pyrite*, *beryl*, *feldspar*, *garnet*.

Great Barrington.—*Tremolite*.

Bedford.—*Garnet*.

Belchertown.—Allanite.

Bernardston.—Magnetite.

Beverly.—Columbite, *green feldspar*, cassiterite.

Blanford.—*Serpentine*, *anthophyllite*, *actinolite! chromite*, cyanite, rose quartz in boulders.

Bolton.—*Scapolite! petalite*, *sphene*, *pyroxene*, *nuttalite*, *diopside*, *boltonite*, apatite, magnesite, rhomb spar, *allanite*, *yttrocerite?* cerium ochre? (on the scapolite), spinel.

Boxborough.—*Scapolite*, spinel, *garnet*, augite, actinolite, apatite.

Brighton.—Asbestus.

Brimfield (road leading to Warren).—*Iolite*, adularia, molybdenite, mica, garnet.

Carlisle.—*Tourmaline*, *garnet! scapolite*, actinolite.

Charlestown.—*Prehnite*, *laumontite*, stilbite, chabazite, quartz crystals, melanolite.

Chelmsford.—*Scapolite* (chelmsfordite), *chondrodite*, *blue spinel*, *amianthus!* rose quartz.

Chester.—*Hornblende*, *scapolite*, *zoisite*, *spodumene*, *indicolite*, apatite, magnetite, chromite, stilbite, heulandite, analcite and chabazite: at the Emery Mine, Chester Factories.—*Corundum*, *margarite*, *diaspore*, epidote, corundophilite, chloritoid, tourmaline, *menaccanite!* rutile, biotite, indianite? andesite? *cyanite*.

Chesterfield.—*Blue*, *green*, *and red tourmaline*, *cleavelandite* (albite), *lithia mica*, *smoky quartz*, *microlite*, *spodumene*, *cyanite*, apatite, *rose beryl*, *garnet*, *quartz crystals*, *staurolite*, cassiterite, *columbite*, zoisite, uranite, brookite (eumanite), scheelite, anthophyllite, bornite.

Conway.—Pyrolusite, fluorite, zoisite, *rutile!!* native alum, galenite.

Cummington.—*Rhodonite!* cummingtonite (hornblende), marcasite, *garnet*.

Dedham.—Asbestus, galenite.

Deerfield.—Chabazite, heulandite, stilbite, amethyst, carnelian, chalcedony, *agate*.

Fitchburg (Pearl Hill).—*Beryl*, *staurolite!* garnets, molybdenite.

Foxborough.—*Pyrite*, *anthracite*.

Franklin.—Amethyst.

Goshen.—*Mica*, *albite*, *spodumene! blue and green tourmaline*, *beryl*, *zoisite*, smoky quartz, columbite, tin ore, galenite, beryl (goshenite), pihlite (cymatolite).

Greenfield (in sandstone quarry, half mile east of village).—Allophane, white and greenish.

Hatfield.—Barite, yellow quartz crystals, galenite, blende, chalcopyrite.

Hawley.—*Micaceous iron*, massive pyrite, magnetite, zoisite.

Heath.—*Pyrite*, *zoisite*.

Hinsdale.—Brown iron ore, apatite, zoisite.

Hubbardston.—*Massive pyrite*.

Lancaster.—*Cyanite*, *chiastolite!* apatite, staurolite, pinite, andalusite.

Lee.—*Tremolite! sphene!* (east part).

Lenox.—Brown hematite, gibbsite (?).

Leverett.—Barite, galenite, blende, chalcopyrite.

Leyden.—*Zoisite*, *rutile*.

Littleton.—Spinel, scapolite, apatite.

Lynnfield.—Magnesite on serpentine.

Martha's Vineyard.—Brown iron ore, amber, selenite, radiated pyrite.

Mendon.—*Mica!* chlorite.

Middlefield.—*Glassy actinolite, rhomb spar, steatite, serpentine, feldspar*, drusy quartz, apatite, zoisite, nacrite, chalcedony, *talc!* deweylite.

Milbury.—*Vermiculite.*

Montague.—Specular iron.

Newbury.—*Serpentine*, chrysotile, *epidote, massive garnet*, siderite.

Newburyport.—*Serpentine, nemalite*, uranite.

New Braintree.—*Black tourmaline.*

Norwich.—*Apatite! black tourmaline, beryl, spodumene! triphyline* (altered), blende, quartz crystals, cassiterite.

Northfield.—*Columbite*, fibrolite, cyanite.

Palmer (Three Rivers).—*Feldspar*, prehnite, calc spar.

Pelham.—*Asbestus*, serpentine, *quartz crystals*, beryl, *molybdenite, green hornstone*, epidote, amethyst.

Plainfield.—*Cummingtonite, pyrolusite, rhodonite.*

Richmond.—*Brown iron ore, gibbsite! allophane.*

Rockport.—*Danalite, cryophyllite, annite, cyrtolite* (altered zircon), *green* and *white orthoclase.*

Rowe.—Epidote, talc.

South Royalston.—*Beryl!!* (now obtained with great difficulty), *mica!! feldspar!* allanite Four miles beyond old loc., on farm of Solomon Heywood, *mica! beryl! feldspar!* menaccanite.

Russel.—Schiller spar (diallage?), *mica*, serpentine, beryl, galenite, chalcopyrite.

Salem.—In a boulder, cancrinite, sodalite, elæolite.

Saugus.—Porphyry, jasper.

Sheffield.—*Asbestus*, pyrite, native alum, pyrolusite.

Shelburne.—Rutile.

Shutesbury (east of Locke's Pond).—*Molybdenite.*

Southampton.—*Galenite*, cerussite, anglesite, *wulfenite*, fluorite, barite, copper and iron pyrites, blende, corneous lead, pyromorphite, stolzite, chrysocolla.

Sterling.—*Spodumene, chiastolite, spathic iron, mispickel, blende*, galenite, chalcopyrite, pyrite.

Stoneham.—*Nephrite.*

Sturbridge.—*Graphite*, garnet, apatite, bog ore.

Swampscot.—*Orthite*, feldspar.

Taunton (one mile south).—Paracolumbite (titanic iron).

Turner's Falls (Conn. River).—Chalcopyrite, prehnite, chlorite, *chlorophæite*, spathic iron, malachite, magnetic iron sand, anthracite.

Tyringham.—Pyroxene, scapolite.

Uxbridge.—Galenite.

Warwick.—*Massive garnet, radiated black tourmaline, magnetite*, beryl, epidote.

Washington.—*Graphite.*

Westfield.—*Schiller spar* (diallage), *serpentine, steatite*, cyanite, scapolite, actinolite.

Westford.—*Andalusite!*

West Hampton.—Galenite, *argentine, pseudomorphous quartz.*

West Springfield.—*Prehnite*, ankerite, satin spar, celestite, bituminous coal.

West Stockbridge.—*Hematite*, fibrous pyrolusite, spathic iron.

Whately.—*Native copper*, galenite.

Williamsburg.—*Zoisite*, pseudomorphous quartz, apatite, rose and smoky quartz, galenite, pyrolusite, chalcopyrite.

Williamstown.—*Cryst. quartz.*

Windsor.—*Zoisite*, actinolite, *rutile!*

Worcester.—*Mispickel*, idocrase, pyroxene, garnet, amianthus, bucholzite, spathic iron, galenite.

Worthington.—*Cyanite.*

Zoar.—Bitter spar. *talc.*

RHODE ISLAND.

Bristol.—*Amethyst.*

Cranston.—Actinolite in talc.

Cumberland.—*Manganese, epidote, actinolite*, garnet, titaniferous iron, magnetite, red hematite chalcopyrite.

Foster.—*Cyanite.*

Gloucester.—*Magnetite* in chlorite slate.

Johnson.—Talc, brown spar.

Natic.—See Warwick.

Newport.—*Serpentine.*

Portsmouth.—*Anthracite*, graphite, asbestus, pyrite.

SMITHFIELD.—*Dolomite*, *calcite*, *bitter spar*, *nacrite*, serpentine (bowenite), tremolite, asbestus, quartz, magnetic iron in chlorite slate, *talc!* anatase.

WARWICK (Natic village).—*Masonite*, garnet, graphite.

WESTERLY.—*Ilmenite*.

CONNECTICUT.

BERLIN.—Barite, datolite, blende, quartz crystals.

BOLTON.—Staurolite, chalcopyrite.

BRADLEYVILLE (Litchfield).—Laumontite.

BRISTOL.—*Chalcocite! chalcopyrite*, barite, *bornite*, talc, *allophane*, pyromorphite, *calcite*, malachite, galenite, quartz.

BROOKFIELD.—Galenite, calamine, *blende*, spodumene, pyrrhotite.

CANAAN.—*Tremolite* and white *augite!* in dolomite, canaanite (massive pyroxene).

CHATHAM.—Mispickel, smaltite, chloanthite (chathamite), scorodite, niccolite, *beryl*, erythrite.

CHESHIRE.—*Barite*, *chalcocite*, *bornite cryst.*, *malachite*, kaolin, natrolite, prehnite, chabazite, datolite.

CHESTER.—*Sillimanite!* zircon, epidote.

CORNWALL.—*Graphite*, *pyroxene*, *actinolite*, *sphene*, scapolite.

DANBURY.—*Danburite*, *oligoclase*, *moonstone*, brown tourmaline, orthoclase, pyroxene, parathorite.

FARMINGTON.—*Prehnite*, *chabazite*, agate, native copper.

GRANBY.—Green malachite.

GREENWICH.—*Black tourmaline*.

HADDAM.—*Chrysoberyl! beryl! epidote! tourmaline! feldspar*, *garnet! iolite! oligoclase*, *chlorophyllite! automolite*, *magnetite*, *adularia*, apatite, *columbite!* zircon (calyptolite), *mica*, pyrite, marcasite, *molybdenite*, allanite, bismuth, bismuth ochre, bismutite.

HADLYME.—Chabazite and stilbite in gneiss, with epidote and garnet.

HARTFORD.—*Datolite* (Rocky Hill quarry).

KENT.—*Brown iron ore*, pyrolusite, ochrey iron ore.

LITCHFIELD.—*Cyanite* with corundum, apatite, and andalusite, *menaccanite* (washingtonite), chalcopyrite, diaspore, niccoliferous pyrrhotite, margarodite.

LYME.—Garnet, sunstone.

MERIDEN.—Datolite.

MIDDLEFIELD FALLS.—Datolite, chlorite, etc., in amygdaloid.

MIDDLETOWN.—*Mica*, *lepidolite* with green and red tourmaline, *albite*, *feldspar*, *columbite! prehnite*, *garnet* (sometimes octahedral), beryl, topaz, uranite, apatite, pitchblende; at lead mine, *galenite*, *chalcopyrite*, blende, quartz, *calcite*, fluorite, pyrite, sometimes capillary.

MILFORD.—Sahlite, *pyroxene*, *asbestus*, zoisite, verd-antique marble, pyrite.

NEW HAVEN.—Serpentine, asbestus, chromic iron, sahlite, stilbite, prehnite.

NORWICH.—*Sillimanite*, *monazite!* zircon, *iolite*, corundum, feldspar.

OXFORD, near Humphreysville.—Cyanite, chalcopyrite.

PLYMOUTH.—Galenite, *heulandite*, *fluorite*, *chlorophyllite!* garnet.

ROARING BROOK (Cheshire).—*Datolite!* calcite, prehnite, saponite.

READING (near the line of Danbury).—Pyroxene, *garnet*.

ROXBURY.—*Spathic iron*, *blende*, *pyrite! ! galenite*, quartz, chalcopyrite.

SALISBURY.—*Brown iron ore*, ochrey iron, *pyrolusite*, triplite, *turgite*.

SAYBROOK.—*Molybdenite*, stilbite, plumbago.

SIMSBURY.—*Copper glance*, green malachite.

SOUTHBURY.—Rose quartz, laumontite, prehnite, calc spar, heavy spar.

SOUTHINGTON.—Heavy spar, datolite, asteriated quartz crystals.

STAFFORD.—Massive pyrites, alum, copperas.

STONINGTON.—Stilbite and *chabazite* on gneiss.

THATCHERSVILLE (near Bridgeport).—Stilbite on gneiss, babbingtonite?

TOLLAND.—Staurolite, massive pyrites.

TRUMBULL and MONROE.—*Chlorophane*, *topaz*, *beryl*, diaspore, pyrrhotite, pyrite, scheelite, *wolframite* (pseudomorph of scheelite), rutile, native bismuth, tungstic acid, spathic iron, mispickel, argentiferous galenite, blende, scapolite, *tourmaline*, *garnet*, albite, augite, graphic tellurium, (?) *margarodite*.

WASHINGTON.—*Triplite*, *menaccanite!* (washingtonite of Shepard), rhodochrosite, natrolite, *andalusite* (New Preston), cyanite.

WATERTOWN, near the Naugatuck.—White sahlite, monazite.

WEST FARMS.—Asbestus.

WILLIMANTIC.—*Topaz, monazite, ripidolite.*
WINCHESTER and WILTON.—Asbestus, garnet.

NEW YORK.

ALBANY CO.—BETHLEHEM.—Calcite, stalactite, stalagmite, calcareous sinter, snowy gypsum.

COEYMAN'S LANDING.—Gypsum, epsom salt, *quartz* crystals at Crystal Hill, three miles south of Albany.

GUILDERLAND.—Petroleum, anthracite, and calcite, on the banks of the Norman's Kill, two miles south of Albany.

WATERVLIET.—*Quartz crystals*, yellow drusy quartz.

ALLEGHANY CO.—CUBA.—Calcareous tufa, petroleum, 3½ miles from the village.

CATTARAUGUS CO.—FREEDOM.—*Petroleum.*

CAYUGA CO.—AUBURN.—Celestite, calcite, fluor spar, epsomite.
CAYUGA LAKE.—Sulphur.
LUDLOWVILLE.—Epsomite.
UNION SPRINGS.—*Selenite*, gypsum.
SPRINGPORT.—At Thompson's plaster beds, *sulphur ! selenite.*
SPRINGVILLE.—Nitrogen springs.

CLINTON CO.—ARNOLD IRON MINE.—*Magnetite*, epidote, molybdenite.
FINCH ORE BED.—*Calcite, green* and purple fluor.

CHATAUQUE CO.—FREDONIA.—*Petroleum, carburetted hydrogen.*
LAONA.—Petroleum.
SHERIDAN.—Alum.

COLUMBIA CO.—AUSTERLITZ.—*Earthy manganese*, wulfenite, chalcocite; Livingston lead mine, vitreous silver?

CHATHAM.—Quartz, pyrite in cubic crystals in slate (Hillsdale).

CANAAN.—Chalcocite, chalcopyrite.

HUDSON.—Epidote, *selenite !*

NEW LEBANON.—Nitrogen springs, graphite, anthracite; at the Ancram lead mine, galenite, barite, *blende, wulfenite* (rare), chalcopyrite, calcareous tufa; near the city of Hudson, epsom salt, brown spar, *wad.*

DUTCHESS CO.—AMENIA.—Dolomite, *limonite, turgite.*

BECKMAN.—*Dolomite.*

DOVER.—Dolomite, tremolite, *garnet* (Foss ore bed), staurolite, *limonite.*

FISHKILL.—Dolomite; near Peckville, talc, asbestus, *graphite, hornblende*, augite, *actinolite*, hydrous anthophyllite, *limonite.*

NORTH EAST.—Chalcocite, chalcopyrite, galenite, blende.

PAWLING.—Dolomite.

RHINEBECK.—Calcite, green feldspar, epidote, tourmaline.

UNION VALE.—At the Clove mine, *gibbsite, limonite.*

ESSEX CO.—ALEXANDRIA.—Kirby's graphite mine, *graphite, pyroxene, scapolite*, sphene.

CROWN POINT.—*Apatite* (eupyrchroite of *Emmons*), *brown tourmaline !* in the apatite, chlorite, quartz crystals, pink and blue calcite, pyrite; a short distance south of J. C. Hammond's house, *garnet, scapolite*, chalcopyrite, *aventurine feldspar*, zircon, magnetic iron (Peru), epidote, mica.

KEENE.—Scapolite.

LEWIS.—*Tabular spar, colophonite*, garnet, *labradorite, hornblende*, actinolite; ten miles south of the village of Keeseville, mispickel.

LONG POND.—Apatite, *garnet, pyroxene*, idocrase, *coccolite ! ! scapolite*, magnetite, *blue calcite.*

MCINTYRE.—*Labradorite*, garnet, *magnetite.*

MORIAH, at Sandford Ore Bed.—*Magnetite*, apatite, *allanite !* lanthanite, actinolite, and feldspar; at Fisher Ore Bed, *magnetic iron*, feldspar, quartz; at Hall Ore Bed, or "New Ore Bed," *magnetite, zircons;* on Mill brook, *calcite*, pyroxene, hornblende, albite; in the town of Moriah, magnetite, *black mica.*

Newcomb.—*Labradorite*, feldspar, magnetic iron, hypersthene.

Port Henry.—*Brown tourmaline*, *mica*, *rose quartz*, *serpentine*, *green* and *black pyroxene*, hornblende, *cryst. pyrite*, graphite, tabular spar, pyrrhotine, *adularia*; *phlogopite!* at Cheever Ore Bed with magnetite and serpentine.

Roger's Rock.—*Graphite*, *tabular spar*, *garnet*, *colophonite*, *feldspar*, adularia, *pyroxene*, *sphene* coccolite.

Schroon.—*Calcite*, pyroxene, *chondrodite*.

Ticonderoga.—*Graphite! pyroxene*, *sahlite*, *sphene*, black tourmaline, cacoxene ? (Mt. Defiance).

Westport.—Labradorite, prehnite, magnetite.

Willsboro'.—*Tabular spar*, *colophonite*, garnet, *green coccolite*, hornblende.

ERIE CO.—Ellicott's Mills.—*Calcareous tufas.*

FRANKLIN CO.—Chateaugay.—Nitrogen springs, calcareous tufas.

Malone.—*Massive pyrite*, magnetic iron ore.

GENESEE CO.—*Acid springs* containing sulphuric acid.

GREENE CO.—Catskill.—*Calcite.*

Diamond Hill.—Quartz crystals.

HERKIMER CO.—Fairfield.—*Quartz crystals*, fetid barite.

Little Falls.—*Quartz crystals!* barite, calcite, anthracite, pearl spar, *smoky quartz*; one mile south of Little Falls, calcite, brown spar, feldspar.

Middleville.—*Quartz crystals! calcite*, brown and pearl spar, anthracite.

Newport.—*Quartz crystals.*

Salisbury.—*Quartz crystals!* blende, galenite, iron and copper pyrites.

Stark.—Fibrous celestite, *gypsum*.

HAMILTON CO.—Long Lake.—Blue calcite.

JEFFERSON CO.—Adams.—Fluor, calc tufa, barite.

Alexandria.—On the S.E. bank of Muscolonge Lake, fluorite, *phlogopite*, chalcopyrite; on High Island, in the St. Lawrence River, feldspar, *tourmaline*, hornblende, *orthoclase*, celestite.

Antwerp.—Stirling iron mine, *specular iron*, *chalcodite*, *spathic iron*, *millerite*, *red hematite*, crystallized quartz, *yellow aragonite*, niccoliferous iron pyrites, *quartz crystals*, pyrite; at Oxbow, *calcite!* porous coralloidal heavy spar; near Vrooman's lake, *calcite!* idocrase, *phlogopite! pyroxene*, *sphene*, fluorite, pyrite, chalcopyrite; also *feldspar*, *bog-iron ore*, scapolite (farm of David Eggleson), *serpentine*, tourmaline (yellow, rare).

Brownsville.—Celestite in slender crystals, calcite (four miles from Watertown).

Natural Bridge.—Feldspar, *gieseckite! steatite*, *pseudomorphous* after pyroxene.

New Connecticut.—*Sphene*, *brown phlogopite.*

Omar.—*Beryl*, *feldspar*, *specular iron.*

Philadelphia.—*Garnets* on Indian river, in the village.

Pamelia.—*Agaric mineral*, calc tufa.

Pillar Point.—*Massive heavy spar* (exhausted).

Theresa.—*Fluor*, *calcite*, specular iron ore, hornblende, *quartz crystals*, serpentine (associated with the specular iron), celestite, strontianite; the Muscolonge Lake locality of fluor is exhausted.

Watertown.—*Tremolite*, *agaric mineral*, calc tufa, celestite.

Wilna.—One mile north of Natural Bridge, *calcite.*

LEWIS CO.—Diana (localities mostly near junction of crystalline and sedimentary rocks, and within two miles of Natural Bridge).—*Scapolite! tabular spar*, *green coccolite*, *feldspar*, *tremolite*, *pyroxene! sphene!!* mica, *quartz crystals*, drusy quartz, cryst. pyrite, pyrrhotite, *blue calcite*, serpentine, *rensselaerite*, zircon, graphite, chlorite, specular iron, bog-iron ore, iron sand, *apatite.*

Greig.—*Magnetite*, pyrite.

Lowville.—*Calcite*, fluorite, pyrite, galenite, blende, calc tufa.

Martinsburgh.—Wad, galenite, etc., but mine not now opened, *calcite.*

Watson, Bremen.—Bog-iron ore.

MONROE CO.—Rochester.—*Pearl spar*, calc spar, snowy gypsum, fluor, celestite, galenite blende, barite, hornstone.

MONTGOMERY CO.—Canajoharie.—Anthracite.

Palatine.—*Quartz crystals*, drusy quartz, anthracite, hornstone, agate, garnet.

Root.—Pearl spar, *drusy quartz*, *blende*, barite, stalactite, stalagmite, galenite, pyrite.

NEW YORK CO.—Corlear's Hook.—Apatite, brown and yellow feldspar, sphene

Kingsbridge.—*Tremolite*, *pyroxene*, *mica*, *tourmaline*, pyrites, rutile, dolomite.

Harlem.—Epidote, apophyllite, stilbite, tourmaline, vivianite, lamellar feldspar, mica.

New York.—*Serpentine*, *amianthus*, actinolite, *pyroxene*, hydrous anthophyllite, garnet, staurolite, molybdenite, graphite, *chlorite*, jasper, *necronite*, feldspar.

NIAGARA CO.—Lewiston.—*Epsomite.*

Lockport.—*Celestite*, *calcite*, *selenite*, *anhydrite*, *fluorite*, dolomite, *blende.*

Niagara Falls.—*Calcite*, fluorite, blende, *dolomite.*

ONEIDA CO.—Boonville.—*Calcite*, *tabular spar*, *coccolite.*

Clinton.—*Blende*, *lenticular argillaceous iron ore;* in rocks of the Clinton Group, strontianite, celestite, the former covering the latter.

ONONDAGA CO.—Camillus.—*Selenite* and *fibrous gypsum.*

Cold Spring.—Axinite.

Manlius.—*Gypsum* and fluor.

Syracuse.—*Serpentine*, celestite, selenite, barite.

ORANGE CO.—Cornwall.—*Zircon*, *chondrodite*, *hornblende*, *spinel*, *massive feldspar*, *fibrous epidote*, hudsonite, menaccanite, *serpentine*, coccolite.

Deer Park.—*Cryst. pyrite*, galenite.

Monroe.—*Mica! sphene! garnet*, colophonite, *epidote*, *chondrodite*, *allanite*, bucholzite, brown spar, *spinel*, hornblende, talc, menaccanite, *pyrrhotite*, pyrite, chromic iron, *graphite*, rastolyte, moronolite.

At Wilks and O'Neil Mine in Monroe.—Aragonite, *magnetite*, dimagnetite (pseud.?), jenkinsite, *asbestus*, serpentine, *mica.*

At Two Ponds in Monroe.—*Pyroxene! chondrodite*, *hornblende*, *scapolite! zircon*, *sphene*, apatite.

At Greenwood Furnace in Monroe.—*Chondrodite*, *pyroxene! mica*, *hornblende*, *spinel*, *scapolite*, *biotite!* menaccanite.

At Forest of Dean.—*Pyroxene*, *spinel*, zircon, scapolite, hornblende.

Town of Warwick, Warwick Village.—*Spinel! zircon*, *serpentine! brown spar*, *pyroxene! hornblende! pseudomorphous steatite*, *feldspar!* (Rock Hill), menaccanite, *clintonite*, tourmaline (R. H.), *rutile*, *sphene*, molybdenite, mispickel, marcasite, pyrite, yellow iron sinter, quartz, jasper, mica, coccolite.

Amity.—*Spinel! garnet*, *scapolite*, *hornblende*, *idocrase*, *epidote! clintonite! magnetite*, *tourmaline*, warwickite, *apatite*, *chondrodite*, *talc! pyroxene!* rutile, menaccanite, *zircon*, *corundum*, *feldspar*, sphene, calc spar, serpentine, schiller spar (?), silvery mica.

Edenville.—*Apatite*, *chondrodite! hair-brown hornblende!* tremolite, *spinel*, *tourmaline*, *warwickite*, *pyroxene*, *sphene*, *mica*, *feldspar*, *mispickel*, orpiment, *rutile*, menaccanite, scorodite, copper pyrites.

West Point.—*Feldspar*, *mica*, scapolite, *sphene*, *hornblende*, allanite.

PUTNAM CO.—Carmel (Brown's quarry).—Anthophyllite, schiller spar (?), orpiment, mispickel, epidote.

Cold Spring.—Chabazite, mica, sphene, epidote.

Patterson.—*White pyroxene! calc spar*, *asbestus*, *tremolite*, dolomite, massive pyrite.

Phillipstown.—*Tremolite*, *amianthus*, *serpentine*, *sphene*, *diopside*, *green coccolite*, hornblende, *scapolite*, stilbite, mica, laumontite, gurhofite, calc spar, magnetic iron, chromite.

Phillips Ore Bed.—Hyalite, *actinolite*, *massive pyrite.*

RENSSELAER CO.—Hoosic.—Nitrogen springs.

Lansingburgh.—Epsomite, *quartz crystals*, *pyrite.*

Troy.—*Quartz crystals*, *pyrite*, *selenite.*

RICHMOND CO.—Rossville.—Lignite, *cryst. pyrite.*

Quarantine.—*Asbestus*, *amianthus*, aragonite, *dolomite*, *gurhofite*, brucite, serpentine, *talc*, magnesite.

ROCKLAND CO.—Caldwell.—*Calcite*
Grassy Point.—Serpentine, actinolite.
Haverstraw.—*Hornblende*, barite.
Ladentown.—Zircon, malachite, cuprite.
Piermont.—Datolite, stilbite, apophyllite, stellite, prehnite, thomsonite, calcite, chabazite.
Stony Point.—Cerolite, lamellar hornblende, asbestus.

ST. LAWRENCE CO.—Canton.—*Massive pyrite*, *calcite*, brown tourmaline, *sphene*, *serpentine*, talc, *rensselaerite*, pyroxene, specular iron, chalcopyrite.

Dekalb.—*Hornblende*, barite, *fluorite*, *tremolite*, *tourmaline*, blende, graphite, pyroxene, quartz (spongy), serpentine.

Edwards.—*Brown and silvery mica!* scapolite, apatite, *quartz crystals*, actinolite, tremolite, specular iron, serpentine, magnetite.

Fine.—*Black mica*, hornblende.

Fowler.—*Barite*, *quartz crystals! specular iron*, *blende*, galenite, tremolite, chalcedony, bog ore, satin spar (assoc. with serpentine), iron and copper pyrites, actinolite, *rensselaerite* (near Somerville).

Gouverneur.—*Calcite! serpentine! hornblende! scapolite! orthoclase*, *tourmaline!* idocrase (one mile south of G.), pyroxene, apatite, *rensselaerite*, serpentine, *sphene*, fluorite, barite (farm of Judge Dodge), black *mica*, phlogopite, *tremolite!* asbestus, *specular iron*, graphite, idocrase; (near Somerville in serpentine) *spinel*, houghite, scapolite, *phlogopite*, dolomite; three-quarters of a mile west of Somerville, *chondrodite*, spinel; two miles north of Somerville, *apatite*, pyrite, *brown tourmaline!!*

Hammond.—*Apatite! zircon!* (farm of Mr. Hardy), *orthoclase* (loxolase), *pargasite*, barite, pyrite, purple fluorite, dolomite.

Hermon.—*Quartz crystals*, *specular iron*, *spathic iron*, pargasite, pyroxene, serpentine, tourmaline, bog-iron ore.

Macomb.—Blende, mica, *galenite* (on land of James Averil), sphene.

Mineral Point, Morristown.—Fluorite, blende, galenite, *phlogopite* (Pope's Mills), barite.

Ogdensburg.—Labradorite.

Pitcairn.—Satin spar, associated with serpentine.

Potsdam.—*Hornblende!*—eight miles from Potsdam on road to Pierrepont, *feldspar*, *tourmaline*, *black mica*, hornblende.

Rossie (Iron Mines).—*Barite*, *specular iron*, coralloidal aragonite in mines near Somerville, limonite, *quartz* (sometimes stalactitic at Parish iron mine), *pyrite*, *pearl spar*.

Rossie Lead Mine.—*Calcite! galenite! pyrite*, *celestite*, chalcopyrite, *spathic iron!* cerussite, anglesite, *octahedral fluor*, *black phlogopite*.

Elsewhere in Rossie.—*Calcite*, barite, quartz crystals, chondrodite (near Yellow Lake), *feldspar! pargasite! apatite*, *pyroxene*, hornblende, sphene, zircon, *mica*, fluorite, serpentine, automolite, pearl spar, graphite.

Russel.—*Pargasite*, *specular iron*, *quartz* (dodec.), calcite, serpentine, rensselaerite, magnetite.

SARATOGA CO.—Greenfield.—*Chrysoberyl! garnet! tourmaline! mica*, *feldspar*, apatite, graphite, aragonite (in iron mines).

SCHOHARIE CO.—Ball's Cave, and others.—Calcite, stalactites.
Carlisle.—*Fibrous sulphate of baryta*, *cryst. and fib. carbonate of lime.*
Middlebury.—Anthracite, calcite.
Sharon.—Calcareous tufa.
Schoharie.—Fibrous celestite, *strontianite! cryst. pyrites!*

SENECA CO.—Canoga.—*Nitrogen springs.*

SULLIVAN CO.—Wurtzboro'.—*Galenite*, *blende*, *pyrite*, *chalcopyrite.*

TOMPKINS CO.—Ithaca.—Calcareous tufa.

ULSTER CO.—Ellenville.—*Galenite*, blende, *chalcopyrite! quartz*, *brookite.*
Marbletown.—Pyrite.

WARREN CO.—Caldwell.—*Massive feldspar.*

Chester.—*Pyrite*, tourmaline, rutile, chalcopyrite.
Diamond Isle (Lake George).—*Calcite, quartz crystals.*
Glenn's Falls.—Rhomb spar.
Johnsburg.—*Fluorite ! zircon ! ! graphite, serpentine, pyrite.*

WASHINGTON CO.—Fort Ann.—*Graphite*, serpentine.
Granville.—*Lamellar pyroxene*, massive feldspar, epidote.

WAYNE CO.—Wolcott.—Barite.

WESTCHESTER CO.—Anthony's Nose.—*Apatite*, pyrite, *calcite !* in very large tabular crystals grouped, and sometimes incrusted with drusy quartz.
Davenport's Neck.—*Serpentine*, garnet, sphene.
Eastchester.—Blende, copper and iron pyrites, dolomite.
Hastings.—*Tremolite, white pyroxene.*
New Rochelle.—*Serpentine*, brucite, quartz, *mica*, tremolite, garnet, magnesite.
Peekskill.—Mica, feldspar, hornblende, stilbite, sphene.
Rye.—*Serpentine, chlorite, black tourmaline*, tremolite.
Singsing.—*Pyroxene, tremolite, pyrite*, beryl, azurite, green malachite, white lead ore, pyromorphite, anglesite, vauquelinite, galenite, native silver, chalcopyrite.
West Farms.—Apatite, tremolite, garnet, stilbite, heulandite, chabazite, epidote, sphene.
Yonkers.—*Tremolite*, apatite, calcite, analcite, *pyrite*, tourmaline.
Yorktown.—*Sillimanite, monazite*, magnetite.

NEW JERSEY.

Andover Iron Mine (Sussex Co.).—Willemite, brown garnet.
Allentown (Monmouth Co.).—*Vivianite, dufrenite.*
Belville.—Copper mines.
Bergen.—*Calcite ! datolite ! pectolite* (called stellite) ! *analcite, apophyllite ! prehnite*, sphene, *stilbite, natrolite*, heulandite, laumontite, *chabazite*, pyrite, pseudomorphous steatite imitative of apophyllite.
Brunswick.—Copper mines; *native copper, malachite, mountain leather.*
Bryam.—Chondrodite, *spinel*, at Roseville, *epidote.*
Cantwell's Bridge (Newcastle Co.), three miles west.—Vivianite.
Danville (Jemmy Jump Ridge).—*Graphite*, chondrodite, augite, mica.
Flemington.—*Copper mines.*
Frankfort.—*Serpentine.*
Franklin and **Sterling.**—*Spinel ! garnet ! rhodonite ! willemite ! franklinite ! red zinc ore dysluite ! hornblende, tremolite, chondrodite, white scapolite, black tourmaline, epidote, pink calcite, mica*, actinolite, augite, sahlite, coccolite, asbestus, *jeffersonite* (augite), calamine, graphite, fluorite, beryl, galenite, serpentine, honey-colored sphene, quartz, chalcedony, amethyst, zircon, molybdenite, vivianite, *tephroite*, rhodochrosite, aragonite. Also *algerite* in gran. limestone.
Franklin and **Warwick Mts.**—*Pyrite.*
Greenbrook.—Copper mines.
Griggstown.—Copper mines.
Hamburgh.—One mile north, *spinel ! tourmaline, phlogopite, hornblende, limonite*, specular iron.
Hoboken.—Serpentine (marmolite), *brucite, nemalite* (or fibrous brucite), aragonite, dolomite.
Hurdstown.—*Apatite*, magnetic pyrites, magnetite.
Imleytown.—Vivianite
Lockwood.—*Graphite, chondrodite, talc, augite, quartz, green spinel.*
Montville (Morris Co.).—Serpentine, *chrysotile.*
Mullica Hill (Gloucester Co.).—*Vivianite* lining belemnites and other fossils.
Newton.—*Spinel*, blue, pink, and white corundum, *mica, idocrase, hornblende, tourmaline, scapolite*, rutile, pyrite, talc, calcite, barite, *pseudomorphous steatite.*
Paterson.—*Datolite.*

PENNSYLVANIA.

BERKS CO.—Morgantown.—At Jones's mines, one mile east of Morgantown, *green malachite* *chrysocolla*, *magnetite*, pyrite, chalcopyrite, aragonite, talc; two miles N.E. from Jones's mine, graphite, sphene; at Steele's mine, one mile N.W. from St. Mary's, Chester Co., *magnetite*, micaceous iron, coccolite, brown garnet.

READING.—*Smoky quartz* crystals, *zircon*, stilbite, iron ore; at Eckhardt's Furnace, *allanite* with *zircon*.

BUCKS CO.—BUCKINGHAM Township.—Crystallized quartz.

SOUTHAMPTON.—Near the village of Feasterville, in the quarry of Geo. Van Arsdale, *graphite*, pyroxene, sahlite, coccolite, *sphene*, green mica, calcite, *wollastonite*, glassy feldspar sometimes opalescent, phlogopite, *blue quartz*, garnet, molybdenite, zircon, pyrite, moroxite.

CARBON CO.—SUMMIT HILL, in coal mines.—*Kaolinite*.

CHESTER CO.—BIRMINGHAM TOWNSHIP.—Amethyst, *smoky quartz*, serpentine; in Ab'm Darlington's lime quarry, calcite.

EAST BRADFORD.—Near Buffington's bridge on the Brandywine, green, blue, and gray cyanite, the gray cyanite is found loose in the soil in crystals; on the farms of Dr. Elwyn, Mrs. Foulke, Wm. Gibbons, and Saml. Entrikin, *amethyst*. At Strode's mill, asbestus, *magnesite*, anthophyllite, oligoclase, drusy quartz, *collyrite?* on Osborne's Hill, *wad*, *manganesian garnet* (massive), *sphene*, schorl; at Caleb Cope's lime quarry, *fetid dolomite*, necronite, garnets, blue cyanite, *yellow actinolite in talc;* near the Black Horse Inn, *indurated talc*, rutile; on Amor Davis' farm, *orthite!* massive, from a grain to lumps of one pound weight; near the paper-mill on the Brandywine, *zircon*, associated with *titaniferous iron* in blue quartz.

WEST BRADFORD.—Near the village of Marshalton, *green cyanite*, rutile, scapolite, pyrite, staurolite; at the Chester County Poor-house limestone quarry, *chesterlite!* in crystals implanted on dolomite, *rutile!* in brilliant acicular crystals, which are finely terminated, calcite in scalenohedrons, zoisite, *damourite?* in radiated groups of crystals on dolomite, *quartz crystals*.

CHARLESTOWN.—*Pyromorphite*, *cerussite*, *galenite*, quartz.

SOUTH COVENTRY.—In Chrisman's limestone quarry, near Coventry village, augite, sphene, graphite, *zircon* in iron ore (about half a mile from the village).

EAST FALLOWFIELD.—Soapstone.

EAST GOSHEN.—Serpentine, *asbestus*.

WEST GOSHEN.—On the Barrens, one mile north of West Chester, amianthus, serpentine, cellular quartz, jasper, chalcedony, drusy quartz, chlorite, marmolite, indurated talc, *magnesite* in radiated crystals on serpentine, hematite, *asbestus;* near R. Taylor's mill, chromite in octahedral crystals, *deweylite*, *radiated magnesite*, aragonite, *staurolite*, garnet, asbestus, epidote; *zoisite* on hornblende at West Chester water-works (not accessible at present).

NEW GARDEN.—At Nivin's limestone quarry, *brown tourmaline*, *necronite*, scapolite, apatite, brown and green mica, rutile, *aragonite*, *fibrolite*, *kaolinite*.

KENNETT.—Actinolite, brown tourmaline, brown mica, *epidote*, tremolite, scapolite, *aragonite;* on Wm. Cloud's farm, *sunstone!!* sphene. At Pearce's old mill, zoisite, *epidote*, *sunstone;* sunstone occurs in good specimens at various places in the range of hornblende rocks running through this township from N.E. to S.W.

LOWER OXFORD.—Garnets, *pyrite* in cubic crystals.

LONDON GROVE.—Rutile, jasper, chalcedony (botryoidal); in Wm. Jackson's limestone quarry, *yellow tourmaline*, *tremolite;* at Pusey's quarry, rutile, *tremolite*.

EAST MARLBOROUGH.—On the farm of Baily & Brothers, one mile south of Unionville, bright *yellow* and nearly white *tourmaline*, *chesterlite*, *albite;* near Marlborough meeting-house, epidote, serpentine, acicular black tourmaline in white quartz; *zircon* in small perfect crystals loose in the soil at Pusey's saw-mill, two miles S.W. of Unionville.

WEST MARLBOROUGH.—Near Logan's quarry, staurolite, cyanite, yellow tourmaline, rutile, garnets; near Doe Run village, *hematite*, scapolite, *tremolite;* in R. Baily's limestone quarry, two and a half miles S.W. of Unionville, *fibrous tremolite*, *cyanite*, scapolite.

NEWLIN.—On the serpentine barrens, one and a half miles N.E. of Unionville, *corundum!* massive and crystallized, also in crystals in *albite*, often in loose crystals covered with a thin coating of steatite, talc, picrolite, brucite, *green tourmaline*, with flat pyramidal terminations in albite, *unionite* (rare), *euphyllite*, mica in hexagonal crystals, *feldspar*, *beryl!* in hexagonal crystals, one of which weighs 51 lbs., chromic iron, drusy quartz, green quartz, actinolite, *emerylite*, chloritoid, diallage, *oligoclase;* on Johnson Patterson's farm, massive *corundum*, titaniferous iron, *clinochlore*, *emerylite*, sometimes colored green by chrome, albite, *orthoclase*, halloysite, margarite, garnets, *beryl;* on J. Lesley's farm, *corundum*, crystallized and in massive lumps, one of which weighed 5200 lbs., *diaspore!! emerylite! euphyllite crystallized! green tourmaline*, transparent crystals in the *euphyllite*, orthoclase; two miles N. of Unionville, *magnetite* in octahedral crystals; one mile E. of Unionville *hematite;* in Edwards's old limestone quarry, purple fluor, rutile.

East Nottingham.—*Sand chrome*, *asbestus*, *chromic iron* in octahedral crystals.

West Nottingham.—At Scott's chrome mine, *chromic iron*, *foliated talc*, marmolite, serpentine *chalcedony*, *rhodochrome*; at the magnesia quarry, *deweylite*, marmolite, magnesite, leelite, serpentine sand chrome.

East Pikeland.—Iron ore.

West Pikeland.—In the iron mines near Chester Springs, *gibbsite*, *zircon*, *hydro-hematite*, *hematite* (stalactitical and in geodes).

Penn.—Garnets, agalmatolite.

Pennsbury.—On John Craig's farm, brown garnets, *mica*; on J. Dilworth's farm, near Fairville, *muscovite!* in hexagonal prisms from one quarter to seven inches in diameter; in the village of Fairville, *sunstone*; near Brinton's ford on the Brandywine, *chondrodite*, *sphene*, diopside, *augite*, coccolite: at Mendenhall's old limestone quarry, *fetid quartz*, sunstone.

Pocopson.—On the farms of John Entrikin and Jos. B. Darlington, *amethyst*.

Sadsbury.—*Rutile!!* splendid geniculated crystals are found loose in the soil for seven miles along the valley, and particularly near the village of Parkesburg, where they sometimes occur weighing one pound, doubly geniculated and of a deep red color; near Sadsbury village, *amethyst*, tourmaline, epidote, *milk quartz*.

Schuylkill.—In the railroad tunnel at Phœnixville, *dolomite!* sometimes coated with pyrite, quartz crystals, yellow blende, brookite, *calcite* in hexagonal crystals enclosing *pyrite*; at the Wheatley, Brookdale, and Chester County lead mines, one and a half miles S. of Phœnixville, *pyromorphite! cerussite! galenite*, *anglesite!!* quartz crystals, chalcopyrite, barite, *fluorite* (white), *stolzite*, *wulfenite! calamine*, *vanadinite*, *blende! mimetene!* native copper, malachite, *azurite*, limonite, *calcite*, *sulphur*, pyrite, indigo copper, black oxide of copper, phosphochalcite, gersdorffite.

Thornbury.—On Jos. H. Brinton's farm, *muscovite* containing acicular crystals of tourmaline, *rutile*, titaniferous iron.

Tredyffrin.—*Pyrite* in cubic crystals loose in the soil.

Uwchlan.—Massive *blue quartz*, *graphite*.

Warren.—*Melanite*, feldspar.

Willistown.—*Magnetite*, *chromite*, actinolite, asbestus.

West-Town.—On the serpentine rocks 3 miles S. of West Chester, *clinochlore! jefferisite!* mica, asbestus, actinolite, magnesite, *talc*, titaniferous iron.

East Whiteland.—*Pyrite*, in very perfect cubic crystals, is found on nearly every farm in this township, quartz crystals found loose in the soil.

West Whiteland.—At Gen. Trimble's iron mine, *stalactitical hematite! wavellite!!* in radiated stalactites.

Warwick.—At the Elizabeth mine, and Keim's old iron mine adjoining, one mile N. of Knauertown, *aplome garnet!* in brilliant dodecahedrons, *flosferri*, *pyroxene*, *micaceous iron*, *pyrite* in bright octahedral crystals in calcite, chalcopyrite massive and in single tetrahedral crystals, magnetite, *fascicular hornblende! bornite*, malachite, *brown garnet*, calcite, *byssolite!* serpentine; near the village of St. Mary's, magnetite in dodecahedral crystals, *melanite*, *garnet*, *actinolite* in small radiated nodules; at the Hopewell iron mine, one mile N.W. of St. Mary's, *magnetite* in octahedral crystals.

COLUMBIA CO.—At Webb's mine, yellow blende in calcite; near Bloomsburg, cryst. magnetite.

DAUPHIN CO.—Near Hammelstown.—Green garnets, cryst. *smoky quartz*, feldspar.

DELAWARE CO.—Aston Township.—*Amethyst*, *corundum*, emerylite, staurolite, *fibrolite*, black tourmaline, pearl mica, *sunstone*, *asbestus*, anthophyllite, steatite; near Tyson's mill, garnet, staurolite; at Peter's mill-dam in the creek, *pyrope garnet*.

Birmingham.—*Fibrolite*, *kaolin* (abundant), crystals of rutile, *amethyst*; at Bullock's old quarry, zircon, *bucholzite*, nacrite, yellow crystallized quartz, *feldspar*.

Blue Hill.—Green quartz crystals.

Chester.—*Amethyst*, *black tourmaline*, *beryl*, *crystals of feldspar*, *garnet*, cryst. pyrite, *molybdenite*, *molybdic ochre*, chalcopyrite, kaolin.

Chichester.—Near Trainer's mill-dam, *beryl*, tourmaline, crystals of *feldspar*, kaolin; on Wm. Eyre's farm, *tourmaline*.

Concord.—*Crystals of mica*, *crystals of feldspar*, *kaolin* abundant, *drusy quartz* of a blue and green color, meerschaum, stellated *tremolite*, some of the rays 6½ in. diameter, *anthophyllite*, fibrolite acicular crystals of *rutile*, pyrope in quartz, amethyst, actinolite, *manganesian garnet*, *beryl*; in Green's creek, *pyrope garnet*.

Darby.—*Blue* and *gray cyanite*, garnet, staurolite, zoisite, quartz, beryl, chlorite, mica, limonite

Edgemont.—*Amethyst*, oxide of manganese, crystals of *feldspar*; one mile east of Edgemont Hall, *rutile* in quartz.

Green's Creek.—*Garnet* (so-called pyrope).

Marple.—*Tourmaline*, *andalusite*, amethyst, *actinolite*, *anthophyllite*, talc, *radiated actinolite in talc*, chromite, *drusy quartz*, beryl, cryst. pyrite, *titanic iron in quartz*, chlorite.

Middletown.—*Amethyst*, *beryl*, black mica, *mica* with reticulated magnetite between the plates, *manganesian garnets!* large trapezohedral crystals, some 8 in. in diameter, indurated talc, hexagonal crystals of *rutile*, *crystals of mica*, *green quartz! anthophyllite*, radiated tourmaline, staurolite, titanic iron, fibrolite, serpentine; at Lenni, *chlorite*, green and bronze *vermiculite! green feldspar*; at Mineral Hill, fine crystals of *corundum*, one of which weighs 1½ lbs., *actinolite* in great variety, bronzite, *green feldspar*, *moonstone*, *sunstone*, *graphic granite*, magnesite, *octahedral crystals of chromite* in great quantity, *beryl*, chalcedony, asbestus, *fibrous hornblende*, rutile, staurolite.

Newtown.—Serpentine, hematite.

Upper Providence.—*Anthophyllite*, *tremolite*, *radiated asbestus*, *radiated actinolite*, tourmaline, *beryl*, *green feldspar*, *amethyst* (one found on Morgan Hunter's farm weighing over 7 lbs.), *andalusite* (one terminated crystal found on the farm of Jas. Worrall weighs 7½ lbs.); at Blue Hill, very fine crystals of *blue quartz* in chlorite, *amianthus* in serpentine.

Lower Providence.—*Amethyst*, *green mica*, garnet, large crystals of *feldspar!* (some over 100 lbs. in weight).

Radnor.—*Garnet*, marmolite, deweylite, chromite, asbestus, magnesite, talc, blue quartz, picrolite, limonite, magnetite.

Springfield.—*Andalusite*, *tourmaline*, beryl, titanic iron, garnet; on Fell's Laurel Hill, beryl, garnet; near Beattie's mill, staurolite, apatite; near Lewis's paper-mill, tourmaline, *mica*.

Thornbury.—*Amethyst*.

HUNTINGDON CO.—Near Frankstown.—In the bed of a stream and on the side of a hill, *fibrous celestite* (abundant), *quartz crystals*.

LANCASTER CO.—Drumore Township.—Quartz crystals.

Fulton.—At Wood's chrome mine, near the village of Texas, *brucite!!* zaratite (emerald nickel), *pennite! ripidolite! kammererite! baltimorite*, *chromic iron*, williamsite, *chrysolite!* marmolite, *picrolite*, hydromagnesite, *dolomite*, magnesite, *aragonite*, calcite, serpentine, hematite, menaccanite, genthite, chrome-garnet, bronzite; at Low's mine, *hydromagnesite*, *brucite* (lancasterite), *picrolite*, magnesite, *williamsite*, *chromic iron*, talc, zaratite, baltimorite, serpentine, hematite; on M. Boice's farm, one mile N.W. of the village, *pyrite*, in cubes and various modifications, *anthophyllite*; near Rock Springs, *chalcedony*, carnelian, *moss agate*, *green tourmaline* in talc, titanic iron, *octahedral magnetite in chlorite*; at Reynold's old mine, calcite, *talc*, picrolite, *chromite*.

Gap Mines.—Chalcopyrite, *pyrrhotite* (niccoliferous), *millerite* in botryoidal radiations, *vivianite!* (rare), actinolite, *pyroxene* crystals, *siderite*.

Pequea Valley.—Eight miles south of Lancaster, argentiferous galenite (said to contain 250 to 300 oz. of silver to the ton?), vauquelinite at Pequea mine; four miles N.W. of Lancaster, on the Lancaster and Harrisburg Railroad, *calamine*, galenite, blende; *pyrite* in cubic crystals is found in great abundance near the city of Lancaster; at the Lancaster zinc mines, *calamine*, blende, tennantite? *smithsonite* (pseud. of dolomite), *aurichalcite*.

LEBANON CO.—Cornwall.—*Magnetite*, *pyrite* (cobaltiferous), chalcopyrite, *native copper*, *azurite*, *malachite*, *chrysocolla*, *cuprite*, *allophane*, *brochantite*, serpentine, quartz pseudomorphs; *galenite* (with octahedral cleavage), fluorite.

LEHIGH CO.—Friedensville.—At the zinc mines, *calamine*, *smithsonite*, hydrozincite, massive blende, sulphid of cadmium, quartz, allophane, zinciferous clay; near Allentown, magnetite, pipe-iron ore; near Bethlehem, on S. Mountain, *allanite*, with zircon and altered sphene in syenite, magnetite, black spinel, tourmaline.

MONROE CO.—In Cherry Valley.—*Calcite*, chalcedony, quartz; in Poconac Valley, near Judge Mervine's, cryst. quartz.

MONTGOMERY CO.—Conshohocken.—Fibrous tourmaline, titanic iron, aventurine quartz, phyllite; in the quarry of Geo. Bullock, *calcite* in hexagonal prisms, aragonite.

Lower Providence.—At the Perkiomen lead and copper mines, near the village of Shannonville, azurite, *blende*, *galenite*, pyromorphite, cerussite, wulfenite, anglesite, barite, calamine, chalcopyrite, malachite, chrysocolla, *brown spar*.

White Marsh.—At D. O. Hitner's iron mine, five and a half miles from Spring Mills, limonite in geodes and stalactites, *göthite*, pyrolusite, wad, lepidocrocite; at Edge Hill Street, North Pennsylvania Railroad, titanic iron; one mile S.W. of Hitner's iron mine, *limonite*, velvety, stalactitic, and fibrous, fibres three inches long, *göthite*, pyrolusite, *velvet manganese*, wad; near Marble Hall, a Hitner's marble quarry, white marble, granular barite, resembling marble; at Spring Mills, limonite; at Flat Rock Tunnel, opposite Manayunk, *stilbite*, *heulandite*, *chabasite*, beryl, feldspar, mica.

NORTHUMBERLAND CO.—Opposite Selinsgrove.—Calamine.

NORTHAMPTON CO.—Near Easton.—*Zircon!* (exhausted), nephrite, coccolite, tremolite pyroxene, sahlite, limonite, magnetite, purple calcite.

PHILADELPHIA CO.—Frankford.—On the Philadelphia, Trenton and Connecting Railroad, basinite; at the quarries on Frankford Creek, stilbite, molybdenite, hornblende; on the Connecting Railroad, wad, earthy cobalt.

Fairmount Water Works.—In the quarries opposite Fairmount, *lime uranite! copper uranite*, crystals of *feldspar*, beryl, pseudomorphs after beryl, tourmaline, albite, wad, menaccanite.

Gorgas' and Crease's Lane.—Tourmaline, cyanite, staurolite, hornstone.

Hestonville.—Alunogen, iron alum.

Heft's Mill.—Alunogen, tourmaline, cyanite, titanic iron.

Manayunk.—At the soapstone quarries above Manayunk, talc, *steatite*, chlorite, vermiculite, *anthophyllite*, staurolite, dolomite, apatite, asbestus, brown spar, epsomite.

Magarge's Paper-mill.—Staurolite, titanic iron, hyalite, *apatite*, green mica, iron garnets in great abundance.

McKinney's Quarry, on Rittenhouse Lane.—Feldspar, *apatite*, *stilbite*, natrolite, *heulandite*, epidote, hornblende, erubescite, malachite.

SCHUYLKILL CO.—Tamaqua, near Pottsville, in coal mines.—*Kaolinite.*

DELAWARE.

NEWCASTLE CO.—Brandywine Springs.—*Bucholzite*, *fibrolite* abundant, sahlite, pyroxene; Brandywine Hundred, muscovite, enclosing reticulated magnetite.

Dixon's Feldspar Quarries, six miles N.W. of Wilmington (these quarries have been worked for the manufacture of porcelain).—*Adularia*, *albite*, *oligoclase*, *beryl*, *apatite*, *cinnamon-stone!!* (both granular like that from Ceylon, and crystallized, rare), magnesite, serpentine, asbestus, black *tourmaline!* (rare), *indicolite!* (rare), sphene in pyroxene, cyanite.

Dupont's Powder Mills.—"Hypersthene."

Eastburn's Limestone Quarries, near the Pennsylvania line.—*Tremolite*, *bronzite*.

Quarryville.—Garnet, spodumene, fibrolite, sillimanite.

Near Newark, on the railroad.—Sphærosiderite on drusy quartz, jasper (ferruginous opal), cryst. spathic iron in the cavities of cellular quartz.

Way's Quarry, two miles south of Centreville.—*Feldspar* in fine cleavage masses, *apatite*, *mica*, *deweylite*, *granular quartz*.

Wilmington.—In Christiana quarries. *metalloidal diallage.*

Kennett Turnpike, near Centreville.—Cyanite and garnet.

HARFORD CO.—Cerolite.

KENT CO.—Near Middletown, in Wm. Polk's marl pits.—*Vivianite!*

On Chesapeake and Delaware Canal.—Retinasphalt, pyrite, amber

SUSSEX CO.—Near Cape Henlopen.—Vivianite.

MARYLAND.

Baltimore (Jones's Falls, 1½ miles from B.).—Chabazite (haydenite), heulandite (beaumontite of Levy), pyrite, lenticular carbonate of iron, *mica*, *stilbite*.

Sixteen miles from Baltimore, on the Gunpowder.—*Graphite.*

Twenty-three miles from B., on the Gunpowder.—*Talc.*

Twenty-five miles from B., on the Gunpowder.—*Magnetite*, *sphene*, pycnite,

Thirty miles from B., in Montgomery Co., on farm of S. Eliot.—Gold in quartz.

Eight to twenty miles north of B., in limestone.—*Tremolite, augite, pyrite,* brown and yellow tourmaline.

Fifteen miles north of B.—*Sky-blue chalcedony* in granular limestone.

Eighteen miles north of B., at Scott's mills.—*Magnetite,* cyanite.

Bare Hills.—*Chromite, asbestus, tremolite, talc,* hornblende, serpentine, chalcedony, meerschaum baltimorite, *chalcopyrite,* magnetite.

Cape Sable, near Magothy R.—Amber, pyrite, alum slate.

Carroll Co.—Near Sykesville, Liberty Mines, gold, magnetite, *pyrite* (*octahedrons*), *chalcopyrite,* linnæite (carrollite); at Patapsco Mines, near Finksburg, bornite, *malachite,* siegenite, *linnæite, remingtonite,* magnetite, *chalcopyrite;* at Mineral Hill mine, *bornite,* chalcopyrite, ore of *nickel* (see above), gold, magnetite.

Cecil Co., north part.—*Chromite* in serpentine.

Cooptown, Harford Co.—Olive-colored *tourmaline, diallage, talc* of green, blue, and rose colors, *ligniform asbestus, chromite, serpentine.*

Deer Creek.—*Magnetite!* in chlorite slate.

Frederick Co.—Old Liberty mine, near Liberty Town, black copper, malachite, chalcocite, specular iron; at Dollyhyde mine, *bornite,* chalcopyrite, pyrite, argentiferous galenite in dolomite.

Montgomery Co.—*Oxyd of manganese.*

Somerset and Worcester Cos., north part.—*Bog-iron ore, vivianite.*

St. Mary's River.—*Gypsum!* in clay.

VIRGINIA AND DISTRICT OF COLUMBIA.

Albemarle Co., a little west of the Green Mts.—*Steatite, graphite,* galena.

Amherst Co., along the west base of Buffalo ridge.—*Copper ores,* etc.

Augusta Co.—At Weyer's (or Weir's) cave, sixteen miles northeast of Staunton, and eighty-one miles northwest of Richmond, calcite, stalactites.

Buckingham Co.—*Gold* at Garnett and Moseley mines, also pyrite, pyrrhotite, calcite, garnet; at Eldridge mine (now London and Virginia mines) near by, and the Buckingham mines near Maysville, gold, auriferous pyrite, chalcopyrite, tennantite, *barite; cyanite, tourmaline, actinolite.*

Chesterfield Co.—Near this and Richmond Co., bituminous coal, native coke.

Culpepper Co, on Rapidan river.—Gold, pyrite.

Franklin Co.—Grayish steatite.

Fauquier Co., Barnet's mills.—Asbestus; gold mines, *barite, calcite.*

Fluvanna Co.—Gold at Stockton's mine; also tetradymite at "Tellurium mine."

Phenix Copper mines.—*Chalcopyrite,* etc.

Georgetown, D. C.—Rutile.

Goochland Co.—Gold mines (Moss and Busby's).

Harper's Ferry, on both sides of the Potomac.—Thuringite (owenite) with quartz.

Jefferson Co., at Shepherdstown.—Fluor.

Kenawha Co.—At Kenawha, *petroleum,* brine springs, cannel coal.

Loudon Co.—*Tabular quartz, prase, pyrite, talc, chlorite, soapstone,* asbestus, *chromite, actinolite, quartz crystals; micaceous iron,* bornite, malachite, epidote, near Leesburg (Potomac mine).

Louisa Co.—Walton gold mine, gold, pyrite, chalcopyrite, argentiferous galenite, siderite, blende, anglesite; boulangerite, blende (at Tinder's mine).

Nelson Co.—Galenite, chalcopyrite, malachite.

Orange Co.—Western part, Blue Ridge, specular iron; gold at the Orange Grove and Vaucluse gold mines, worked by the "Freehold" and "Liberty" Mining Companies.

Rockbridge Co., three miles southwest of Lexington.—Barite.

Shenandoah Co., near Woodstock.—Fluorite.

Mt. Alto, Blue Ridge.—Argillaceous iron ore.

Spotsylvania Co., two miles northeast of Chancellorville.—*Cyanite;* gold mines at the junction of the Rappahannock and Rapidan; on the Rappahannock (Marshall mine); Whitehall mine, affording also tetradymite.

Stafford Co., eight or ten miles from Falmouth.—Micaceous iron, gold, tetradymite, silver, galenite, vivianite.

Washington Co., eighteen miles from Abingdon.—*Rock salt* with *gypsum.*

Wythe Co. (Austin's mines).—*Cerussite, minium, plumbic ochre,* blende, *calamine, galenite.*

On the Potomac, twenty-five miles north of Washington city.—*Native sulphur* in gray compact limestone.

NORTH CAROLINA.

Ashe Co.—Malachite, chalcopyrite.

Buncombe Co.—Corundum (from a boulder), *margarite*, corundophilite, *garnet*, chromite, barite *fluorite*, rutile, iron ores, oxyd of manganese, *zircon*.

Burke Co.—Gold, monazite, zircon, beryl, *corundum*, *garnet*, sphene, *graphite*, iron ores.

Cabarrus Co.—Phenix Mine, gold, barite, *chalcopyrite*, auriferous pyrite, quartz pseudomorph after barite, tetradymite; Pioneer mines, *gold*, limonite, pyrolusite, *barnhardtite*, *wolfram*, *scheelite*, tungstate of copper, tungstite, diamond, chrysocolla, chalcocite, molybdenite, *chalcopyrite*, *pyrite*; White mine, needle ore, chalcopyrite, barite; Long and Muse's mine, argentiferous galenite, pyrite, chalcopyrite, limonite; Boger mine, tetradymite; Fink mine, valuable copper ores; Mt. Makins, tetrahedrite, magnetite, talc, blende, pyrites, proustite, galenite; Baugle mine, scheelite.

Caldwell Co.—Chromite.

Chatham Co.—Mineral coal, pyrite.

Cherokee Co.—Iron ores, gold, galenite, corundum, rutile.

Davidson Co.—King's, now Washington mine, native silver, cerussite, anglesite, scheelite, pyromorphite, galenite, blende, malachite, black copper, *wavellite*, garnet, stilbite; five miles from Washington mine, on Faust's farm, gold, *tetradymite*, oxyd of bismuth and tellurium, chalcopyrite, limonite, spathic iron, epidote; near Squire Ward's, gold in crystals, electrum.

Franklin Co.—At Partis mine, diamonds.

Gaston Co.—Iron ores, corundum, margarite; near Crowder's Mountain (in what was formerly Lincoln Co.), *lazulite*, *cyanite*, *garnet*, graphite; also twenty miles northeast, near south end of Clubb's Mtn., lazulite, cyanite, talc, rutile, topaz, *pyrophyllite*.

Guilford Co.—McCulloch copper and gold mine, twelve miles from Greensboro', *gold*, *pyrite*, *chalcopyrite* (worked for copper), *quartz*, spathic iron. The North Carolina Copper Co. are working the copper ore at the old Fentress mine; at Deep River, compact *pyrophyllite* (worked for slate-pencils).

Henderson Co.—*Zircon*, sphene (xanthitane).

Jackson Co.—Alunogen! at Smoky Mt.; at Webster, serpentine, chromite, genthite, *chrysolite*, talc.

Lincoln Co.—Diamond; at Randleman's, *amethyst!* rose quartz.

Macon Co.—Chromite.

McDowell Co.—Brookite, monazite, corundum in small crystals red and white, *zircons*, garnet, beryl, sphene, xenotime, rutile, flexible sandstone, iron ores, pyromelane.

Mecklenburg Co.—Near Charlotte (Rhea and Cathay mines) and elsewhere, *chalcopyrite*, *gold*; chalcotrichite at McGinn's mine; barnhardtite near Charlotte; pyrophyllite in Cotton Stone Mountain, diamond; Flowe mine, scheelite, wolframite; Todd's Branch, *monazite*.

Montgomery Co.—Steele's mine, ripidolite, albite.

Moore Co.—Carbonton, compact pyrophyllite.

Rowan Co.—Gold Hill mines, thirty-eight miles northeast of Charlotte, and fourteen from Salisbury, gold, auriferous pyrite; ten miles from Salisbury, *feldspar* in crystals, *bismuthine*.

Rutherford Co.—*Gold*, *graphite*, bismuthic gold, diamond, euclase, *pseudomorphous quartz*, chalcedony, corundum in small crystals, *epidote*, *pyrope*, brookite, zircon, monazite, rutherfordite, samarskite, *quartz crystals*, itacolumite; on the road to Cooper's Gap, cyanite.

Stokes and Surrey Cos.—Iron ores, graphite.

Union Co.—Lemmond gold mine, eighteen miles from Concord (at Stewart's and Moore's mine), gold, quartz, blende, argentiferous galenite (containing 29·4 oz. of gold and 86·5 oz. of silver to the ton, Genth), pyrite, some chalcopyrite.

Yancey Co.—*Iron ores*, amianthus, *chromite*.

SOUTH CAROLINA.

Abbeville Dist.—Oakland Grove, *gold* (Dorn mine), galenite, pyromorphite, amethyst, garnet.

Anderson Dist.—At Pendleton, *actinolite*, galenite, kaolin, *tourmaline*.

Charleston.—*Selenite*.

Cheowee Valley.—Galenite, tourmaline, gold.

Chesterfield Dist.—Gold (Brewer's mine), talc, chlorite, pyrophyllite, pyrite, native bismuth, carbonate of bismuth, red and yellow ochre, whetstone, enargite.

Darlington.—Kaolin.

Edgefield Dist.—Psilomelane.

Greenville Dist.—Galenite, phosphate of lead, kaolin, chalcedony in buhrstone, beryl, plumbago, epidote, *tourmaline*.

Kershaw Dist.—*Rutile*.

Lancaster Dist.—Gold (Hale's mine), talc, chlorite, cyanite, elastic sandstone, pyrite; gold also at Blackman's mine, Massey's mine, Ezell's mine.

Newberry Dist.—Leadhillite (?).

Pickens Dist.—Gold, manganese ores, kaolin.

Richland Dist.—Chiastolite, novaculite.

Spartanburg Dist.—*Magnetite*, chalcedony, *hematite*; at the Cowpens, limonite, *graphite*, limestone, copperas; Morgan mine, leadhillite, pyromorphite, cerussite.

Sumter Dist.—Agate.

Union Dist.—Fairforest gold mines, pyrite, chalcopyrite.

York Dist.—Limestones, whetstones, witherite, barite.

GEORGIA.

Burke and Scriven Cos.—Hyalite.

Cherokee Co.—At Cauton Mine, chalcopyrite, galenite, clausthalite, plumbogummite, hitchcockite, *mispickel*, lanthanite, *harrisite*, *cantonite*, pyromorphite, automolite, zinc, staurolite, cyanite; at Ball-Ground, spodumene.

Clark Co., near Clarksville.—Gold, *xenotime*, zircon, rutile, cyanite, specular iron, garnet, quartz.

Dade Co.—Halloysite, near Rising Fawn.

Fannin Co.—*Staurolite*, chalcopyrite.

Habersham Co.—*Gold*, iron and copper pyrites, *galenite*, hornblende, garnet, quartz, kaolinite, soapstone, chlorite, *rutile*, iron ores, tourmaline, staurolite, zircon.

Hall Co.—*Gold*, quartz, kaolin, diamond.

Hancock Co.—Agate, chalcedony.

Heard Co.—*Molybdite*, quartz.

Lincoln Co.—*Lazulite* ! ! *rutile* ! ! hematite, cyanite, menaccanite, *pyrophyllite*, gold, itacolumite rock.

Lumpkin Co.—At Field's gold mine near Dahlonega, *gold*, *tetradymite*, pyrrhotite, chlorite, menaccanite, allanite, apatite.

Rabun Co.—Gold, *chalcopyrite*.

Washington Co., near Saundersville.—*Wavellite*, *fire opal*.

ALABAMA.

Bibb Co., Centreville.—*Iron ores*, marble, *barite*, coal, cobalt.

Tuscaloosa Co.—*Coal*, galenite, pyrite, vivianite, limonite, calcite, dolomite, cyanite, steatite, quartz crystals, manganese ores.

Benton Co.—Antimonial lead ore (boulangerite ?).

FLORIDA.

Near Tampa Bay.—Limestone, sulphur springs, chalcedony, carnelian, agate, silicified shells and corals.

KENTUCKY.

Anderson Co.—Galenite, barita.

Clinton Co.—Geodes of quartz.

Crittenden Co.—Galenite, fluorite, calcite.

Cumberland Co.—At Mammoth Cave, *gypsum rosettes* ! calcite, stalactites, nitre, epsomite.

Fayette Co.—Six miles N.E. of Lexington, galenite, barite, witherite, blende.

Livingstone Co., near the line of Union Co.—Galenite, chalcopyrite.

Mercer Co.—At McAfee, *fluorite*, *pyrite*, calcite, barite, celestite.

Owen Co.—Galenite, barite.

TENNESSEE.

Brown's Creek.—Galenite, blende, barite, celestite.

Carter's Co., foot of Roan Mt.—*Sahlite*, magnetite.

Claiborne Co.—*Calamine*, galenite, smithsonite, chlorite, steatite, magnetite.

Cocke Co., near Brush Creek.—Cacoxene ? kraurite, iron sinter, stilpnosiderite, brown hematite

Davidson Co.—Selenite, with granular and snowy *gypsum*, or alabaster, crystallized and compact *anhydrite*, *fluorite* in crystals ? *calcite* in crystals. Near Nashville, blue *celestite* (crystallized, fibrous, and radiated), with *barite* in limestone. Haysboro', galenite, blende, with barite as the gangue of the ore.

Dickson Co.—Manganite.

Jefferson Co.—*Calamine*, galenite, fetid barite.

Knox Co.—Magnesian limestone, *native iron*, *variegated marbles!*

Maury Co.—Wavellite in limestone.

Morgan Co.—Epsom salt, nitrate of lime.

Polk Co., Ducktown mines, southeast corner of State.—*Black copper!* chalcopyrite, pyrite, native copper, bornite, rutile, *zoisite*, galenite, *harrisite*, alisonite, blende, *pyroxene*, *tremolite*, *sulphates of copper and iron* in stalactites, allophane, rahtite, chalcocite (ducktownite), chalcotrichite, azurite, malachite, *pyrrhotite*, limonite.

Roan Co., eastern declivity of Cumberland Mts.—Wavellite in limestone.

Sevier Co., in caverns.—Epsom salt, soda alum, saltpetre, nitrate of lime, *breccia marble*.

Smith Co.—Fluorite.

Smoky Mt., on declivity.—Hornblende, garnet, staurolite.

White Co.—*Nitre*.

OHIO.

Bainbridge (Copperas Mt., a few miles east of B.).—Calcite, barite, pyrite, copperas, alum.

Canfield.—*Gypsum!*

Duck Creek, Monroe Co.—Petroleum.

Lake Erie.—Strontian Island, *celestite!* Put-in Bay Island, *celestite! sulphur!* calcite.

Liverpool.—Petroleum.

Marietta.—Argillaceous iron ore; iron ore abundant also in Scioto and Lawrence Cos.

Ottawa Co.—Gypsum.

Poland.—*Gypsum!*

MICHIGAN.

Brest (Monroe Co.).—*Calcite*, amethystine quartz, apatite, celestite.

Grand Rapids.—*Selenite*, fib. and granular gypsum, *calcite*, *dolomite*, *anhydrite*.

Lake Superior Mining Region.—The four principal regions are Keweenaw Point, Isle Royale, the Ontonagon, and Portage Lake. The mines of Keweenaw Point are along two ranges of elevation, one known as the Greenstone Range, and the other as the Southern or Bohemian Range (Whitney). The copper occurs in the trap or amygdaloid, and in the associated conglomerate. *Native copper! native silver!* chalcopyrite, horn silver, gray copper, manganese ores, epidote, *prehnite*, *laumontite*, *datolite*, heulandite, orthoclase, *analcite*, chabazite, compact datolite, chrysocolla, *mesotype* (Copper Falls mine), *leonhardite* (ib.), *analcite* (ib.), *apophyllite* (at Cliff mine), *wollastonite* (ib.), *calc spar! quartz* (in crystals at Minnesota mine), compact datolite, orthoclase (Superior mine), *saponite*, *black oxyd* of copper (near Copper Harbor, but exhausted), chrysocolla; on Chocolate River, galenite and sulphid of copper; chalcopyrite and native copper at Presq' Isle; at Albion mine, *domeykite;* at Prince Vein, *barite*, *calcite*, *amethyst;* at Michipicoten Ids., copper nickel, stilbite, analcite; at Albany and Boston mine, Portage Lake, *prehnite*, *analcite*, *orthoclase*, cuprite; at Sheldon location, *domeykite*, *whitneyite*, *algodonite;* Isle Royale mine, Portage Lake, compact datolite; Quincy mine, calcite, compact datolite.

Marquette.—Manganite, galenite; twelve miles west at Jackson Mt., and other mines, *hematite*, *limonite*, *göthite!* magnetite, jasper.

Monroe.—Aragonite, apatite.

Point aux Peaux (Monroe Co.).—*Amethystine quartz*, *apatite*, celestite, *calcite*.

Saginaw Bay.—At Alabaster, *gypsum*.

Stony Point (Monroe Co.).—Apatite, amethystine quartz, celestite, calcite.

ILLINOIS.

Gallatin Co., on a branch of Grand Pierre Creek, sixteen to thirty miles from Shawneetown, down the Ohio, and from half to eight miles from this river.—*Violet fluorite!* in carboniferous limestone, barite, *galenite*, blende, brown iron ore.

Hancock Co.—At Warsaw, *quartz geodes!* containing *calcite! chalcedony*, *dolomite*, *blende!* brown spar, pyrite, aragonite, gypsum, bitumen.

Hardin Co.—Near Rosiclare, *calcite*, galenite, blende; five miles back from Elizabethtown, bog iron; one mile north of the river, between Elizabethtown and Rosiclare, *nitre*.

Jo Davies Co.—At Galena, *galenite*, calcite, *pyrite*, blende; at Marsden's diggings, *galenite! blende*, *cerussite*, *pyrite!* in stalactitic forms.

Joliet.—*Marble*.

Quincy.—*Calcite!* pyrite.

Scales Mound.—*Barite*, pyrite.

INDIANA.

Limestone Caverns; Corydon Caves, etc.—*Epsom salt.*

In most of the southwest counties, *pyrite, sulphate of iron*, and *feather alum;* on Sugar Creek, pyrite and *sulphate of iron;* in sandstone of Lloyd Co., near the Ohio, *gypsum;* at the top of the blue limestone formation, *brown spar, calcite.*

MINNESOTA.

North Shore of L. Superior (range of hills running nearly northeast and southwest, extending from Fond du Lac Superieure to the Kamanistiqueia River in Upper Canada).—*Scolecite, apophyllite, prehnite, stilbite, laumontite, heulandite, harmotome*, thomsonite, *fluorite, barite, tourmaline, epidote*, hornblende, calcite, quartz crystals, pyrite, magnetite, steatite, blende, black oxyd of copper, malachite, native copper, chalcopyrite, amethystine quartz, ferruginous quartz, *chalcedony, carnelian, agate*, drusy quartz, hyalite? fibrous quartz, jasper, prase (in the debris of the lake shore), dogtooth spar, augite, native silver, spodumene? arsenate of cobalt? chlorite; between Pigeon Point and Fond du Lac, near Baptism River, saponite (thalite) in amygdaloid.

Kettle River Trap Range.—Epidote, nail-head calcite, amethystine quartz, calcite, undetermined zeolites, saponite.

Stillwater.—Blende.

Falls of the St. Croix.—Green carbonate of copper, native copper, epidote, nail-head spar.

Rainy Lake.—Actinolite, tremolite, fibrous hornblende, garnet, pyrite, magnetite, steatite.

WISCONSIN.

Big Bull Falls (near).—Bog iron.

Blue Mounds.—Cerussite.

Lac du Flambeau R.—Garnet, cyanite.

Left Hand R. (near small tributary).—Malachite, chalcocite, native copper, red copper ore earthy malachite, epidote, chlorite! quartz crystals.

Linden.—*Galenite, smithsonite, hydrozincite.*

Mineral Point and vicinity.—Copper and lead ores, chrysocolla, *azurite!* chalcopyrite, malachite *galenite*, cerussite, anglesite, blende, *pyrite*, barite, *calcite, marcasite, smithsonite!* (so-called dry-bone)

Montreal River Portage.—Galenite in gneissoid granite.

Sank Co.—Specular iron! malachite, chalcopyrite.

Shullsburg.—*Galenite!* blende, pyrite; at Emett's diggings, *galenite* and pyrite.

IOWA.

Du Buque Lead Mines, and elsewhere.—*Galenite! calcite, blende*, black oxyd of manganese; at Ewing's and Sherard's diggings, *smithsonite*, calamine; at Des Moines, quartz crystals, selenite; Makoqueta R., *brown iron ore;* near Durango, galenite.

Cedar River, a branch of the Des Moines.—*Selenite* in crystals, in the bituminous shale of the coal measures; also elsewhere on the Des Moines, gypsum abundant; argillaceous iron ore, spathic iron; copperas in crystals on the Des Moines, above the mouth of Saap and elsewhere, *pyrite*, blende.

Fort Dodge.—*Celestite.*

Makoqueta.—Hematite.

New Galena.—Octahedral galenite, anglesite.

MISSOURI.

Birmingham.—Limonite.

Jefferson Co., at Valle's diggings.—*Galenite, cerussite*, anglesite, calamine, chalcopyrite, malachite, azurite, witherite.

Mine a Burton.—*Galenite, cerussite, anglesite, barite*, calcite.

Deep Diggings.—Carbonate of copper, *cerussite* in crystals, and manganese ore.

Madison Co.—Wolframite.

Mine la Motte.—*Galenite!* malachite, *earthy cobalt* and *nickel*, bog manganese, sulphuret of iron and nickel, *cerussite*, caledonite, plumbogummite, wolframite, *siegenite*, smaltite.

St. Francis River.—Wolframite.

Perry's Diggings, and elsewhere.—Galenite, etc.

Forty miles west of the Mississippi and ninety south of St. Louis, the iron mountains, specular iron, limonite; 10 m. east of Ironton, wolframite, tungstite.

ARKANSAS.

Batesville.—In bed of White R., some miles above Batesville, gold.

Green Co.—Near Gainesville, lignite.

Hot Springs Co.—At Hot Springs, thuringite; Magnet Cove, *brookite! schorlomite*, *elæolite*, magnetite, quartz, green coccolite, garnet, apatite, *perowskite*, rutile, ripidolite, thomsonite (ozarkite).

Independence Co.—Lafferay Creek, psilomelane.

Lawrence Co.—Hoppe, Bath, and Koch mines, *smithsonite*, dolomite, galenite; nitre.

Marion Co.—Wood's mine, smithsonite, hydrozincite (marionite), galenite; Poke bayou, *braunite?*

Ouachita Springs.—*Quartz!* whetstones.

Pulaski Co.—Kellogg mine, 10 m. north of Little Rock, *tetrahedrite*, *tennantite*, nacrite, galenite, blende, quartz.

CALIFORNIA.

The principal *gold mines* of California are in Tulare, Fresno, Mariposa, Tuolumne, Calaveras, El Dorado, Placer, Nevada, Yuba, Sierra, Butte, Plumas, Shasta, Siskiyou, and Del Norte counties, although gold is found in almost every county of the State. The gold occurs in quartz, associated with sulphids of iron, copper, zinc, and lead; in Calaveras and Tuolomne counties, at the Mellones, Stanislaus, Golden Rule, and Rawhide mines, associated with tellurids of gold and silver; it is also largely obtained from placer diggings, and further it is found in beach washings in Del Norte and Klamath counties.

The *copper mines* are principally at or near Copperopolis, in Calaveras county; near Genesee Valley, in Plumas county; near Low Divide, in Del Norte county; on the north fork of Smith's River; at Soledad, in Los Angeles county.

The *mercury mines* are at or near New Almaden and North Almaden, in Santa Clara county; at New Idria and San Carlos, Monterey county; in San Luis Obispo county; at Pioneer mine and other localities in Lake county; in Santa Barbara county.

Alpine Co.—Morning Star mine, *enargite*, stephanite, polybasite, barite, quartz, pyrite.

Amador Co.—At Volcano, chalcedony, *hyalite*.

Alameda Co.—Diabolo Range, magnesite.

Butte Co.—Cherokee Flat, *diamond*.

Calaveras Co.—Copperopolis, *chalcopyrite*, malachite, *azurite*, *serpentine*, *picrolite*, native copper. near Murphy's, jasper, opal; albite, with gold and pyrite; Mellones mine, *calaverite*, *petzite*.

Contra-Casta Co.—San Antonio, chalcedony.

Del Norte Co.—Crescent City, agate, carnelian; Low Divide, chalcopyrite, bornite, malachite; on the coast, iridosmine, platinum.

El Dorado Co.—Pilot Hill, chalcopyrite; near Georgetown, hessite, from placer diggings; Roger's Claim, Hope Valley, *grossular garnet*, in copper ore; Coloma, *chromite;* Spanish Dry Diggings, *gold*.

Fresno Co.—Chowchillas, *andalusite*.

Ingo Co.—Ingo district, *galenite*, *cerussite*, dolomite, *barite*, atacamite, calcite, *grossular garnet!*

Lake Co.—Borax Lake, *borax!* boric acid, *glauberite;* Pioneer mine, cinnabar, native mercury, selenid of mercury; near the Geysers, sulphur, hyalite.

Los Angeles Co.—Near Santa Anna River, *anhydrite;* William's Pass, chalcedony; Soledad mines, chalcopyrite, *garnet*, gypsum; Mountain Meadows, garnet, in copper ore.

Mariposa Co.—Chalcopyrite; Centreville, cinnabar; Pine Tree mine, tetrahedrite; Burns Creek, limonite; Geyer Gulch, pyrophyllite; La Victoria mine, *azurite!* near Coulterville, *cinnabar*, *gold*.

Mono Co.—Partzite.

Monterey Co.—Alisal Mine, arsenic; near Paneches, chalcedony; New Idria mine, cinnabar; near New Idria, chromite, zaratite, chrome garnet; near Pachecos Pass, stibnite.

Nevada Co.—Grass Valley, *gold!* in quartz veins, with pyrite, chalcopyrite, blende, mispickel, galenite, *quartz*, biotite; near Truckee Pass, gypsum; Excelsior Mine, molybdenite, with molybdite and gold; Sweet Land, pyrolusite.

Placer Co.—Miners' Ravine, *epidote!* with *quartz*, *gold*.

Plumas Co.—Genesee Valley, chalcopyrite; Hope mines, *bornite*, sulphur.

Santa Barbara Co.—San Amedio Cañon, stibnite, asphaltum, bitumen, maltha, petroleum, cinnabar, iodid of mercury; Santa Clara River, sulphur.

San Diego Co.—Carisso Creek, gypsum; San Isabel, tourmaline, orthoclase, garnet.

San Francisco Co.—Red Island, pyrolusite and manganese ores.

Santa Clara Co.—New Almaden, *cinnabar*, *calcite*, *aragonite*, serpentine, chrysolite, quartz; North Almaden, chromite; Mt. Diabolo Range, magnesite.

San Luis Obispo Co.—Asphaltum, cinnabar.

San Bernardino Co.—Colorado River, agate, trona; Temescal, cassiterite Russ District, galenite, cerussite; Francis mine, cerargyrite.

Shasta Co.—Near Shasta City, hematite, in large masses.

Siskiyou Co.—Surprise Valley, selenite, in large slabs

Sonoma Co.—Actinolite, garnets.

Tulare Co.—Near Visalia, magnesite, asphaltum.

Tuolumne Co.—Tourmaline, tremolite; Sonora, *graphite;* York Tent, chromite; Golden Rule mine, *petzite*, *calaverite*, altaite, hessite, magnesite, tetrahedrite, gold; Whiskey Hill, *gold!*

Trinity Co.—Cassiterite, a single specimen found.

LOWER CALIFORNIA.

La Paz.—Cuproscheelite. Loretto.—Natrolite, siderite, selenite.

NEVADA.

Carson Valley.—Chrysolite.

Churchill Co.—Near Ragtown, *gay-lussite*, trona, common salt.

Comstock Lode.—Gold, *native silver*, *argentite*, *stephanite*, *polybasite*, pyrargyrite, proustite, tetrahedrite, cerargyrite, pyrite, chalcopyrite, galenite, blende, pyromorphite, arsenical antimony, arsenolite, quartz, calcite, gypsum, cerussite, cuprite, wulfenite, amethyst, küstelite.

Esmeralda Co.—Alum, 12 m. north of Silver Creek; at Aurora, fluorite, stibnite; near Mono Lake, native copper and cuprite, obsidian; Columbus district, borate of lime; Walker Lake, gypsum, hematite; Silver Peak, *salt*, saltpetre, sulphur, silver ores.

Humboldt District.—Sheba mine, *native silver*, *jamesonite*, stibnite, *tetrahedrite*, proustite, blende, cerussite, calcite, bournonite, pyrite, galenite, malachite, xanthocone (?).

Mammoth District.—*Orthoclase*, turquois, *hübnerite*, scheelite.

Reese River District.—Native silver, *proustite*, *pyrargyrite*, stephanite, blende, polybasite, rhodochrosite, embolite, *tetrahedrite!* cerargyrite, embolite.

San Antonia.—Belmont mine, stetefeldtite.

Six Mile Cañon.—*Selenite.*

Ormsby Co.—W. of Carson, *epidote.*

Storey Co.—Alum, natrolite, scolezite.

ARIZONA.

On and near the Colorado, gold, silver, and copper mines; at Bill Williams's Fork, chrysocolla, malachite, atacamite, brochantite; Dayton Lode, gold, fluorite, cerargyrite; Skinner Lode, octahedral fluorite; at various places in the southern part of the territory, silver and copper mines, Heintzelmann mine, *stromeyerite*, chalcocite, tetrahedrite, atacamite.

OREGON.

Gold is obtained from beach washings on the southern coast; quartz mines and placer mines in the Josephine district; also on the Powder, Burnt, and John Day's rivers, and other places in eastern Oregon; platinum, iridosmine, on the Rogue River, at Port Orford, and Cape Blanco.

IDAHO.

In the Owyhee, Boise, and Flint districts, *gold*, also extensive silver mines; Poorman Lode, *cerargyrite! proustite*, *pyrargyrite! native silver*, *gold*, pyromorphite, quartz, malachite; polybasite; on Jordan Creek, stream tin; Rising Star mine, *stephanite*, *argentite*, pyrargyrite.

COLORADO.

The principal gold mines of Colorado are in Boulder, Gilpin, Clear Creek, and Jefferson Cos., on a line of country a few miles W. of Denver, extending from Long's Peak to Pike's Peak. A large portion of the gold is associated with veins of pyrite and chalcopyrite; silver and lead mines are at and near Georgetown, Clear Creek Co., and to the westward in Summit Co on Snake and Swan rivers; Willis Gulch, near Black Hawk, *enargite* with pyrite, fluorite, scorodite?

CANADA.

CANADA EAST.

Abercrombie.—Labradorite.
Bay St. Paul.—*Menaccanite!* apatite, allanite, rutile (or brookite?).
Aubert.—Gold, iridosmine, platinum.
Bolton.—*Chromite*, *magnesite*, serpentine, picrolite, steatite, bitter spar, wad.
Boucherville.—*Augite* in trap.
Brome.—*Magnetite*, chalcopyrite, *sphene*, menaccanite, phyllite, sodalite, cancrinite, galenite, chloritoid.
Chambly.—Analcime, chabazite and calcite in trachyte, *menaccanite*.
Chateau Richer.—*Labradorite*, *hypersthene*, andesite.
Daillebout.—Blue spinel with clintonite.
Grenville.—*Tabular spar*, *sphene*, idocrase, calcite, pyroxene, steatite (rensselaerite), *garnet* (cinnamon-stone), *zircon*, *graphite*, *scapolite*.
Ham.—Chromite in serpentine, diallage, *antimony! senarmontite! kermesite*, *valentinite*, stibnite.
Inverness.—*Variegated copper*.
Lake St. Francis.—*Andalusite* in mica slate.
Landsdowne.—*Barite*.
Leeds.—Dolomite, chalcopyrite, gold, *chloritoid*.
Mille Isles.—*Labradorite!* menaccanite, hypersthene, andesite, *zircon*.
Montreal.—*Calcite*, *augite*, sphene in trap, chrysolite, natrolite.
Morin.—*Sphene*, *apatite*, *labradorite*.
Orford.—White garnet, *chrome garnet*, *millerite*, serpentine.
Ottawa.—*Pyroxene*.
Polton.—Chromite, *steatite*, serpentine, *amianthus*.
Rougemont Mts.—Augite in trap.
Sherbrooke.—At Suffield mine, *albite! native silver*, argentite, chalcopyrite, blende.
St. Armand.—Micaceous iron ore with quartz, epidote.
St. François Beauce.—Gold, platinum, iridosmine, ilmenite, magnetite, serpentine, chromite soapstone, barite.
St. Jerome.—*Sphene*, *apatite*, *chondrodite*, *phlogopite*, *tourmaline*, *zircon* molybdenite, *magnetic pyrites*.
St. Norbert.—Amethyst in greenstone.
Stukeley.—Serpentine, *verd-antique!* schiller spar.
Sutton.—*Magnetite* in fine crystals, *specular iron*, *rutile*, dolomite, *magnesite*, chromiferous *talc*, bitter spar, steatite.
Upton.—Chalcopyrite, malachite, calcite.
Vaudreuil.—Limonite, vivianite.
Yamaska.—Sphene in trap.

CANADA WEST.

Balsam Lake.—*Molybdenite*, scapolite, quartz, pyroxene, pyrite.
Brantford.—Sulphuric acid spring (4·2 parts of pure sulphuric acid in 1000).
Bathurst.—Barite, *black tourmaline*, *perthite* (orthoclase), *peristerite* (albite), *bytownite*, pyroxene, *wilsonite*.
Brome.—Magnetite.
Bruce Mines.—*Calcite*, dolomite, quartz, chalcopyrite.
Burgess.—*Pyroxene*, albite, *mica*, *sapphire*, sphene, chalcopyrite, *apatite*, *black spinel!* spodumene (in a boulder), serpentine.
Bytown.—*Calcite*, *bytownite*, chondrodite, spinel.
Cape Ipperwash, Lake Huron.—Oxalite in shales.
Clarendon.—*Idocrase*.
Dalhousie.—Hornblende, dolomite.
Drummond.—Labradorite.
Elmsley.—Pyroxene, sphene, feldspar, *tourmaline*, apatite.
Fitzroy.—Amber, brown *tourmaline* in quartz.

Gœtineau River, Blasdell's Mills.—Calcite apatite, tourmaline, hornblende, pyroxene.

Grand Calumet Island.—*Apatite, phlogopite! pyroxene!* sphene, *idocrase!!* serpentine, tremolite, *scapolite*, brown and black *tourmaline!* pyrite, loganite.

High Falls of the Madawaska.—*Pyroxene!* hornblende.

Hull.—*Magnetite*, garnet, graphite.

Hunterstown.—*Scapolite, sphene*, idocrase, garnet, *brown tourmaline!*

Huntingdon.—*Calcite!*

Inniskillen.—Petroleum.

Kingston.—*Celestite.*

Lac des Chats, Island Portage.—*Brown tourmaline!* pyrite, calcite, quartz.

Lanark.—Raphilite (hornblende), serpentine, asbestus.

Landsdown.—*Barite!* vein 27 in. wide, and fine crystals.

Madoc.—Magnetite.

Marmora.—Magnetite, chalcolite, garnet, epsomite, specular iron.

Maimanse.—*Pitchblende* (coracite).

McNab.—Specular iron, barite.

Michipicoten Island, Lake Superior.—*Domeykite, niccolite, genthite.*

Newborough.—*Chondrodite*, graphite.

South Crosby.—Chondrodite in limestone, magnetite.

St. Adele.—Chondrodite in limestone.

St. Ignace Island.—*Calcite*, native copper.

Sydenham.—Celestite.

Terrace Cove, Lake Superior.—Molybdenite.

Wallace Mine, Lake Huron.—*Specular iron*, nickel ore, nickel vitriol.

NEW BRUNSWICK.*

Albert Co.—Hopewell, gypsum; Albert mines, coal (albertite); Shepody Mountain, alunite in clay, calcite, iron pyrites, *manganite*, psilomelane, *pyrolusite.*

Carleton Co.—Woodstock, chalcopyrite, hematite, limonite, wad.

Charlotte Co.—Campobello, at Welchpool, blende, chalcopyrite, bornite, galenite, pyrite; at head of Harbor de Lute, galenite; Deer Island, on west side, calcite, magnetite, quartz crystals; Digdignash River, on west side of entrance, *calcite!* (in conglomerate), chalcedony; at Rolling Dam, graphite; Grandmanan, between Northern Head and Dark Harbor, agate, amethyst, *apophyllite, calcite*, hematite, heulandite, jasper, magnetite, natrolite, *stilbite;* at Whale Cove, *calcite!* heulandite, laumontite, stilbite, *semi-opal!* Wagaguadavic River, at entrance, azurite, chalcopyrite in veins, malachite.

Gloucester Co.—Tete-a-Gouche River, eight miles from Bathurst, chalcopyrite (mined), *oxyd of manganese!!* formerly mined.

Kings Co.—Sussex, near Cloat's mills, on road to Belleisle, argentiferous galenite; one mile north of Baxter's Inn, *specular iron* in crystals, limonite; on Capt. McCready's farm, *selenite!!*

Restigouche Co.—Bolledune Point, *calcite! serpentine, verd-antique;* Dalhousie, agate, carnelian.

Saint John Co.—Black River, on coast, calcite, chlorite, chalcopyrite, *hematite!* Brandy Brook, epidote, *hornblende*, quartz crystals; Carleton, near Falls, calcite; Chance Harbor, *calcite* in quartz veins, chlorite in argillaceous and talcose slate; Little Dipper Harbor, on west side, in greenstone, amethyst, barite, quartz crystals; Moosepath, feldspar, hornblende, muscovite, black tourmaline; Musquash, on east side harbor, copperas, graphite, pyrite; at Shannon's, chrysolite, serpentine; east side of Musquash, *quartz crystals!;* Portland, at the Falls, graphite; at Fort Howe Hill, *calcite*, graphite; Crow's Nest, asbestus, *chrysolite*, magnetite, *serpentine*, steatite; Lily Lake, white augite? chrysolite, graphite, serpentine, steatite, talc; How's Road, two miles out, epidote (in syenite), steatite in limestone, *tremolite;* Drury's Cove, graphite, pyrite, pyrallolite? indurated talc; Quaco, at Lighthouse Point, large bed oxyd of manganese; Sheldon's Point, actinolite, asbestus, calcite, *epidote*, malachite, specular iron; Cape Spencer, asbestus, calcite, chlorite, *specular iron* (in crystals); Westbeach, at east end, on Evans' farm, chlorite, talc, *quartz crystals;* half a mile west, chlorite, chalcopyrite, magnesite (vein), magnetite; Point Wolf and Salmon River, asbestus, chlorite, chrysocolla, chalcopyrite, bornite, pyrite.

Victoria Co.—Tabique River, *agate, carnelian*, jasper; at mouth, south side, galenite; at mouth of Wapskanegan, gypsum, salt spring; three miles above, stalactites (abundant); Quisabis River, blue phosphate of iron, in clay.

---

* For a more complete list of localities in New Brunswick, Nova Scotia, and Newfoundland, see catalogue by O. C. Marsh, Am. J. Sci., II. xxxv. 210, 1863.

Westmoreland Co.—Bellevue, pyrite; Dorcester, on Taylor's farm, cannel coal; clay iron stone; on Ayres's farm, asphaltum, petroleum spring; Grandlance, apatite, selenite (in large crystals); Memramcook, coal (albertite); Shediac, four miles up Scadoue River, coal.

York Co.—Near Fredericton, stibnite, jamesonite, berthierite; Pokiock River, stibnite, *tin pyrite?* in granite (rare).

NOVA SCOTIA.

Annapolis Co.—Chute's Cove, *apophyllite*, natrolite; Gates's Mountain, analcite, magnetite, *mesolite ! natrolite*, stilbite; Martial's Cove, *analcite !* chabazite, *heulandite*; Moose River, beds of magnetite; Nictau River, at the Falls, bed of hematite; Paradise River, black tourmaline, *smoky quartz ! !*; Port George, faröelite, laumontite, mesolite, stilbite; east of Port George, on coast, apophyllite containing gyrolite; Peter's Point, west side of Stonock's Brook, *apophyllite !* calcite, heulandite, *laumontite !* (abundant), native copper, stilbite; St. Croix Cove, chabazite, heulandite.

Colchester Co.—Five Islands, East River, *barite !* calcite, dolomite (ankerite), hematite, chalcopyrite; Indian Point, malachite, magnetite, red copper, tetrahedrite; Pinnacle Islands, *analcite*, calcite, *chabazite !* natrolite, siliceous sinter; Londonderry, on branch of Great Village River, *barite*, ankerite, hematite, limonite, magnetite; Cook's Brook, ankerite, hematite; Martin's Brook, hematite, limonite; at Folly River, below Falls, ankerite, pyrite; on high land, east of river, ankerite, hematite, limonite; on Archibald's land, ankerite, *barite*, hematite; Salmon River, south branch of, chalcopyrite, hematite; Shubenacadie River, anhydrite, calcite, *barite*, hematite, oxyd of manganese; at the Canal, pyrite; Stewiacke River, barite (in limestone).

Cumberland Co. — Cape Chiegnecto, barite; Cape D'Or, *analcite*, *apophyllite ! !* chabazite, faröelite, laumontite, *mesolite*, malachite, *natrolite*, *native copper*, obsidian, red copper (rare), vivianite (rare); Horse-shoe Cove, east side of Cape D'Or, analcite, calcite, stilbite; Isle Haute, south side, analcite, *apophyllite ! !* calcite, *heulandite ! !* natrolite, mesolite, *stilbite !* Joggins, coal, hematite, limonite; malachite and tetrahedrite at Seaman's Brook; Partridge Island, analcite, *apophyllite !* (rare), *amethyst !* agate, apatite (rare), *calcite ! !* chabazite (acadiolite), chalcedony, cat's-eye (rare), gypsum, hematite, *heulandite !* magnetite, *stilbite ! !*; Swan's Creek, west side, near the Point, calcite, gypsum, *heulandite*, pyrite; east side, at Wasson's Bluff and vicinity, *analcite ! ! apophyllite !* (rare), *calcite*, *chabazite ! !* (acadiolite), gypsum, *heulandite ! ! natrolite !* siliceous sinter; Two Islands, moss agate, analcite, calcite, chabazite, *heulandite*; McKay's Head, analcite, calcite, heulandite, *siliceous sinter !*

Digby Co.—Brier Island, native copper, in trap; Digby Neck, Sandy Cove and vicinity, *agate*, *amethyst*, *calcite*, *chabazite*, *hematite ! laumontite* (abundant), magnetite, *stilbite*, quartz crystals; Gulliver's Hole, *magnetite*, *stilbite !*; Mink Cove, amethyst, *chabazite !* quartz crystals; Nichol's Mountain, south side, *amethyst*, *magnetite !*; William's Brook, near source, *chabazite* (green), heulandite, stilbite, quartz crystals.

Guysboro' Co.—Cape Canseau, *andalusite*.

Halifax Co.—Gay's river, galenite in limestone; southwest of Halifax, garnet, staurolite, tourmaline; Tangier, *gold !* in quartz veins in clay slate, associated with auriferous pyrites, galenite, hematite, mispickel, and magnetite; gold has also been found in the same formation, at Country Harbor, Fort Clarence, Isaac's Harbor, Indian Harbor, Laidlow's farm, Lawrencetown, Sherbrooke, Salmon River, Wine Cove, and other places.

Hants Co.—Cheverie, oxyd of manganese (in limestone); Petite River, gypsum, oxyd of manganese; Windsor, calcite, cryptomorphite (boronatrocalcite), howlite, glauber salt. The last three minerals are found in beds of gypsum.

Kings Co.—Black Rock, centrallassite, cerinite, cyanolite; a few miles east of Black Rock, prehnite? *stilbite !*; Cape Blomidon, on the coast between the cape and Cape Split, the following minerals occur in many places (some of the best localities are nearly opposite Cape Sharp): *analcite ! ! agate*, *amethyst ! apophyllite !* calcite, chalcedony, chabazite, gmelinite (ledererite), hematite, *heulandite !* laumontite, magnetite, malachite, *mesolite*, native copper (rare), *natrolite !* psilomelane, *stilbite !* thomsonite, faröelite, *quartz*; North Mountains, amethyst, bloodstone (rare), *ferruginous quartz*, *mesolite* (in soil); Long Point, five miles west of Black Rock, *heulandite*, *laumontite ! ! stilbite ! !*; Morden, *apophyllite*, *mordenite*; Scot's Bay, *agate*, amethyst, *chalcedony*, mesolite, natrolite; Woodworth's Cove, a few miles west of Scot's Bay, *agate ! chalcedony ! jasper*.

Lunenburg Co.—Chester, Gold River, gold in quartz, pyrite, mispickel; Cape la Have, pyrite; The "Oveus," *gold*, pyrite, *mispickel !* Petite River, gold in slate.

Pictou Co.—Pictou, *jet*, oxyd of manganese, limonite; at Roder's Hill, six miles west of Pictou, barite; on Carribou River, gray copper and malachite in lignite; at Albion mines, coal. limonite East River, limonite.

Queens Co.—Westfield, gold in quartz, pyrite, mispickel; Five Rivers, near Big Fall, gold in quartz, pyrite, mispickel, limonite.

RICHMOND Co.—West of Plaister Cove, barite and calcite in sandstone; nearer the Cove, calcite, *fluorite* (blue), siderite.

SHELBURNE Co.—Shelburne, near mouth of harbor, garnets (in gneiss); near the town, rose quartz; at Jordan and Sable River, *staurolite* (abundant), schiller spar.

SYDNEY Co.—Hills east of Lochaber Lake, pyrite, chalcopyrite, siderite, hematite; Morristown, epidote in trap, gypsum.

YARMOUTH Co.—Cream Pot, above Cranberry Hill, gold in quartz, pyrite; Cat Rock, Fouchu Point, asbestus, calcite.

NEWFOUNDLAND.

ANTONY'S ISLAND.—*Pyrite.*

CATALINA HARBOR.—On the shore, *pyrite!*

CHALKY HILL.—*Feldspar.*

COPPER ISLAND, one of the Wadham group.—*Chalcopyrite.*

CONCEPTION BAY.—On the shore south of Brigus, bornite and gray copper in trap.

BAY OF ISLANDS.—Southern shore, *pyrite* in slate.

LAWN.—*Galenite, cerargyrite, proustite, argentite.*

PLACENTIA BAY.—At La Manche, two miles eastward of Little Southern Harbor, *galenite!*; on the opposite side of the isthmus from Placentia Bay, barite, in a large vein, occasionally accompanied by chalcopyrite.

SHOAL BAY.—South of St. John's, chalcopyrite.

TRINITY BAY.—Western extremity, barite.

HARBOR GREAT ST. LAWRENCE.—West side, fluorite, galenite.

SUPPLEMENT.

This supplement contains descriptions of some species imperfectly known, and notices of new or described species which came to hand too late to be inserted in the preceding part of this work. The numbers affixed to the species indicate their places in the system.

Æschynite (480, p. 522). Mean of four closely agreeing analyses by Marignac (Bib. Univ Genève, Aug. 25, 1867, p. 286):

$\ddot{\bar{\text{C}}}\text{b}$, $\ddot{\text{Ti}}$	$\ddot{\text{Sn}}$	$\ddot{\text{Th}}$	$\dot{\text{Ce}}$	$\dot{\text{La}}$, $\dot{\text{Di}}$	$\dot{\text{Y}}$	$\dot{\text{Fe}}$	$\dot{\text{Ca}}$	ign.
51·45	0·18	15·75	18·49	5·60	1·12	3·17	2·75	1·07=99·58.

G.=5·23. The amount of metallic acids varied between 51·15 and 51·75. Analyses of the metallic acid gave the relation, $\ddot{\bar{\text{C}}}\text{b}$ 29·31, $\ddot{\text{Ti}}$ 22·14, differing materially from Hermann's results. Marignac, having previously examined the acids of euxenite (see p. 522), concludes that the relation between the metallic acids is the same as in æschynite, and that these two minerals differ mainly in the character of the bases they contain; and that both may be represented by the general formula $5\,\dot{\text{R}}\,\ddot{\text{Ti}}+2\,\dot{\text{R}}^{3}\,\ddot{\bar{\text{C}}}\text{b}$.

Agnesite. Carbonate of Bismuth *W. Macgregor*, Sowerby's English Min., *Beud.*, Tr., ii. 3[illegible], 1832; Agnesite *B. & M.* Min., 591, 1852. An earthy steatite-like mineral from St. Agnes in Cornwall, having G.=4·31, made by Macgregor to consist of $\ddot{\text{C}}$ 51·3, $\ddot{\bar{\text{B}}}\text{i}$ 28·8, $\ddot{\bar{\text{F}}}\text{e}$ 2·1, $\ddot{\bar{\text{A}}}\text{l}$ 7·5, $\dddot{\text{Si}}$ 6·7, $\dot{\bar{\text{H}}}$ 3·6=100; which result is pronounced by Beudant as probably "quelque grande erreur," and so proved by Thomson (Min., ii. 594), who states, after personal trials, that it did "*not* effervesce with acids, and contained only a trace of bismuth"; and also by Greg and Lettsom, who examined a specimen in the late Mr. Allan's collection, from Mr. Macgregor, with the same result as to effervescence, and say that it may be an impure bismuth ochre. Allan appears to have thought it unworthy of a place in his edition of Phillips' Mineralogy (1837), and does not even allude to it under bismuth ochre.

Altaite (48, p. 44). This rare species has been identified at the Stanislaus mine, Cal., and F. A. Genth has also observed it in minute quantities associated with petzite at the Golden Rule mine, Cal. (Am. J. Sci., II. xlv. 311). The mineral from the former locality is tin-white, with a yellowish tinge, tarnishing to bronze-yellow; streak gray; with H.=3, and has a distinctly cubic cleavage. Composition, after deducting in 1, 1·03 p. c., and in 2, 1·96 of quartz:

	Te	Pb	Ag	Au
1.	37·31	60·71	1·17	0·26=99·45.
2.	[37·00]	47·84	11·30	3·86=100·00.

No. 1 is the first complete analysis of this species, and confirms the assumption of Rose that it is a compound analogous to hessite. Dr. Genth calculates No. 1 to contain 99·25 p. c. of altaite and 2·20 of hessite; and No. 2, 77·42 altaite, and 23·11 p. c. hessite. An earlier result on another specimen obtained by Genth, after separating carbonates and excluding 8 p. c. free gold, and 3·45 quartz, gave Te (37·14), Ag 44·49, Pb 18·37=100·00. This may represent 70·85 hessite, and 29·26 altaite. The material appeared to be pure, but Genth states that further investigation is needed to ascertain whether there is a tellurid of silver, or tellurid of silver and lead, which has a white color and cubic cleavage.

Amphibole (247, p. 232). Compact asbestus from Bolton, Mass., afforded T. Petersen (Jahresb for 1866, 924, 1868):

$\dddot{\text{Si}}$ 58·80 $\ddot{\bar{\text{A}}}\text{l}$ *tr.* $\dot{\text{F}}\text{e}$ 3·05 $\dot{\text{Mg}}$ 22·23 $\dot{\text{Ca}}$ 16·47 $\dot{\bar{\text{H}}}$ *tr.*=100·55. G.=3·007.

The formulas on the new system for aluminous pyroxene and amphibole, pp. 207, 208, become f the Greek-lettered symbol be used also for the silica, $(\gamma\ddot{\mathrm{Si}}_2, \beta\ddot{\bar{\mathrm{Al}}}_2)\,\Theta|\Theta_2|\,\bar{\mathrm{R}}$.

ANDALUSITE (322, p. 371). The chiastolite of Lancaster, Mass., afforded T. Petersen (Jahresb 1866, 921):

$\ddot{\mathrm{Si}}$ 41·95 $\ddot{\bar{\mathrm{Al}}}$ 48·60 $\ddot{\bar{\mathrm{Fe}}}$ 9·30 $\dot{\mathrm{Ca}}$ 0·41=100·26. G.=2·928.

ANORTHITE (310, p. 337). *Tankite* is referred to anorthite on p. 337, on the authority of Descloizeaux, who has found them to have the same forms of crystals and angles (Mem. Soc. Min. St Pet, II. ii. 1867). Descloizeaux also publishes (l. c.) the following analyses of tankite by Pisani: $\ddot{\mathrm{Si}}$ 42·49, $\ddot{\bar{\mathrm{Al}}}$ 34·70, $\ddot{\bar{\mathrm{Fe}}}$ 0·74, $\dot{\mathrm{Mg}}$ 0·30, $\dot{\mathrm{Ca}}$ 15·82, $\dot{\mathrm{Na}}$, $\dot{\mathrm{Li}}$ 1·60, $\dot{\mathrm{K}}$ 0·63, $\dot{\mathrm{H}}$, F 4·80=101·08; whence the oxygen ratio, $\dot{\mathrm{R}}$, $\ddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, 1 : 3 : 4. The mineral is from the iron mines of Arendal, Norway, where it was originally obtained by Mr. Tank.

Anorthite crystals from the Juvenas meteorite have been measured by v. Lang (Pogg., cxxxiii. 188).

ARSENOPYRITE (94, p. 78). Von Zepharovich has measured crystals of this species, with the following results (Ber. Ak. Wien, lvi. i. 21, 1867):

From Œblarn, Styria	$I \wedge I$=111° 10′ 38″	1-ĭ ∧ 1-ĭ, top,=80° 16′ 25″
Freiberg, Sax.	" 111 27	
Breitenbrunn, Sax.	" 111 29	¼-ĭ ∧ ¼-ĭ, top,=151 36
Reichenstein, Silesia	" 111 30	
Eisenerz, Styria	" 111 40	
Joachimsthal	" 111 10	⅓-ĭ ∧ ⅓-ĭ, top,=136 30

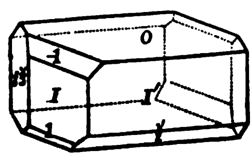
ATACAMITE (153, p. 121). The following are additional observations on this species:

Artif.—Field has shown (Phil. Mag., IV. xxiv. 123) that when an alkaline hypochlorite is added to a boiling solution of the sulphate, nitrate, or chlorid of copper, the latter being in excess, the precipitate produced has the formula $3\,\dot{\mathrm{Cu}}\,\dot{\mathrm{H}}+\mathrm{Cu\,Cl}\,\dot{\mathrm{H}}$. The same is formed when potash is added to an excess of chlorid of copper. If, in the first case given above, the time of ebullition is too short, the precipitate has the composition $3\,\dot{\mathrm{Cu}}\,\dot{\mathrm{H}}+\mathrm{Cu\,Cl}\,\dot{\mathrm{H}}+2\,\mathrm{aq}$. Field's analysis gave $\dot{\mathrm{Cu}}$ 49·85, Cu Cl 28·02, $\dot{\mathrm{H}}$ 22·13, agreeing very closely, as he observed, with that of Berthier (anal. 1) from Cobija, Bolivia. The formula requires $\dot{\mathrm{Cu}}$ 49·56, Cu Cl 28·01, $\dot{\mathrm{H}}$ 22·43=100. This is also the composition of botallackite. Field states also that atacamite is formed in Chili at a seashore locality by the action of salt in the soil on chalcopyrite.

Debray finds that crystals may be obtained by heating to 200° C., $\dot{\mathrm{Cu}}^3\,\dddot{\mathrm{N}}$ with a concentrated solution of common salt; or to 100° C., ammoniacal sulphate of copper with the same.

BABINGTONITE (242, p. 227). The small, black, brilliant crystals from Athol referred to babingtonite by Shepard (p. 228), do not afford very nearly the angles of that species. They are usually implanted on green epidote, and, although black, they appear, under a glass, to pass so gradually into the underlying mineral that the first impression is naturally that they are only a black variety of epidote. Yet they differ also from this species in angle. The author has attempted to make new measurements, but the crystals for the purpose were so minute ($\frac{1}{40}$ of an inch in length) that they require further study for satisfactory results. The author's figure and "approximate measurements" from the last edition of this work are consequently here added without modification, or even the change in the lettering that is required to bring the figure into parallelism with the figures of babingtonite. $O \wedge I$=90°–91°, $O \wedge I'$=85°, $O \wedge \frac{1}{2}'$=158° 20′, $I \wedge I'$=110° 30′ and 69° 30′, $I \wedge$ i-3̆=129°, $I' \wedge$ i-3̆=120° 30′, $O \wedge$ -1=135° 40′, $O \wedge$ 1=135° 30′, $O \wedge$ i-3̆=95° 30′, $I \wedge \frac{1}{2}$=95° 30′.

617



BARNHARDITE (79, p. 67). A specimen of this mineral from Bill Williams Fork, Arizona, found with metallic copper, cuprite, chalcocite, pyrite, chrysocolla, malachite, and brochantite, gave N. S. Higgins, according to Genth (Am. J. Sci., II. xlv. 319), S 28·96, Cu 50·41, Fe 20·44=99·81; showing a slight admixture with chalcocite.

BERYL (254, p. 245). The green beryl of Royalston, Mass., yielded on analysis by T. Petersen Jahresb. 1866, 925) $\ddot{\mathrm{Si}}$ 67·52, $\ddot{\bar{\mathrm{Al}}}$ 17·42, Be 14·35, $\ddot{\bar{\mathrm{Fe}}}$, $\dot{\mathrm{Ca}}$ *tr.*=99·29. G.=2·65.

BERZELIANITE (50, p. 46). According to A. E. Nordenskiöld (Œfv. Ak. Stockholm, 1866, 361, J. pr. Ch., cii. 456) berzelianite occurs at Skrikerum as a black to blackish-blue powder, disseminated through a coarse crystalline calcite, showing no traces of crystalline structure, but sometimes forming dendritic crusts. When in sufficient masses to be observed, it has a metallic lustre and silver-white fracture, the surface of which soon tarnishes. G.=6·71.

	Se	Cu	Ag	Fe	Tl
1.	39·85	53·14	4·73	0·54	0·38=98·64.
2.	38·74	52·15	8·50	0·54	*tr.*=99·74.

Nordenskiöld remarks that the varying percentage of the silver is possibly due to an admixture of eucairite, and that the amount of thallium in the analyses is probably too low.

BISMUTHAURITE or **BISMUTHIC GOLD** *Shep.*, Min., 304, 1857. A furnace product (Am. J. Sci., II xxiv. 112, 1867).

BOBIERRITE. Phosphate de Magnésie tribasique et hydraté *Bobierre*, Les Mondes, April 1868 691; Bobierrite *Dana* (523A).—Monoclinic; in six-sided prismatic forms. Crystals minute, and forming crystalline agglomerations, imbedded in guano, looking like white spots in the guano. Crystals colorless. Composition, according to Bobierre (l. c.), Mg^3P with water. It is insoluble in water, but easily soluble in acids without effervescence. Contains not a trace of lime.

From the guano of Mexillones, on the Peruvian Coast.

BOULANGERITE (122, p. 99). Found, according to v. Zepharovich, at Przibram in Bohemia, with jamesonite (Ber. Ak. Wien, lvi. 1867). He gives the following analyses:

		S	Sb	Pb	Fe
1. Eusebi vein,	*fib.*	18·77	26·81	54·42	*tr.*=100 E. Boricky.
2. " "	*comp.*	19·77	24·46	54·32	*tr.*=98·55 E. Boricky.
3. Adelberti "	"	18·89	21·87	57·69	0·84, Ag 0·25, Zn 0·47=100·01 Helmhacker.
4. " "	"	18·64	24·31	55·06	1·46=99·47 Boricky.
5. " "	*fib.*	18·47	24·17	55·96	Fe, Mn 0·08, Cu 0·22, Ag 0·84=99·74 Helml
6 " "	"	17·60	22·81	58·13	0 57=99 11 Boricky.
7. " "	*capil.*	17·95	22·91	57·28	1·35, Ag 0·06, Zn 0·34=99·89 Helmhacker.
8. " "	"	17·74	25·11	57·42	*tr.*=100 27 Boricky.
9. " "	*needles*	20·49	27·72	48·38	3·47=100·06 Boricky.

1, fine fibrous, G.=5·75; 2, subfibrous, G.=5 91; 3, compact, with subconchoidal fracture, G =5·877, associated with zinc-blende; 4, associated with a coarse granular to fibrous galenite, G =5 809; 5, found in nests in galenite, G.=5 69; 6, G.=6·08; 7, in short, felt-like, capillary crystals, with quartz and calcite; 9, associated with quartz, G.=5·52.

F. A. Genth obtained for boulangerite from Echo District, Union Co., Nevada (Am. J. Sci., II. xlv. 320, 1868), S 17·91, Sb 26·85, Pb 54·82, Ag 0·42=100. Occurs in indistinct acicular striated crystals, in white quartz.

BROCHANTITE (701, p. 664). F. A. Genth has found this mineral in minute crystals, showing the planes *I*, *i*-*i*, and 1-*i*, with the copper ores at Bill Williams Fork, Arizona. For analyses of specimen, mixed with atacamite, chrysocolla, etc., see Am. J. Sci., II. xlv. 321, 1868.

CALAVERITE *F. A. Genth*, Am. J. Sci., II. xlv. 314, 1868. (98A.) A new tellurid of gold, from the Stanislaus mine, Calaveras Co., Cal. It occurs massive, without crystalline structure; color bronze-yellow; streak yellowish-gray; brittle; fracture uneven, inclining to subconchoidal.

Composition.—$AuTe_4$=Te 55·53, Au 44·47. Analyses 1, 2, from 2 1·45 p. c. quartz deducted:

1.	Te 55·89	Au 40·70	Ag 3·52=100·11.
2.	[56·00]	40·92	3·08=100.

B.B. on charcoal burns with a bluish-green flame, yielding globules of very yellow gold. Dissolves in nitro-muriatic acid, with separation of chlorid of silver.

Calaverite is frequently associated with petzite, to which a portion of the silver in the analyses is attributed. In a comparison of the results of analyses of sylvanite from Transylvania, Dr. Genth makes the suggestion that the so-called "*gelberz*" (see anal. 8, 9, p. 82) is nothing else than impure calaverite.

CALCITE (715, p. 670). Vom Rath, in his elaborate papers on calcite (Pogg., cxxxii.) mentions besides the planes given from him on pp. 673, 674, 676, the scalenohedron $-\frac{2}{3}\frac{3}{2}^{3}$, which has for the angle over its longer edge, 155° 43′, shorter edge 101° 35′, middle edge, 114° 54′; and the rhombohedron $-\frac{3}{8}$, having $R \wedge R$=142° 56′, and $O \wedge R$=158° 28′.

Cassiterite (192, p. 157). T. Petersen (Jahresb. 1866, 920, 1868) found in the tin-stone of Zinnwald, ($\frac{3}{8}$) $\ddot{\mathrm{Sn}}$ 88·04, $\dddot{\overline{\mathrm{Fe}}}$ 4·49, $\dddot{\overline{\mathrm{Mn}}}$ 2·78, $\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$ 4·30=99·61.

Catlinite C. T. Jackson (Am. J. Sci., xxxv. 388) thus named the red clay from the Coteau de Prairies, in the Upper Missouri region, where it forms a bed of considerable extent, referred by Hayden to the Cretaceous formation. Analyses:

$\ddot{\mathrm{Si}}$	$\dddot{\overline{\mathrm{Al}}}$	$\dddot{\overline{\mathrm{Fe}}}$	$\dddot{\overline{\mathrm{Mn}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}\,\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$	
56·11	17·31	6·96	—	0·20	2·16	12·48	4·59	Thomson.
48·2	28·2	5·0	0·6	6·0	2·6	—	8·4	Jackson.

It is a rock and not a definite mineral species.

Centrallassite *How*, Ed. N. Phil. J., x. 84, 1859. (341A.) Radiated massive, the fibres or columns lamellar and separable; H.=3·5; G.=2·45–2·46; lustre pearly; color white or yellowish-white; thin laminæ transparent; graduating into an opaque white variety, subresinous in lustre; brittle. The mineral was found in a nodule from amygdaloid, near Black Rock, Bay of Fundy, and constituted the portion between a thin outer layer (named by How *cerinite*) and an inner bluish mass, called by him *cyanolite*. How obtained, as a mean of two analyses (l. c.):

$\ddot{\mathrm{Si}}$ 58·86 $\dddot{\overline{\mathrm{Al}}}$ 1·14 $\dot{\mathrm{Mg}}$ 0·16 $\dot{\mathrm{Ca}}$ 27·92 $\dot{\mathrm{K}}$ 0·59 $\dot{\mathrm{H}}$ 11·42.

B.B. fuses easily, with spirting, to an opaque glass; a clear bead with the fluxes.
It is near okenite in composition.

Chamoisite (469, p. 511). An oölitic mineral, near chamoisite, described by Pouillon Boblaye (Mem. Mus., xv.), has been called *Bavalite*. It has H. about 4; G.=3·99, Delesse; color greenish-black, bluish, or grayish; powder greenish-gray or black, to reddish-brown; and B.B. fusible with difficulty to a black magnetic scoria. Analyses: 1, Berthier; 2, Delesse:

	$\ddot{\mathrm{Si}}$	$\dddot{\overline{\mathrm{Al}}}$	$\dddot{\overline{\mathrm{Cr}}}$	$\dddot{\overline{\mathrm{Fe}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$	C	Clay	
1. Quintin	11·0	13·3	0·3	48·8	23·4	—	—	—	3·2=100	Berthier.
2. "	6·50	7·50	0·50	65·45	13·25	0·45	4·85	1·30	0·20=100	Delesse.

Forms beds in old schistose rocks in different parts of Brittany, especially in the forest of Lorges, a locality that supplies furnaces at Pas near Quintin, in the vicinity of St. Brieuc, Dept. of Côtes-du-Nord; also at the Chapel St. Oudon, near Segré, Dept. of Maine-et-Loire; and elsewhere. Huot and others derive the name *bavalite* from Bavalon, a locality of it; but Descloizeaux says no such place exists in Brittany; but that a depression in the region where it is explored is called the *bas vallon*—an absurd origin for a name.

Chrysoberyl (191, p. 155). Frischman on twin crystals of chrysoberyl, Ber. Ak. München, 1867, i. 429.

Chrysolite (259, p. 256). A partially decomposed olivine, from Neurode in Silesia, afforded Rammelsberg (ZS. G., xix. 285) $\ddot{\mathrm{Si}}$ 34·97, $\dot{\mathrm{Fe}}$ 18·55, $\dot{\mathrm{Mg}}$ 36·00, $\dot{\mathrm{Ca}}$ 0·44, $\dddot{\overline{\mathrm{Al}}}$ 0·75, $\dot{\mathrm{H}}$ 6, magnetite 3·21=99·92.

Claudetite. Prismatic Arsenious Acid *F. Claudet*, Proc. Ch. Soc., 1868, Ch. News, xvii 128, 1868; Claudetite *Dana*. (221A.) Orthorhombic, and isomorphous with valentinite, while dimorphous with arsenolite. Observed in thin plates, resembling selenite. H.=2·5. G.=3·85. Lustre strongly pearly.

Composition $\mathrm{As\,O^3}$, as for arsenolite, being essentially pure arsenous acid. Claudet obtained in an analysis about 47 p. c. of this acid with other metallic substances as impurities.

Occurs in seams in an ore of arsenical pyrites, at the San Domingo mines, Portugal.

It heads the Valentinite group, p. 184.

Clausthalite (45, p. 42). For analysis of this mineral from Cacheuta, see under **Eucairite**, p. 798.

Columbite (474, p. 515). Hermann, in the J. pr. Ch., ciii. 127, sustains anew his views on ilmenic acid, and gives the following results of recent investigations:

	$\ddot{\bar{\text{E}}}\text{b}$	$\dddot{\bar{\text{Ta}}}$	$\dddot{\text{H}}$	$\ddot{\text{Sn}}$	$\dddot{\text{W}}$	$\dot{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$
1. Haddam	41·17	10·77	25·74	0·40	0·26	14·05	5·63	0·49=98·52.
2. Bodenmais	35·49	28·12	16·38	0·36	——	14·11	4·13	1·27, $\dot{\text{Cu}}$ 0·13=99·99
3. Greenland	38·27	0·56	39·78	*tr.*	——	16·54	5·00	0·06=100·16.

Hermann is here copied in making the metallic acids to contain 3 of oxygen. Analysis 1 is a revision of anal. 4, p. 517.

Hermann makes three varieties of columbite: (1) Tantalum-columbite, with density above 5·90. (2) Columbium-columbite, with G.=5·50–5·90. (3) Ilmenium-columbite, with G. below 5·50. He thus claims that the Greenland mineral is *ilmenium-columbite* (G.=5·40), while, according to the recent careful researches of Blomstrand (anal. 25, p. 518), it contains only columbic and tantalic acids.

Cosalite *F. A. Genth*, Am. J. Sci., II. xlv. 319. (112A.) Indistinctly crystalline, with longitudinal striations, apparently rhombic. Soft and brittle. Lustre metallic. Color lead-gray. Fracture uneven.

Composition 2 Pb S+Bi S_3=Sulphur 16·10, Bi 42·25, Pb 41·65=100. Analyses: 1 (after deducting 2·09 p. c. quartz); 2 (after deducting 26·83 p. c. quartz):

	S	As	Pb	Ag	Bi	Co
1.	15·59	3·07	37·72	2·48	39·06	2·41=100·33.
2.	15·64	5·37	33·99	2·81	37·48	4·22=99·51.

As cobaltite was associated with the mineral, Genth regards the Co and As as due to this species, and deducts them, making in anal. 1, 6·79 p. c. cobaltite, and in 2, 11·88 p. c., giving for 1, S 15·27, Bi 41·76, Pb 40·32, Ag 2·65; and for 2, S 15·23, Bi 42·77, Pb 38·79, Ag 3·21; corresponding with the formula 2 (Pb, Ag) S+Bi^2S^3, making the mineral a jamesonite in which the antimony is replaced by bismuth. B.B. cosalite reacts for sulphur, lead, and bismuth, and with soda on charcoal yields a minute globule of silver. Found associated with quartz and cobaltite in a silver mine at Cosala, Province of Sinaloa, Mexico.

Cryolite (164, p. 127). Crystals of cryolite have been described and figured by Websky (Jahrb. Min. 1867, 810). His measurements make the form triclinic. The general form of the crystals and the planes are as in f. 130. The following are his measured angles, using the lettering in that figure: $I \wedge I$=88° 3′ and 91° 57′, $O \wedge$ 1-ĭ, left,=124° 35′, $O \wedge$ 1-ī, front,=125° 54′—125° 57′, $O \wedge$ 1-ī, back,=125° 28′—125° 33′, $O \wedge I$, right,=90° 24′, $O \wedge I$, left, 90° 1′—90° 10′, and 89° 58′, I, right, $\wedge$ 1-ī, front,=124° 30′, I, left, $\wedge$ 1-ī, front,=124° 14′; I, right, $\wedge$ 1-ī, back,=126° 20′. Two kinds of twins are described: 1, composition-face *i*-ī; and 2, c.-face O.

Websky also describes the optical characters of the crystals.

Cyanolite *How*, Ed. N. Phil. J., x. 84, 1859. (341B.) Amorphous, of a bluish-gray color, little lustre, and nearly opaque; H.=4·5; G.=2·495; B.B. fuses only on the thin edges; gives clear beads with the fluxes. Two analyses by How afforded:

$\dddot{\text{Si}}$	$\dddot{\bar{\text{Al}}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
74·15	0·84	*tr.*	17·52	0·53	7·39=100·43.
72·52	1·24	*tr.*	18·19	0·61	6·91=99·47.

Probably the same mineral with centrallassite (p. 796), impure with much more silica; or it is chalcedony, impure with centrallassite. The name alludes to the color.

Domeykite (37, p. 36). Occurs in the mountain of Paracatas, between Cuatzamala and Tlachapa.

Enargite (132, p. 107). Occurs, according to E. W. Root (Am. J. Sci., II. xlv.), at the Morning Star mine, Alpine Co., Cal., both massive and in small, brilliant, black crystals, associated with pyrite, quartz, and menaccanite. H.=4; G.=4·34. Mean of two analyses, S 31·66, As 13·70, Sb 6·03, Fe, with trace $\ddot{\text{Ti}}$, 0·72, Cu 45·95, $\dddot{\text{Si}}$ 1·08=99·14.

Erlanite. Erlan *Breith.* Handb., 606. Supposed to be a rock.

Eucairite (42, p. 39). According to A. E. Nordenskiöld (Œfv. Ak. Stockholm, 1866, 361, a

J. pr. Ch., cii. 456), this species occurs in opaque silver-white to lead-gray grains in part disseminated in serpentine, sometimes with indications of cubic or octahedral planes. H.=2·5; G.=7·48—7·51. Analyses:

	Se	Cu	Ag	Fe	Tl
1.	——	24·86	42·57	0·35	*tr.*
2.	32·01	25·83	44·21	0·36	*tr.*

agreeing with the formula (Ɵu, Ag) Se or Ɵu Se + Ag Se.

Domeyko has examined the selenids from Cacheuta in the province of Mendoza, Chili (C. R., lxiii. 1064), and considers them to consist of mixtures or combinations of three selenids: (A) A compound analogous to eucairite; (B) a selenid of cobalt and iron; and (C) a selenid of lead. Analyses:

	Se	Ag	Cu	Fe	Co	Pb	$\dot{\mathrm{Pb}}\ddot{\mathrm{C}}$	Gangue
1.	30·00	21·00	1·80	2·20	0·70	43·50	——	——=99·2.
2.	22·40	20·85	12·91	3·10	1·26	6·80	32·68	=100.
3.	30·80	9·80	10·20	1·20	2·80	37·10	6·5	=98·4.
4.	——	3·73	13·80	3·35	1·97	21·30	15·25	7·40=——.
5.	23·60	——	——	0·80	——	57·80	10·90	3·50=98·6.

No. 1 had a bright bluish-gray color and metallic lustre, was somewhat porous, and occurred with silicate of copper and carbonate of lead, which last was separated before analysis. G.=6·8. No. 2 was similar. In 3 and 4 the silver is partly replaced by copper. No. 5 is almost pure selenid of lead. G.=7·6.

GANOMATITE *Breith.*, Char., 106, 1832. (Gänseköthigerz *Germ.*, Goose-dung Ore, Chenocoprolite, *Dana*, Min., 1st ed., 216, 1837.) The material thus named is in part an impure iron-sinter, containing some oxyd of cobalt, etc. That of Joachimsthal is a yellowish incrustation, occurring with smaltine. That of Andreasberg is a mixture of oxyds of antimony, arsenic, and iron, with a little arsenous acid (Ramm. Min. Ch., 993).

GERSDORFFITE (86, p. 72). Analyses of gersdorffite, having G.=5·49—5·65, from Craigmuir mine, Loch Fyne, Scotland, by D. Forbes (Phil. Mag., IV. xxxv. 181, 1868):

S	As	Ni	Co	Fe	Mn	Cu	Mg	Insol.
20·01	34·45	21·59	6·32	13·12	0·33	*tr.*	0·66	2·71=99·19.
19·75	35·84	23·16	6·64	11·02	0·33	*tr.*	0·66	2·60=100.

GEOMYRICITE (797, p. 739). The author learns further from L. Lesquereux (March 4, 1868) that, as existing species of the families *Populus*, *Myrica*, and *Laurus* are wax-bearing, wax may have been afforded to the Gesterwitz beds by the species, now fossil in that basin, *Cinnamomum Rossmässleri* Heer, *Gautiera lignitum* Web., *Laurus primigenia* and *L. Lalages* Heer, and species of *Sassafras*; and, as *Ceratopetalum myricinum* of de la Harpe is probably a Myrica, this also may have been one of the wax-yielding species of the era. And although no Populus has yet been identified from the basin, species are common in the Tertiary of other parts of Europe and of America, and plants of the genus probably contributed largely towards these lignitic beds.

GILBERTITE *Thom.*, Min., 1, 236. Perhaps an impure kaolinite. Whitish and silky; H.=2·75; G.=2·65. Lehunt obtained (l. c.) $\ddot{\mathrm{Si}}$ 45·15, $\bar{\ddot{\mathrm{Al}}}$ 40·11, $\dot{\mathrm{Fe}}$ 2·43, $\dot{\mathrm{Mg}}$ 1·90, $\dot{\mathrm{Ca}}$ 4·17, $\dot{\mathrm{H}}$ 4·25. From the lode of Stonagwyn, near St. Austle, Cornwall.

GISMONDITE (372, p. 418). Vom Rath mentions Frauenberg, near Fulda, as a new locality of this rare mineral. He speaks of the form as a tetragonal octahedron, and obtained for the angle between two planes over a basal angle 61° 3¼′, 61° 4′, which gives for the terminal edge 118° 56¼′, 118° 56′. The crystals are in druses in basalt with phillipsite.

GLAUCODOT (95, p. 80). Occurs, according to Tschermak (Ber. Ak. Wien, xv. 1867) and v Kobell (J. pr. Ch., cii. 409), at Hakansbö in Sweden. The crystals have the new plane 2-ĭ Basal cleavage less perfect than in the Chilian variety. G.=5·973, Tsch.; 5·96, v. K. Analyses

	As	S	Co	Ni	Fe	$\ddot{\mathrm{Si}}$
1.	44·03	19·80	16·06		19·34	——=99·23 E. Ludwig.
2.	44·30	19·85	15·00	0·80	19·07	0·98=100 v. Kobell.

GOLD (1, p. 8). Gold occurs in copper pyrites in the region of Black Bay, on the north shore of Lake Superior, between Neepigon and Thunder Bay, as observed by Chapman, and silver in the galenite of the same veins. The rocks, Chapman remarks, are not Laurentian or Azoic, although metamorphic, but altered Silurian, or "identical in general age with the gold-bearing rocks of eastern Canada and Nova Scotia."

D. Forbes has published analyses of Welsh gold Phil. Mag., IV. xxxiv. 340):

	Au	Ag	Fe	Quartz
1. Clogau	90·16	9·26	*tr.*	0·32, Cu *tr.*=99·74.
2. "	89·83	9·24	*tr.*	0·74=99·81.
3. Mawddach R.	84·89	13·99	0·34	0·43, Cu *tr.*=99·65.

Nos. 1 and 2 were from a quartz vein, associated with tetradymite, pyrite, chalcopyrite, galenite, chlorite, calcite, dolomite, ankerite? siderite, and barita. G. of 1=17·26. No. 3 was stream gold associated with menaccanite. G.=15·79.

Gold from the Stanislaus mine, Cal., gave Genth Au 88·63, Ag 11·37 (Am. J. Sci., II. xlv. 31).

HARMOTOME (390, p. 439). Descloizeaux has subjected crystals of the morvenite variety to a new examination (L'Institut, 1868, 35), and finds that they are optically *monoclinic* instead of orthorhombic; and observes, consequently, that they are not hemihedral as suggested by Gadolin, and as stated on p. 440.

HEMATITE (180, p. 140). New forms of crystals of hematite from Keswick, Cumberland, and from Elba, have been described by Hessenberg (Min. Not., No. 8), adding the new planes $\frac{1}{9}$, $-\frac{5}{26}$, from the former, and $\frac{1}{10}$ and $-\frac{4}{7}$ from the latter.

HESSITE (58, p. 50). Analyses of hessite from the Stanislaus mine by F. A. Genth (Am. J. Sci., II. xlv. 311, 1868):

	Te	Au	Ag	Pb	Ni
1.	44·45	3·28	46·34	1·65	4·71=100·43.
2.	[39·64]	3·22	55·60	—	1·54=100.

In No. 1, 7·21 p. c. of impurity are excluded, of which 4·22 was free gold and the balance quartz; and in No. 2, 28·60 p. c., including 6 p. c. free gold. Genth concludes that the mineral is a mixture of hessite with altaite and his new species melonite ($Ni_2 Te_3$); anal. 1 giving 78·11 hessite, 2·67 altaite, and 20·03 melonite, while 2 has 92·82 hessite and 6·55 melonite.

HYDROBUCHOLZITE of Thomson. Thomson obtained (Min., i. 237) $\ddot{\mathrm{Si}}$ 41·35, $\bar{\dddot{\mathrm{Al}}}$ 49·55, $\dot{\mathrm{H}}$ 4·85, gypsum 3·12=98·87. Probably from Sardinia.

HUYSSENITE. Eisenstassfurtit *Huyssen*, Berggeist, x. 67, 1865, Jahrb. Min. 1865, 329: Stassfurtit *Bischof*, ib.; Huyssenite *Dana*. (597 A.) This borate, briefly alluded to on page 596, appears to be a distinct species, and has the following characters:

Massive, and in nodular concretionary forms. G.=2·78; but after removal of mixed chlorids, 3·09. Lustre feeble. Color greenish-gray, becoming yellow on exposure, from the iron present.

Composition according to Bischof: $\dot{\mathrm{Mg}}^3 \dddot{\mathrm{B}}^4$ 40·36, $\dot{\mathrm{Fe}}^3 \dddot{\mathrm{B}}^4$ 50·05, Mg Cl 9·59=100, corresponding to the formula $(\frac{1}{2}\dot{\mathrm{Mg}}+\frac{1}{2}\dot{\mathrm{Fe}})^3 \dddot{\mathrm{B}}^4$.

Occurs at the salt mine of Stassfurt, with stassfurtite, which it much resembles; its nodules contain usually a nucleus of common salt, while those of stassfurtite have one of red carnallite.

HYALOPHANE (313, p. 346). An analysis of this mineral from Binnenthal gave T. Petersen (Jahresb. 1866, 928) $\ddot{\mathrm{Si}}$ 51·84, $\bar{\dddot{\mathrm{Al}}}$ 22·08, $\dot{\mathrm{Mg}}$ 0·10, $\dot{\mathrm{Ca}}$ 0·65, $\dot{\mathrm{Ba}}$ 14·82, $\dot{\mathrm{K}}$, $\dot{\mathrm{Na}}$ [10·03], $\dot{\mathrm{H}}$ 0·48=100.

HYDROSILICITE *v. Walt.*, Vulk. Gest., 305. (349 A.) An amorphous substance or crust from Palagonia and Aci Castello, Sicily, which afforded v. Waltershausen $\ddot{\mathrm{Si}}$ 44·90, $\dot{\mathrm{Mg}}$ 4·60, $\dot{\mathrm{Ca}}$ 33·32, $\dot{\mathrm{Na}}$ 2·11, $\dot{\mathrm{K}}$ 1·86, $\dot{\mathrm{H}}$ 13·21=100; and another variety, $\ddot{\mathrm{Si}}$ 43·31, $\bar{\dddot{\mathrm{Al}}}$ 3·14, $\dot{\mathrm{Mg}}$ 8·66, $\dot{\mathrm{Ca}}$ 28·70, $\dot{\mathrm{Na}}\,\dot{\mathrm{K}}$ 1·70, $\dot{\mathrm{H}}$ 14·48=100. Corresponds nearly to the formula $\dot{\mathrm{R}}\,\ddot{\mathrm{Si}}+\dot{\mathrm{H}}$.

HYDROTALCITE (214, p. 179). E. W. Root has obtained (priv. contrib.) for houghite from Somerville, N. Y.:

	$\bar{\dddot{\mathrm{Al}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{C}}$	Insol.
1.	21·90	31·07	30·65	6·91	8·89=99·42.
2.	21·61	31·52	30·55	6·88	9·15=99·71.
Mean	21·75	31·24	30·60	6·89	9·02=99·50.

The insoluble in No. 2 consisted of 4·43 $\ddot{\mathrm{Si}}$ and 4·36 undecomposed mica, etc. The results accord closely with those of Johnson.

HYPOXANTHITE *Rowney*, Ed. N. Phil. J., II. ii. 308, 1855; Sienna Earth. A brownish yellow ferruginous clay or ochre, probably only clayey yellow ochre. G.=3·46. Analysis obtained $\ddot{\mathrm{Si}}$ 11·14, $\dddot{\bar{\mathrm{Al}}}$ 9·47, $\dddot{\bar{\mathrm{Fe}}}$ 65·35, $\dot{\mathrm{Ca}}$ 0·53, $\dot{\mathrm{Mg}}$ 0·03, $\dot{\mathrm{H}}$ 18·00=99·52.

JAMESONITE (112, p. 90). Jamesonite from Eusebi vein, Przibram, Bohemia (v. Zepharovich, Ber. Ak. Wien, lvi. June, 1867), afforded R. Helmhacker S 20·21, Sb 30·81, As *tr.*, Pb 47·15, Fe 1·35=99·54.

Occurs in fine fibrous plates and lenticular masses in granular galenite.

809. **JAULINGITE.** Pt. of Jaulingite *v. Zepharovich*, Ber. Ak. Wien, xvi. 366, 1855. Amorphous, resin-like. Brownish-yellow. Brittle. At 50°C. softens, 70°C. liquid. Easily soluble in alcohol and ether. Aromatic odor when heated. Ratio for $\bar{\mathrm{C}}$, H, $\bar{\mathrm{O}}$=39 : 60 : 4½=$\bar{\mathrm{C}}_{26}\mathrm{H}_{40}\bar{\mathrm{O}}_{3}$, Ragsky, who obtained (½) C 77·97, H 10·14, O 11·89=100. Not soluble in a carbonated alkali, and scarcely at all in a potash solution. The above was dissolved out of a resin (called Jauliugite by v. Z., because occurring at the Jauling, near St. Viet, in Lower Austria) by means of sulphid of carbon. The resin somewhat resembles amber, is hyacinth-red, translucent in thin splinters, may be rubbed to a yellow powder between the fingers, and has H.=2·5, G.=1·098—1·111.

813A. A *Beta-jaulingite* was obtained from the residue, after the treatment with sulphid of carbon, by the action of ether. Color brownish-yellow. Softens at 135° C., and becomes liquid at 160°. Dissolves easily in alcohol and ether, but not in carbonated alkali or sulphid of carbon. Ratio for $\bar{\mathrm{C}}$, H, $\bar{\mathrm{O}}$=40 : 53⅓ : 8⅞; or 18 : 24 : 4, Ragsky, who obtained (½) C 70·90, H 7·93, O 21·17 =100. It contains double the oxygen of the preceding, with less, proportionally, of hydrogen. The ratio is nearest to that of guyaquillite (No. 813).

KIRWANITE *Thom.*, Min., i. 378, 1836. A fibrous, green, chlorite-like mineral from the basalt of the N.E. coast of Ireland. R. D. Thomson found in it (l. c.) $\ddot{\mathrm{Si}}$ 40·5, $\dddot{\bar{\mathrm{Al}}}$ 11·41, $\dot{\mathrm{Fe}}$ 23·91, $\dot{\mathrm{Ca}}$ 19·78, $\dot{\mathrm{H}}$ 4·35=99·95.

LEEDSITE *Thom.* A mixture of $\dot{\mathrm{Ca}}\dddot{\mathrm{S}}$ 71·9, $\dot{\mathrm{Ba}}\dddot{\mathrm{S}}$ 28·1, from near Leeds.

LESLEYITE *I. Lea*, Proc. Ac. Philad., 1867, 44. A soft fibrous mineral found near Unionville, Pa., on corundum, yet undescribed, and not proved to be a new species.

MAGNETITE (186, p. 140). A *niccoliferous* magnetite occurs, according to Petersen (Jahrb. Min. 1867, 836), north of Pregratten in the eastern Alps. He obtained for one specimen, on analysis, $\dddot{\bar{\mathrm{Fe}}}$ 68·92, $\dot{\mathrm{Fe}}$ 29·32, $\dot{\mathrm{Ni}}$ 1·76, $\dddot{\bar{\mathrm{Mn}}}$, $\dddot{\bar{\mathrm{Cr}}}$, $\ddot{\mathrm{Ti}}$ *tr.*=100.

MARCASITE (90, p. 75). C. Mène has observed that the pyrites of unaltered sedimentary beds is mostly marcasite, while that of metamorphic rocks is pyrite (C. R., lxiv. 867). The following analyses are by him:

	G.	S	Fe	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{H}}$	Organ.
1. Champagne	4·1759	(½) 46·4	40·9	8·4	1·7	2·1	—=99·5.
2. Ain	4·1822	(½) 48·2	42·0	5·8	1·4	1·4	0·3, $\dot{\mathrm{Ca}}$ 0·7=99·8.
3. Bauregard, etc.	4·2066	(½) 50·7	44·0	3·2	0·6	0·9	0·1, $\dot{\mathrm{Ca}}$ 0·2=99·7.
4. Creusot	4·1809	(½) 49·1	32·5	5·9	0·9	0·9	0·3=99·6.
5. St. Etienne	4·1803	(½) 48·5	42·3	6·6	1·0	0·7	0·3=99·4.
6. Oise and Aisne	4·1770	(½) 44·9	38·9	11·3	2·4	1·7	0·3=99·5.

Anal. 1 of nodules; 2, from the oolite ore beds of Villebois and Serrières; 3, from ammonites, from Bauregard, Mazenay, and Laverpillière; 4, 5, from the coal-beds; 6, bituminous pyrites.

MELANTERITE (664, p. 646). An impure sulphate of iron, apparently a mixture of melanterite and a sulphate of the sesquioxyd (as remarked by Kenngott, Ueb. 1865), from Bourboule, in the Dept. of Puy de Dome, France, has been named *Bourboulite* by Lefort (C. R., 1862, lv. 949, Jahrb. Min. 1863, 588). Derived apparently from the alteration of marcasite. Lefort's analyses obtained:

$\dddot{\mathrm{S}}$	$\dddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{H}}$
38·04	5·08	16·08	40·80=100.
37·55	8·71	13·83	39·91=100.
35·22	8·25	12·99	43·54=100.

It is a friable greenish substance, partly soluble in water and partly in acids.

MELONITE *F. A. Genth*, Am. J. Sci., II. xlv. 313, 1868. (100A, Appendix to Sulphids, etc.) A new tellurium mineral from among the ores of the Stanislaus mine. Form hexagonal, with eminent basal cleavage. Generally in indistinct granular and foliated particles. Lustre metallic; color reddish-white, rarely tarnished brown; streak dark gray.

Composition $\mathrm{Ni_2\,Te_3}$=Te 76·49, Ni 23·51=100. An analysis afforded Te 73·43, Ag 4·08, Pb 0·72, Ni 20·98=99·21; the nickel contained a minute trace of cobalt. B.B. in the open tube gives a sublimate fusing to colorless drops, leaving a gray mass; on charcoal burns with a bluish flame, giving a white volatile coating, and a greenish-gray residue; in R.F. with soda a gray powder of magnetic metallic nickel. Soluble in nitric acid, giving a green color, and on evaporation yielding a white crystalline powder of tellurous acid.

Genth considers the analysis to correspond to 6·60 p. c. hessite, 1·17 altaite, 2·29 native tellurium, and 89·25 melonite, which he assumes to have the composition $\mathrm{Ni_2\,Te_3}$, although he observes that the hexagonal form would better agree with the formula Ni Te. But the latter view would require that over one-third of the mixture should be native tellurium, which he thinks scarcely probable, as the material for analysis, when examined by a strong magnifier, showed a small quantity of dark colored hessite, but every other particle had a reddish hue, without the slightest admixture apparently of any grayish-white mineral.

MENACCANITE (181, p. 143). A variety of this species, from the basalt of Turner's Hill quarry, Staffordshire, gave D. Forbes (Phil. Mag., IV. xxxiv. 347), after excluding silicates and insoluble, $\ddot{\mathrm{Ti}}$ 34·28, $\bar{\mathrm{Fe}}$ 65·72; G.=4·69.

MICA GROUP. A micaceous mineral has been named *Helvetan* by R. T. Simmler (his Petrãa, 9, Keung. Ueb. 1865, 135, 1868), but without a determination of its composition or exact relations to other species. It forms part of a schist and quartzite in the gneiss formation (Alpinyte) of the Alps. H.=3—3·5; G.=2·77—3·03; lustre pearly or waxy; color gray to whitish, reddish, greenish, violet, and copper-red; streak grayish-white to reddish. In the closed tube yields little or no water. B.B. fuses with difficulty on the edges; the borax pearl is colorless when cold. Not attacked by hot acids. Stated to consist probably of silica, alumina, lime, magnesia, and protoxyd of iron.

A micaceous mineral from Chester Co., Pa., has been named *Pattersonite* by I. Lea (Proc. Ac Philad., 1867, 45), but without the mention of its distinctive characters.

MONTANITE (711, p. 668). Dr. Genth has detected this tellurate with the tetradymite of Davidson Co. N. C. (Am. J. Sci., II. xlv. 319), two analyses affording:

	$\dddot{\mathrm{Te}}$	$\bar{\mathrm{Bi}}$	$\dot{\mathrm{H}}$	$\dot{\mathrm{Cu}}$	$\bar{\mathrm{Fe}}$
1.	25·45	68·78	[3·47]	1·04	1·26=100.
2.	23·90	71·90	[2·80]	1·08	0·32=100.

Genth remarks that it is still doubtful whether the mineral contains 1 or 2 atoms of water.

MUSCOVITE (294, p. 309). New analyses of this species, with an extended discussion of the chemical composition of the different kinds of mica, have been published by Rammelsberg in ZS. G., xix. 400:

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	F	$\dot{\mathrm{H}}$
1. Uton, Sweden	45·75	35·48	1·86	—	0·52	0·42	1·58	10·36	1·32	2·50=99·79.
2. Easton, Pa.	46·74	35·10	4·00	1·53	—	0·80	—	9·63	1·05	3·36=102·21.
3. Goshen, Mass.	47·02	36·83	0·51	—	1·05	0·26	0·30[a]	9·80	0·52	3·90=100·19.
4. Aschaffenburg	47·69	33·07	3·07	2·02	—	1·78[b]	—	9·70	0·19	3·66=101·13.
5. Bengal	47·39	35·56	2·79	—	0·53[c]	0·96	0·88	9·53	0·46	4·11=102·16.

[a] With lithia. [b] With manganese. [c] With lime.

No. 1, G.=2·836, optic-axial angle 72°—73°, Senarmont; 2, G.=2·904, optic-axial angle 64·8° Quincke; 3, G.=2·859, optic-axial angle 75°—76°, Descl.; 4, G.=2·911, optic-axial angle 67·9°, Quincke; Bengal, G.=2·827, optic-axial angle 66·1°.

The mineral from Easton is evidently not the silvery mica referred on p. 307 to biotite, the optical angle of which, according to both Grailich and Blake, is less than 2°.

Mica from Royalston, Mass., afforded T. Petersen (Jahresb. 1866, 928, 1868) $\ddot{\mathrm{Si}}$ 46·03, $\bar{\mathrm{Al}}$ 32·10, $\bar{\mathrm{Fe}}$ 6·85, $\bar{\mathrm{Mn}}$ 2·48, $\dot{\mathrm{Mg}}$ 0·23, $\dot{\mathrm{Ca}}$ 0·90, $\dot{\mathrm{K}}$ 11·20=99·79; G.=2·947.

NEPHRITE. Kastner has analyzed an aluminous jade or nephrite from China (Gehlen's J. f.

459), differing from those of pp. 237, 290, 292; and Melchior and Meyer (Ber. Ak. Wien, xlix 475) a kind from New Zealand. Both are infusible, or nearly so. They obtained:

	$\ddot{\text{Si}}$	$\bar{\dddot{\text{Al}}}$	$\bar{\dddot{\text{Fe}}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
1. China	50·50	10·00	5·50	31·00	——	——	2·75, $\bar{\dddot{\text{Cr}}}$ 0·05 Kastner.
2. N. Zealand	53·01	10·83	7·18	14·50	12·40	0·97	1·11=100·00 M. & M.
3. "	55·01	13·66	3·52	21·62	——	1·42	5·04=100·27 M. & M.

For 2. O. ratio for $\dot{\text{R}}$, $\bar{\dddot{\text{R}}}$, $\ddot{\text{Si}}$, 9·5 : 7·2 . 27·5; for 3, 8·9 : 7·4 : 28·6. Nos. 2 and 3, as described by Hochstetter (l. c.), are somewhat slaty, and are hardest on the transverse surfaces of fracture. In No. 2, H.=5–5·5; in another, 3·5–5. G.=2·61. It is called *tangiwai* by the New Zealanders. B.B. thinnest splinters infusible, but becomes white and opaque. In No. 3, H.=5·5–6·5; on a polished cross face, 7. G.=3·02. B.B. fuses with great difficulty, becomes discolored and opaque. This variety contains much water.

These minerals are probably mere mixtures, as may well be true of such massive substances. For non-aluminous jade or nephrite, see p. 237.

ORTHOCLASE (316, p. 352). The twin crystals of orthoclase from Carlsbad, Bohemia, afforded Rammelsberg and Bulk (ZS. G., xviii. 393):

		$\ddot{\text{Si}}$	$\bar{\dddot{\text{Al}}}$	$\bar{\dddot{\text{Fe}}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Ba}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$
1. *White*	G.=2·573	63·02	18·28	——	0·14	——	0·48	2·41	15·67=100 Ramm.
2. *Reddish*	G.=2·55	65·23	18·26	0·27	——	*tr.*	——	1·45	14·66=99·87 C. Bulk.

White feldspar from Royalston, Mass., gave T. Petersen (Jahresb. 1866, 927, 1868) $\ddot{\text{Si}}$ 65·79, $\bar{\dddot{\text{Al}}}$ 17·46, $\bar{\dddot{\text{Fe}}}$ *tr.*, $\dot{\text{Mg}}$ *tr.*, $\dot{\text{Ca}}$ 0·59, $\dot{\text{Na}}$ 5·21, $\dot{\text{K}}$ 14·26, $\dot{\text{H}}$ 0·37=100·98. G.=2·631.

PALAGONITE (425, p. 483). Von Wartha found in the palagonite of the basaltic tufa of Battina, in Baranyer Comitat (Hungary) (Verh. G. Reichs. 1867, 210), $\ddot{\text{Si}}$ 26·99, $\bar{\dddot{\text{Al}}}$ 11·09, $\bar{\dddot{\text{Fe}}}$ 8·45, $\dot{\text{Ca}}$ 12·69, $\dot{\text{Mg}}$ 2·29, $\dot{\text{Sr}}$ 1·03, $\dot{\text{Na}}$ 0·63, $\dot{\text{K}}$ 1·07, $\dot{\text{H}}$ 11·09, $\ddot{\text{C}}$ 7·70, phosphate of lime 0·97, insoluble residue 16·81=99·89. Excluding the residue, phosphate of lime and carbonic acid, with its equivalent of lime, the results become $\ddot{\text{Si}}$ 41·78, $\bar{\dddot{\text{Al}}}$ 17·17, $\bar{\dddot{\text{Fe}}}$ 13·05, $\dot{\text{Ca}}$ 4·47, $\dot{\text{Mg}}$ 3·55, $\dot{\text{Sr}}$ 0·19, $\dot{\text{K}}$ 1·66, $\dot{\text{Na}}$ 0·97, $\dot{\text{H}}$ 17·16=100·00, corresponding very well with the composition of palagonite from other localities.

PLAGIOCLASE. Breithaupt's name for the group of triclinic feldspars, the two prominent cleavage directions in which are oblique to one another, πλάγιος signifying *oblique*.

PLOMBIERITE *Daubrée*, C. R., xlvi. 1088, 1858, Ann. d. M., V. xiii. 244. (340A.) A gelatinous substance which hardens in the open air, formed from the thermal waters of Plombières. It becomes, on hardening, opaque snow-white. It afforded, after drying at 100°C., $\ddot{\text{Si}}$ 40·6, $\bar{\dddot{\text{Al}}}$ 1·3, $\dot{\text{Ca}}$ 34·1, $\dot{\text{H}}$ 23·2=99·2, corresponding to $\dot{\text{Ca}}\,\ddot{\text{Si}}+2\,\dot{\text{H}}$, a hydrated silicate of lime.

Chabazite and apophyllite in fine crystals are other results of the action of the waters of Plombières on the brick and mortar of an old Roman aqueduct, besides hyalite, aragonite, and perhaps scolecite and harmotome.

PYRITE (75, p. 62). The pyrite associated with the niccoliferous pyrrhotite of Inverary, Scotland, gave D. Forbes (Phil. Mag., IV. xxxv. 178) S 49·32, Fe 45·73, Ni 1·99, Co 1·24, Cu 1·18, insoluble 0·06=99·52; G.=4·93. Forbes says that, in the examination of several hundred specimens of pyrite and pyrrhotite from different localities, nickel is rarely found in pyrite, while often present in pyrrhotite; on the contrary, cobalt is rather common in pyrite, and, compared with nickel, in quite small quantity in pyrrhotite.

Analyses of pyrite from different French localities by C. Mène (C. R., lxiv. 870):

	G.	S	Fe	$\ddot{\text{Si}}$	$\bar{\dddot{\text{Al}}}$	$\dot{\text{H}}$
1. Chessy and St. Bel	4·6205	$(\frac{1}{4})$ 46·5	39·3	10·0	3·8	0·2=99·8.
2. Lavoulte	4·7712	$(\frac{1}{4})$ 48·7	42·9	7·0	0·8	0·1, $\dot{\text{Ca}}$ 0·3=99·8.
3 Allevard	4·7500	48·5	42·1	6·5	2·0	0·4=99·5.
4 Aude	4·7428	49·1	43·5	6·0	1·0	0·2=99·8.
5. Elba	4·8008	52·2	43·5	4·0	0·1	——=99·8.
6. Conflens	4·8102	52·4	43·1	3·5	0·7	0·2=99·9.
7. Allier	4·8033	52·7	44·2	2·5	——	0·2=99·6.
8. Gard	4·7318	$(\frac{1}{2})$ 48·5	40·5	8·7	1·7	0·3=99·7.

Mène observes that the pyrites of unaltered sedimentary rocks is mostly *marcasite*.

PYROMELANE *C. U. Shepard*, Am. J. Sci., II. xxii. 96, 1856, Min., 253, 1857. In angular grains from the gold-washings of McDowell Co., N. C. H.=6·5; G.=3·87; lustre resinous; color reddish to yellowish-brown and black; subtranslucent. B.B. infusible, but becomes black and opaque (whence the name); soluble in the fluxes, giving reactions of titanic acid and iron. Stated to be "essentially a titanate of alumina and iron with traces of lime and glucina," and "may contain zirconia also": but the evidence of such a composition is not given. Perhaps a variety of titanite.

PYROXENE (238, p. 212). An analysis of malacolite from Gefrees (Fichtelgebirge) afforded K. Haushofer (J. pr. Ch., cii. 35) $\ddot{Si}$ 54·00, $\dddot{\bar{Al}}$ 0·62, $\dot{Fe}$ 3·78, $\dot{Mn}$ 0·27, $\dot{Mg}$ 15·31, $\dot{Ca}$ 25·46=99·65. G.=3·285.

For an article on the constitution of aluminous pyroxene and amphibole, by Rammelsberg, see ZS. G. Ges., xix. 496; and a word on the formula, by the author, p. 794.

Canaanite is a whitish *pyroxene rock*, as stated on page 322. It was called scapolite rock by Hitchcock (G. Rep. Mass., 315, 1835, 369, 1841), and later named *Canaanite* in Alger's Min., 1844, after an analysis (see below) by S. L. Dana. It is a whitish and grayish-white rock, subcrystalline in fracture, with H.=5·5 and G.=3·07, and constitutes ridges in the vicinity of Canaan, Ct. It is overlaid by a dolomite, abounding in some layers in crystals of whitish pyroxene, and at the junction is much mixed with the dolomite. Dr. Dana obtained in his analysis (Hitchcock's Rep., 569, 1841):

$\ddot{Si}$ 53·37 $\dddot{\bar{Al}}$ 10·38 $\dot{Fe}$ 4·50 $\dot{Mg}$ 1·62 $\dot{Ca}$ 25·80 $\ddot{U}$ 4·00=99·67.

A specimen has been recently analyzed by B. S. Burton (priv. contrib.), with the following results, showing that the alumina of the preceding was an error:

$\ddot{Si}$ 51·30 $\dot{Fe}$ 1·60 $\dot{Mg}$ 16·47 $\dot{Ca}$ 25·21 $\ddot{C}$ 5·91 $\dot{H}$ 0·39=100·88.

The 5·91 carbonic acid corresponds to 13·41 of carbonate of lime present as impurity. Whether the carbonate is a result of alteration or not is yet unascertained.

PYRRHOTITE (68, p. 58). Analyses of niccoliferous pyrrhotite from Inverary and from the Craigmuir mine, Scotland, by D. Forbes (Phil. Mag., IV. xxxv. 174):

	S	Fe	Ni	Co	Cu	Insol.
1. Inverary	37·50	49·97	11·17	*tr.*	*tr.*	0·24, Mg 0·96=99·84.
2. Craigmuir	37·99	50·87	10·01	1·02	*tr.*	0·38, As 0·04=100·31.

G. of 1=4·50; 2=4·602. Forbes suggests that there may be two definite compounds under niccoliferous pyrrhotite; one with the formula $5\,(Fe^7 S^8) + Ni\,S$, with 10·93 of nickel, and one $15\,(Fe^7 S^8) + Ni\,S$ with 4·10 nickel, corresponding, according to him, with many analyses of pyrrhotite from a wide range of localities.

QUARTZ (231, p. 189). See **TRIDYMITE** and **VESTAN** beyond.

REFDANSKITE *Hermann*, J. pr. Ch., cii. 405. (412A.) An earthy mineral occurring in masses which fall to powder under slight pressure. Adheres to the tongue. Color dirty grayish-green. G.=2·77. Analysis:

$\ddot{Si}$ 32·10 $\dddot{\bar{Al}}$ 3·25   Fe 12·15 $\dot{Ni}$ 18·33 $\dot{Mg}$ 11·50 $\dot{H}$ 9·50 $\dot{Mn}$, $\dot{Bi}$ *tr.*   Sand 13·00=99·83.

Or, excluding the sand, $\ddot{Si}$ 36·92, $\dddot{\bar{Al}}$ 3·73, $\dot{Fe}$ 13·97, $\dot{Ni}$ 21·07, $\dot{Mg}$ 13·22, $\dot{H}$ 10·92=99·83. O. ratio for $\dot{R}$, $\ddot{Si}$, $\dot{H}$, 3 : 4 : 2, the same as in serpentine, of which this species may be considered a niccoliferous variety (see p. 464).

RICHMONDITE. **HYPOTHETICAL PHOSPHATE.** The substance labelled gibbsite from Richmond, Mass., in which Hermann states he found 37 p. c. of phosphoric acid (see his analysis under Gibbsite, p. 178) has been named *Richmondite* by Kenngott (Vierteljahrschr. nat. Ges. Zurich, xi. 225).

SCHEELITE (614, p. 605). Rammelsberg has measured crystals from the Riesengebirge (ZS. G., xix. 493), and deduced the same dimensions as those of Dauber given on p. 605 (Pogg., cvii. 272). The crystals are unusually fine, some of them being an inch in length. They are found at Kies berg between Gross-Aupa and the Riesenbaude, as described by Roemer (ZS. G., xv. 607), who also gives some measurements of the crystals, besides a particular account of the geological character of the region.

SELBITE. Luftsaures Silber (from anal. by Selb) *Widenmann*, Min., 689, 1794, *Lenz*, Min., 95, 1794 Grausilber; Carbonate of Silver; *Selb*, Tasch. Min., xi. 394, 1817; Selbit *Haid.*, Handb., 506, 1845 A grayish ore, made a carbonate by Selb, its discoverer, in 1788, at the mine Wenzel near Wolfach, with the composition (Widenmann, l. c., here cited from Lenz, l. c.), Carbonic acid 12, oxyd of silver 72·5, antimony 15·2, with carbonic acid and oxyd of copper. According to Walchner (Mag. f. Pharm., xxv. 1) it is only a mixture; and, according to Sandberger (Jahrb. Min. 1864, 221), one of Selb's original specimens, under the lens, proved to contain within earthy argentite, besides dolomite and silver, and all parts afforded a sulphur reaction.

Del Rio described a carbonate of silver from Real Catorce, Mexico, where it is called *Plata Azul* (Gilb. Ann., lxxi. 11), which also is regarded as a mixture.

SERPENTINE (411, p. 464). An analysis of the dark green noble serpentine of Newburyport, Mass., gave T. Petersen (Jahresb. 1866, 931, 1868) $\ddot{\mathrm{Si}}$ 41·76, $\bar{\bar{\mathrm{Al}}}$ *tr.*, $\dot{\mathrm{Fe}}$ 4·06, $\dot{\mathrm{Mg}}$ 41·40, $\dot{\mathrm{H}}$ 13·40 =100·62. G.=2·804.

SILICATE OF YTTRIA *Damour*, L'Institut, 1853, 78. H.=5–6; scratches glass. G.=4·391. Color brown. Probably a silicate of yttria. B.B. whitens, but infusible. Not soluble in salt of phosphorus. Sulphuric acid heated to 300°C. decomposes it, leaving a siliceous residue.

From the diamond sands of Bahia, Brazil.

TENORITE (Melaconite, 178, p. 136). The *tenorite*, or oxyd of copper (Cu O) in small delicate folia, occurring at Vesuvius, possesses, according to Maskelyne (Rep. Brit. Assoc., 1865, 33), double refraction, and moreover is optically biaxial. This author also states that there are two equal cleavages inclined to one another 72°. As the names tenorite and melaconite were given the same year, and tenorite was made non-isometric (hexagonal) by its describer, it appears to be right that tenorite should be sustained for the above mineral, and melaconite be left for the isometric kind, if any such proves to be a native species. That there is an isometric form of this Cu O has been announced by Becquerel, as stated on p. 137. Tenorite may have the form and dimensions found by Jenzsch in crystals of Cu O from the hearth of a furnace (l. c.), or those approximately of brookite; and this would place it near *brookite* in the system, under the chemical formula $\mathrm{\bar{C}u\,O_2}$ (analogous to that of brookite). Having this place in the arrangement it would be numbered 198B.

Melaconite crystals from Cornwall, collected by Mr. Talling, have been described by Maskelyne (l. c.) as *monoclinic*, with the planes *O*, *i-i*, *I*, 1, –1, 6-*i*, 6-*ĭ*, and *O* ∧ *i-i*=80° 28′. No measured angles are given, but only the deduced dimensions. They have basal cleavage easy. The crystals are often twins, and the composition-face in some of them is *i-i*. H. a little above 4; G.=5·82527. Church has ascertained that the crystals are essentially pure Cu O.

It would appear, according to these observations, that this oxyd of copper is trimorphous; and there exists a doubt whether tenorite may not have this oblique form.

TETRADYMITE (31, p. 30). F. A. Genth has analyzed tetradymite from Highland, Montana Territory, and from the Phœnix mine, Cabarras Co., N. C., as follows (Am. J. Sci., II. xlv. 317):

	Te	Bi	S	Fe	Cu	Quartz.
1. Montana	47·60	50·43	——	0·90	——	0·78=100·01.
2. Phœnix mine	36·28	57·70	5·01	Fe 0·54	0·41	——=~~99·04.~~

No. 1 gives the ratio of Bi and Te 2 : 3, like the tetradymite from Fluvanna Co., Va., and Field's mine, Ga. No. 2 contains a small amount of pyrite, leaving 4·40 p. c. sulphur combined with the bismuth, and giving the ratio of S, Te, Bi=1 : 2·03 : 2=$\mathrm{Bi^2\,S^3+2\,Bi^2\,Te^3}$.

TETRAHEDRITE (125, p. 100). The following are new analyses:

1. Mineral from the Goodwin mine near Prescott, Arizona, by F. A. Genth (Am. J. Sci., II. xlv 320).

2. An argentiferous variety (freibergite) from the Foxdale mine, Isle of Man, by D. Forbes (Phil. Mag., IV. xxxiv. 350), who calls it *polytelite*, though not the true polytelite of Glocker (p. 104), by whom this name was introduced; G.=4·97. Forbes mentions a similar variety from the Tyddynglwadis mine in N. Wales.

3. Freibergite from the De Soto mine, Star City, Nevada, by B. S. Burton (Am. J. Sci., II. xlv 320): G.=5.

	S	Sb	As	Cu	Fe	Zn	Ag	Pb
1. Arizona	26·97	24·67	*tr.*	38·16	1·05	6·28	3·21	——=100·29 Genth.
2. Isle of Man	27·48	24·85	—	22·62	4·80	4·65	13·57	1·43, quartz 0·34=99·74 Forbe
3. Nevada	24·35	27·35	—	27·40	4·27	2·31	14 59	——, insol. 0·35=100 62 Burt

From No. 1, 4·22 p. c. of quartz have been deducted.

TIEMANNITE (65, p. 56). Analysis of this species from Charlotte mine, at Clausthal in the Harz, gave T. Petersen (Jahresb. 1866, 919), after excluding oxyd of iron and gangue, Se 24·85, S 0·20, Hg 75·15, Pb 0·12=100·35. G.=7·15.

TITANITE (329, p. 383). Hessenberg, in No. 8 of his Min. Not. (1868), describes and figures crystals of sphene from Zillerthal, Greiseralp, St. Marcel (greenovite), Santorin.

In the lettering on the figures, pp. 383, 384, and in the accompanying text, the *minus* symbols should properly (according to the principle on p. xxvii) be *plus*, and the reverse.

TRICHITE, BELONITE. The name *Trichite* (from θρίξ, *hair*) is applied by Zirkel (ZS. G., xix. 744, 1867) to microscopic *capillary* forms, often curved, bent, or zigzag, sometimes stellately aggregated, opaque and black or reddish-brown, of undetermined nature, which he detected in some kinds of glassy or semi-glassy volcanic rocks; and *Belonite* (ib., 738) to microscopic *acicular* crystals (whence the name, from βελόνη, *a needle*), colorless and transparent. The trichite, he states, is not pyroxene or hornblende; the belonite may be a feldspar.

TRIDYMITE *Vom Rath*, Vorgetr. Ch. Ges. Bonn, March 7, 1866, pub. in 1868 (copy rec'd from v. R., May 8, 1868). (231A.) Besides the two well-known forms of silica, quartz and opal, and the two problematical forms described by Jenzsch (pp. 201, and below), another is announced by v Rath under the above name.

Tridymite occurs in small hexagonal tables, colorless and transparent, which are usually compound, and mostly of three individuals. It has G.=2·2—2·3, or the low specific gravity of opal, instead of that of ordinary quartz. Vom Rath alludes to the possibility of its being a pseudomorph of some unknown mineral, but observes that it has the double refraction of a substance optically uniaxial. It occurs in druses in a volcanic porphyry, from Cerro St Cristoval, near Pachucha, Mexico, along with crystals of hematite and needles of a gold-lustred hornblende Named in allusion to its compound forms of three individuals, or *trins*, from τρίδυμος.

URANOPHANE *Websky*, ZS. G., v. 427, 1853, xi. 384. (376B?) Orthorhombic, $I \wedge I=146°$ from $I \wedge i\text{-}\bar{i}=107°$; a macrodome of about 90°. Crystals microscopic acicular six-sided prisms in druses, containing also sometimes crystals of torbernite. Color of isolated crystals honey-yellow, of masses leek-green, sometimes blackish-green from mixture with uraninite. Optically orthorhombic. H. below 3. G.=2·6—2·8; 2·78 of a specimen not wholly pure. Lustre of face $i\text{-}\bar{i}$ pearly, elsewhere vitreous.

Analyses by Grundmann (ZS. G., xi. 390):

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dddot{\bar{\mathrm{U}}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{K}}$	$\dddot{\bar{\mathrm{P}}}$	$\dot{\mathrm{H}}$	Bi	Sb	Te	Fe	Pb	Cu	Ag	S
1.	15·81	5·65	49·84	1·35	4·69	1·71	0·12	14·11	1·73	1·46	0·43	0·57	0·29	0·21	0·11	1·66=99·74.
2.	11·19	2·80	54·23	1·19	3·58	0·80	0·05	12·19	1·77	1·86	0·22	0·89	0·38	5·24	?	3·96=100·34.

Separating the sulphids as impurities from No. 1, Websky deduces the O. ratio for $\dot{\mathrm{R}}$, $\dddot{\bar{\mathrm{R}}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}=1:5:4:6$, making it hence, if the water be taken as accessory, a ⅔-subsilicate; whence the formula $(\frac{1}{6}\dot{\mathrm{R}}^3+\frac{5}{6}\dddot{\bar{\mathrm{R}}})\ddot{\mathrm{Si}}+3\dot{\mathrm{H}}$. The specimen for the second analysis contained some uraninite. Found in granite, at Kupferberg in Silesia.

VALAITE. Válait *W. Helmhacker*, Jahrb. G. Reichs, xvii. 210, 1867. Crystallized. Partly in small hexagonal tables, but forms not distinct. Also massive. H. below 1·5. Lustre shining. Color pitch-black. Streak black. Odor aromatic when rubbed between the fingers. Fracture uneven.

Belongs among the resins, but composition undetermined. B.B. swells to more than 10 times its former bulk, and becomes a light, porous mass, which in a higher heat is reduced to a grayish ash.

Occurs in thin crusts on dolomite and calcite, or in druses of small crystals, in the Rossitz-Oslawaner Coal formation, Moravia. It is associated with hatchettite, and the same bed affords some mineral oil.

VESTAN *Jenzsch*, Pogg., cv. 320, 1858. Quartz under a triclinic form, according to Jenzsch's observations. The angles are stated to be only approximative. Two of them, 95½° and 138°, are very near $R \wedge R$ and $R \wedge -R$ in ordinary quartz; G.=2·65—2·66, as in quartz. The observations need confirmation. The crystals here referred occur mostly in melaphyre, and the localities mentioned are mainly in Saxony and the Thuringer Wald.

VOLGERITE (229, p. 188). The name *Volgerite* was given by the author (Min., 142, 1854) to Volger's mineral, for which Volger wrote the formula adopted as that of the species on p. 188 The African mineral analysed by Cumenge, which is referred on the same page to Volgerite, although of somewhat doubtful composition, is the *Cumengite* of Kenngott (Min., 29, 1853).

WASITE *J. F. Bahr*, Pogg., cxix. 572, 1863. A mineral resembling allanite, of a brownish-black color, but yellowish-brown in thin splinters and powder, with traces of cleavage in one direction. According to a qualitative examination by Bahr, it contains silica, alumina, yttria, sesquioxyd of iron, cerium, didymium, calcium, manganese, lime, alkali, a trace of uranium, without glucina, together with the oxyd of a new metal he named *wasium* (after the royal family of Wasa, Sweden). In a later paper (Ann. Ch. Pharm., cxxxii. 127), Bahr makes this oxyd thoria. Nicklès had suggested previously that it might be impure cerium.

From Rönsholm, an island near Stockholm. The relations of the mineral remain doubtful.

WERNERITE (299, p. 320). The pink scapolite of Bolton, Mass., yielded T. Petersen (Jahresb. 1866, 928, 1868) $\ddot{S}i$ 48·34, $\bar{\bar{A}}l$ 29·09, $\dot{C}a$ 15·40, $\dot{N}a$, with a little $\dot{K}$ [6·55], $\dot{H}$ 0·62=100. G.=2·719. The analysis agrees very closely with that by Wolff (p. 320).

WÖHLERITE (265, p. 261). According to new optical investigations by Descloizeaux (L'Institut, 1868, 35), wöhlerite crystals are monoclinic instead of orthorhombic.

ZOISITE (280, p. 290). Damour (C.R., lxiii. 1038) found on analysis of an ancient stone implement from Neuchatel a composition corresponding to that of *saussurite*, $\ddot{S}i$ 50·69, $\bar{\bar{A}}l$ 25·65, $\ddot{\bar{F}}e$ 2·50, $\dot{M}g$ 5·76, $\dot{C}a$ 10·61, $\dot{N}a$ 4·64, ign. 0·30=100·15. G.=3·20—3·43.

A zoisite from Pinzgau has part of the alumina replaced by oxyd of chrome, according to F. Sandberger (Jahrb. Min. 1867 884). A chrome zoisite has also been mentioned by Breithaupt as occurring in Salzburg.

APPENDIXES

TO THE

FIFTH EDITION

OF

DANA'S MINERALOGY.

APPENDIX I., 1868-1872,

BY GEORGE J. BRUSH.

APPENDIX II., 1872-1875,

AND

APPENDIX III., 1875-1882,

BY EDWARD S. DANA.

NEW YORK:
JOHN WILEY AND SONS,
53 EAST TENTH STREET,
Second door west of Broadway.
1890.

FIRST APPENDIX

TO THE

FIFTH EDITION

OF

DANA'S MINERALOGY,

BY

GEORGE J. BRUSH,

PROFESSOR OF MINERALOGY IN THE SHEFFIELD SCIENTIFIC SCHOOL OF YALE COLLEGE

COMPLETING THE WORK TO 1872.

NEW YORK:
JOHN WILEY AND SONS,
53 East Tenth Street,
Second door west of Broadway.
1890.

Entered according to Act of Congress, in the year 1872, by
JOHN WILEY & SON,
In the Office of the Librarian of Congress, at Washington.

PREFATORY NOTE.

THIS Appendix, prepared with the co-operation of Professor DANA, is intended as one of a series to be published from time to time. It includes descriptions of 87 minerals announced as new, and also some important facts regarding a few old species, published since the appearance of the Mineralogy in 1868.

An alphabetical arrangement is adopted for convenience of reference. The species included, arranged according to the general subdivisions in the classification of minerals, are as follows:—

1. *Native Elements.*

1. Diamond.
2. Maldonite.

2. *Sulphids, Arsenids, etc.*

3. Arsenical Cobalt, Einfach-Arsenik-Cobalt.
4. Beyrichite.
5. Diaphorite.
6. Dyscrasite: Stibiotriargentite, Stibiohexargentite.
7. Epiboulangerite.
8. Epigenite.
9. Glaucopyrite.
10. Julianite.
11. Klaprotholite.
12. Metacinnabarite.
13. Orileyite.
14. Osbornite.
15. Polyargyrite.
16. Rionite.
17. Tellurwismuthsilber.
18. Wolfachite.
19. Sylvanite.

3. *Chlorids, Fluorids.*

20. Nadorite, Sb, Pb, Cl, O.
21. Nantokite, Cu^2 Cl.
22. Ralstonite, Al, Fl, H.
23. Sellaite, Mg Fl.

4. *Oxyds.*

24. Chrompicotite (Spinel group).
25. Ilsemannite, $\ddot{M}o + 4\dddot{M}o$.
26. Jacobsite (Spinel group).
27. Lithiophorite (near Asbolan).
28. Namaqualite (near Hydrotalcite).
29. Rabdionite.
30. Brookite.
31. Tridymite.

5. *Anhydrous Silicates.*

32. Amblystegite (Hypersthenite).
33. Aspidolite (Mica Group).
34. Asteroite (Pyroxene).
35. Barettite.
36. Bismutoferrite.
37. Hortonolite (Chrysolite Group).
38. Monzonite.
39. Roepperite (Chrysolite Group).

6. *Hydrous Silicates.*

40. Antillite (near Serpentine).
41. Aquacreptite (near Hydrophite).
42. Cyanochalcite (near Chrysocolla).
43. Diabantachronnyn (Chlorite Group).
44. Ephesite.
45. Epiphanite (near Enkamptite).
46. Euralite (near Delessite).
47. Gümbelite (near Pinite).
48. Hallite.
49. Hypochlorite.
50. Ivigtite.
51. Milarite (a Zeolite ?).
52. Næsumite.
53. Nigrescite.
54. Plumballophane.
55. Restormelite.
56. Reissite (near Monophane).
57. Talcosite.
58. Uranotil.
59. Westanite (near Wörthite).
60. Lesleyite.
61. Pattersonite.
62. Selwynite.

7. *Tantalates, Columbates.*

63. Ferroilmenite (Columbite).
64. Kochelite (near Fergusonite).

8. *Phosphates, Arsenates, etc.*

65. Andrewsite.
66. Cœruleolactite.
67. Durangite.
68. Guano Phosphates.
69. Isoclasite.
70. Kollophan.
71. Lime-Wavellite.
72. Lünebergite.
73. Montebrasite (Amblygonite).
74. Redondite.
75. Sarcopside (Triplite).
76. Trögerite.
77. Walpurgite.
78. Zepharovichite.

9. *Borates.*

79. Sussexite.
80. Winkworthite.

10. *Tungstates, Molybdates, Vanadates.*

81. Wolframite.
82. Eosite.
83. Pucherite.
84. Vanadiolite.

11. *Sulphates, Chromates.*

85. Guano Sulphates.
86. Caledonite.
87. Simonyite.
88. Laxmannite.
89. Phosphochromite.

12. *Carbonates, Oxalates.*

90. Bastnaesite (Hamartite)
91. Guano-oxalates.

13. *Carbo-hydrogen Compounds.*

92. Ambrosine.
93. Bernardinite.
94. Trinkerite.
95. Wollongongite.

APPENDIX I.*

1. *Minerals described as new species.*

411. *Antillite.*—A name given by C. U. Shepard to a substance he considers to be a hydrated bronzite. It occurs both massive and crystalline, presenting minute coppery laminæ, with a fibrous cleavage. H.=3·5–4. G.=2·52. Color dark greenish-brown. An analysis gave $\ddot{\mathrm{Si}}$ 39·30, $\dot{\mathrm{Mg}}$ 36·12, $\dot{\mathrm{Fe}}$ 6·70, $\dot{\mathrm{H}}$ 16·79, with traces of $\dot{\mathrm{Cr}}$, $\dot{\mathrm{Ca}}$, $\dot{\mathrm{K}}$=98·91. This composition approaches that of serpentine or deweylite. (Appendix to Catalogue of Meteorites, Amherst, Mass., January 1, 1872).

235. AMBLYSTEGITE.—*G. vom Rath*, Pogg. Ann., cxxxviii. 531.

Orthorhombic: $i\text{-}\bar{i} \wedge I=135°\ 50'$, $i\text{-}\bar{i} \wedge 1\text{-}2=119°\ 26'$, $\frac{1}{4}\text{-}\breve{i} \wedge \frac{1}{4}\text{-}\bar{i}=163°\ 47'$, $i\ \breve{i} \wedge \frac{1}{4}\ \breve{i}=98°\ 6\frac{1}{2}'$. Cleavage not observed. Hardness nearly equal to quartz. G.=3·454. Lustre adamantine-vitreous. Color brown to reddish-brown. Streak greenish-gray. Translucent. Fracture conchoidal. Analysis, G. vom Rath (l. c.):

$\ddot{\mathrm{Si}}$	$\dddot{\overline{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$
49·8	5·05	25·6	17·7	0·15=98·30

Only half a gram was available for analysis, and the state of oxydation of the iron was not determined. B. B. difficultly fusible without intumescence to a black glass. Not decomposed by muriatic acid. Found at Lake Laach. Amblystegite is closely related to hypersthenite in form and chemical composition. V. v. Lang has recently discovered crystals of hypersthenite in the meteorite of Breitenbach which give the same planes as amblystegite, and vom Rath now announces (Jahrb. Min., 1871, 642) the identity of his supposed new species with hypersthenite.

799 B. AMBROSINE. *C. U. Shepard*, Rural Carolinian, i. p. 311.

In rounded masses. Color yellowish to clove-brown. Fracture conchoidal. Lustre, resinous. Becomes electric on friction. Melts at about 460°F. to a clear yellowish liquid; softens at a lower temperature. Gives off "succinic acid" before melting; on fusion gives an agreeable balsam odor, unlike that from the resins of ordinary pines, and a dark brown non-volatile fluid remains as long as the melting heat is kept up. Combustible, leaves no ash. Soluble for the most part in oil of turpentine, alcohol, ether, and chloroform, as also in potash. Found in the phosphatic beds near Charleston, S. C., having originated in the eocene formation.

ANDREWSITE. *N. S. Maskelyne*, Chem. News, xxiv. 99.

In globular disks with radiated structure resembling wavellite. G.=3·475. Color bluish-green. Composition, a hydrous phosphate of iron and copper. An average of four determinations gave 10·82 per cent. of copper; and according to Maskelyne the analyses (not given in the article quoted) "justify the formula $3\,(\dddot{\overline{\mathrm{Fe}}}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\mathrm{P}}},\ \dddot{\overline{\mathrm{Fe}}}\,\dot{\mathrm{H}}^3) + \dot{\mathrm{Cu}}^3\,\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\mathrm{P}}}$, in which, however, a portion of the ferric phosphate is replaced by ferrous phosphate, as in vivianite is frequently the case with the two phosphates."

Occurs in Cornwall on a quartzose veinstone associated with limonite and göthite, and interpenetrated with a mineral resembling, if not identical with, dufrenite. Requires further description.

71 A. *Arsenical cobalt.* Under the title *Einfach-arsenik-cobalt*, Kenngott calls attention to a mineral which appears to be hexagonally crystallized arsenid of cobalt, occurring with barite and quartz at Bieber (Jahrb. Min., 1869, 754).

---

* This appendix contains descriptions of minerals announced as new since the publication of this work in 1868. A few notes are added at the end, on previously described species. It has been prepared by Prof. G. J. Brush. The black-faced figures indicate the number of the species, as arranged in the classification adopted in the Mineralogy.—NEW HAVEN, March 1, 1872

288 A. **ASPIDOLITE.**—Aspidolith, *F. v. Kobell*, Ber. Ak. München, March 6, 1869.

Orthorhombic: in prisms giving approximatively 120° and 60°. The smaller sides show reëntering angles from twinning, or an aggregation of several crystals, giving the base an oval shield-like appearance. Optically biaxial, with the divergence angle 11° 55′ for the red rays. Bisectrix normal to cleavage plane. H.=1–2. G.=2·72. Lustre pearly, submetallic. Color olive-green, in thin leaves brownish-yellow. Foliated, leaves flexible, but not elastic. An analysis afforded von Kobell:

$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
46·44	10·50	26·30	9·00	4·77	2·52	1·33=100·86

The oxygen ratio of $\dot{\mathrm{R}}$, $\dddot{\mathrm{R}}$, and $\ddot{\mathrm{Si}}$ is 14·16 : 4·91 : 24·66, or 3 : 1 : 5. The composition approaches that of a soda phlogopite.

B. B. exfoliates like vermiculite, giving water in the closed tube. In the forceps difficultly fusible to a dirty gray-white glass. Entirely decomposed by muriatic acid, leaving the silica in pearly scales.

Found in Zillerthal, in Tyrol, associated with chlorite.

238. *Asteroite*—A name given to a variety of stellate radiated pyroxene, from Nordmark, in Sweden, by L. J. Igelström (B. and H. Ztg. xxix. 8, 1870). It is ash-gray to white in color, has a silky lustre, is opaque, becomes bronze color on exposure. Analysis gave $\ddot{\mathrm{Si}}$ 48·48, $\dot{\mathrm{Fe}}$ 22·24, $\dot{\mathrm{Mn}}$ 4·12, $\dot{\mathrm{Ca}}$ 17·00, $\dot{\mathrm{Mg}}$ 4·18, ignition 2·83=98·85. The oxygen ratio of $\dot{\mathrm{R}}$ to $\ddot{\mathrm{Si}}$ is 1:2. It is a pyroxene near hedenbergite, but containing a portion of the iron replaced by manganese.

415 B. **AQUACREPTITE.**—*C. U. Shepard*, Am. J. Sci. II. xlvii. 256.

Massive, occurring in irregular polyhedral fragments, with flat or concave surfaces. H.=2·5. G.=2·05—2·08. Lustre dull. Color yellowish-brown. Streak orange-yellow. Brittle. Adheres to the tongue. Falls to pieces in water, with a crackling noise.

Analyses—1. C. U. Shepard; 2. J. H. Eaton (l. c.):

	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{H}}$
1.	41·00	4·00	17·60	13·30	23·00=98·90
2.	43·03	5·56	19·58	12·30	17·40=97·87

Decomposed by muriatic acid. Found in a vein in serpentine, at Westchester, Pa. It is near hydrophite. Needs further investigation.

732 A. **BASTNÄSITE.** *Huot*, *Min.* i. 296 (1841). Basiskfluorcerium, *Hisinger*, Œf. Ak. Stockh., 1838, 189. Hamartite, *A. E. Nordenskiöld*, Œf. Ak. Stockh., 1868, 399.

The so-called basic fluorid of cerium, from Bastnäs, examined by Hisinger, has been reëxamined by A. E. Nordenskiöld, and shown to be a fluo-carbonate. As the name basic fluorid, or hydrofluocerite, conveys an incorrect idea of the composition of the mineral, Nordenskiöld gives it the new name *hamartite*, overlooking the fact that Huot had already named the mineral *bastnäsite*, after the locality.

Orthorhombic?—Found in small masses imbedded between allanite crystals. Shows distinct cleavage. H.=4. G.=4·93. Lustre greasy. Color wax-yellow.

Composition Ce F+2 ($\dot{\mathrm{Ce}}$, $\dot{\mathrm{La}}$) $\ddot{\mathrm{C}}$=$\dot{\mathrm{La}}$ 46·15, $\dot{\mathrm{Ce}}$ 3·87, Ce 21·12, $\ddot{\mathrm{C}}$ 20·20, F 8·78=100. Analysis by Nordenskiöld (l. c.)—

$\ddot{\mathrm{C}}$	La	$\dot{\mathrm{Ce}}$	$\dot{\mathrm{H}}$	F—O
19·50	45·77	28·49	1·01	(5·23)=100

Nordenskiöld, having shown by direct determination that but 1·01 per cent. water exists in the mineral, and that the balance of loss on ignition is carbonic acid, finds, on recalculating Hisinger's early results with this correction, a close correspondence with the above, viz., $\dot{\mathrm{La}}$, $\dot{\mathrm{Ce}}$, 73·59, $\ddot{\mathrm{C}}$, $\dot{\mathrm{H}}$ 19·11, F—O, 5·76. $\ddot{\mathrm{Si}}$ 1·25=99·71. The direct determination of fluorine by Hisinger gave 9·95 per ct.

In the closed tube gives but little water, blackens, then becomes whitish-yellow and opaque; also gives a weak reaction for fluorine. Infusible. With acids effervesces slightly. With sulphuric acid gives off fluohydric acid, even after ignition. Found only at the Bastnäs Mine, Riddarhyttan, Sweden. The percentage composition brings this mineral near kischtimite (p. 703). It also resembles kischtimite in some of its physical characters, and further investigation may prove these minerals to be identical.

Barettite. A name given by Bombicci to a mineral from Traversella in the province of Ivrea, having the following characters:—Occurs in nodular, radiated, and fibrous masses. H.=2·5. G.=2·5. Color apple-green. Streak white. Feel soapy. Analysis gave $\ddot{\mathrm{Si}}$ 30·00, $\dot{\mathrm{Ca}}$ 33·70, $\dot{\mathrm{Mg}}$ 10·00, $\dot{\mathrm{Fe}}$ 7·20, $\ddot{\bar{\mathrm{Al}}}$ 1·60, $\ddot{\mathrm{C}}$ 9·1, $\dot{\mathrm{H}}$ 1·2, with a small amount of sulphuric acid, and probably also containing phosphoric acid and alkalies. (Atti della Soc. Ital. di Sc. Nat. xi., in Jahrb. Min., 1868, 750.

66 A. BEYRICHITE. *K. Th. Liebe*, Jahrb. Min., 1871, 840.

Hexagonal? Occurring in screw-shaped groups, radiated in structure, the constituent prisms of which are about 70 mm. long and 8 mm. wide. One terminal plane makes an angle of 81° with the vertical axis; a second, rarer, inclines to the first at an angle of 144°, the angle of the rhombohedron of millerite. Cleavage rather perfect parallel to the first of these planes, and no other cleavage direction observed, so that the rhombohedral character of the crystals is not certain.

H=3—3·5. G.=4·7. Lustre metallic. Color lead-gray. Composition $3\,\mathrm{Ni\,S}+2\,\mathrm{Ni\,S}^2$=S 43·21, Ni 56·79=100. An analysis by Liebe gave:

S	Fe	Ni
42·86	2·79	54·23=99·88

B. B. in the closed tube decrepitates and gives a sublimate of sulphur, on charcoal fuses to a brass-yellow magnetic globule. Soluble in nitro-muriatic acid, yielding an emerald green solution.

From Lammrichs Kaul Mine in Westerwald, where it is associated with millerite.

Bismutoferrite. *A. Frenzel*, J. pr. Chem., II., iv. 355. This name has been given to a so-called hypochlorite from Schneeberg, having H.=1–2. G.=4·47, and containing $\ddot{\mathrm{Si}}$ 23·08 $\ddot{\bar{\mathrm{Fe}}}$ 33·33, $\ddot{\bar{\mathrm{Bi}}}$ 43·26=99·67. Frenzel further distinguishes two varieties of hypochlorite, *antimony-hypochlorite* from Bräunsdorf, and *bismuth-hypochlorite* from Schneeberg; both of these are stated to be mixtures, and not homogeneous minerals.

189. *Chrompicotite.* *T. Petersen*, J. pr. Ch., cvi. 137.

A variety of chromite occurring in rounded octahedrons. H=8. G.=4·115. Lustre vitreous to greasy. Color black. Analysis by T. Petersen and K. Senfter (l. c.) afforded:

$\ddot{\bar{\mathrm{Cr}}}$	$\ddot{\bar{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Co}}$, $\dot{\mathrm{Ni}}$	$\dot{\mathrm{Mg}}$
56·54	12·13	18·01	0·46	tr.	14·08=101·22

This composition does not differ much from that of the magnesian alumina chromite from Baltimore, analyzed by Abich (Anal. 3. 4, p. 153), and that from Lake Memphramagog, examined by Hunt. If this variety is to have a new name it should have reference to chromite rather than picotite, a magnesia iron alumina spinel with only 7 per cent. of chromic oxyd. Its hardness is the chief character which favors its being classed with picotite.

From Dun Mountain, New Zealand.

554 C. COERULEOLACTITE. Cœruleolactin, *T. Petersen*, Jahrb. Min., 1871, 353.

Crypto-crystalline to micro-crystalline. Fracture uneven to conchoidal. H.=5. G.=2·552–2·593. Color milk-white passing into light copper-blue. Streak white. Composition: $\ddot{\bar{\mathrm{Al}}}^3$, $\ddot{\bar{\mathrm{P}}}^2+10\,\dot{\mathrm{H}}$=$\ddot{\bar{\mathrm{P}}}$ 36·74, $\ddot{\bar{\mathrm{Al}}}$ 39·37, $\dot{\mathrm{H}}$ 23·29. Analysis by Petersen (l. c.):

$\ddot{\bar{\mathrm{P}}}$	$\ddot{\bar{\mathrm{Al}}}$	$\ddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Cu}}$	$\dot{\mathrm{Zn}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\ddot{\mathrm{Si}}$	F	$\dot{\mathrm{H}}$
36·33	35·11	0·93	4·40	tr.	2·41	0·20	1·82	tr.	21·23=99·43

Excluding the iron (supposed to exist as limonite), the silica, and copper, lime and magnesia with sufficient phosphoric acid (=3·27 $\ddot{\bar{\mathrm{P}}}$) to make an ortho-phosphate, and calculating the remaining constituents (89·26 p. c.) up to 100 we have for the true composition of the mineral, according to Petersen, $\ddot{\bar{\mathrm{P}}}$ 37·04, $\ddot{\bar{\mathrm{Al}}}$ 39·34, $\dot{\mathrm{H}}$ 23·62, corresponding very closely with the above formula. B. B. decrepitates, infusible, on charcoal turns reddish-gray. With cobalt solution gives a deep blue. Moistened with sulphuric acid colors the flame green. With the fluxes gives a faint reaction for copper. Soluble in mineral acids, also in fixed caustic alkalies.

From the Rindsberg Mine near Katzenellnbogen, Nassau.

346. CYANOCHALCITE. *R. Hermann*, J. pr. Chem., cvi. 65.
Massive. H.=4·5. G.=2·79. Lustre glistening to dull. Color azure-blue. Fracture even and compact. Brittle. Analysis by R. Hermann:

$\ddot{\mathrm{Si}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dot{\mathrm{Cu}}$	$\dot{\mathrm{H}}$
26·90	6·95	49·63	16·52.

According to Hermann, this shows the composition to be equivalent to 1 atom of libethenite, and 9 atoms of chrysocolla. It is evidently a substance of like character with the demidoffite of Nordenskiöld. In the tube gives off water and becomes black. With the fluxes reacts for copper. Decomposed by acids without gelatinization.
Occurs at Nischne-Tagilsk.

452. *Diabantachronnyn*. A name given by Liebe (Jahrb. Min., 1870, 1) to a chlorite-like mineral occurring in the diabase of Voigtland and Frankenwald, and which contributes to the green color of the rock. It is found in seams and clefts, sometimes in amygdules and lining cavities in the rock. In some occurrences of diabase it forms the chief binding or cementing material, and is apparently a product of the alteration of the augitic constituent of the diabase. Compact, breaks with a conchoidal fracture, sometimes fibrous. Lustre dull. Color greenish-black, in thin splinters chrome-green. H.=2. G.=2·81–2·93. Composition, analyses by Liebe:

	$\ddot{\mathrm{Si}}$	$\overset{\cdots}{\mathrm{Al}}$	$\overset{\cdots}{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$
1. Reinsdorf	30·27	11·16	——	26·94	21·22	10·20=99·79
2. Landesfreude	29·37	12·00	——	25·63	21·01	11·27=99·28
3. Höllethal	29·85	9·07	——	26·60	17·92	15·81=99·25
4. Trilloch	31·25	10·03	3·47	23·52	19·73	11·37=99·37
5. Gräfenwart (fibrous)	31·56	12·08	——	21·61	22·44	11·78=99·47

Oxygen ratio for $\dot{\mathrm{R}}$, $\overset{\cdots}{\mathrm{R}}$, $\ddot{\mathrm{Si}}$, $\dot{\mathrm{H}}$ in the last analysis is 13·8 : 5·8 : 16·4 : 10·5. In the closed tube yields water. B. B. turns brown and fuses readily to a grayish-black glass, gives with salt of phosphorus reactions for iron and silica. Soluble in cold muriatic acid with deposition of pure white silica, with nitric acid gives off red nitrous fumes leaving a reddish-brown residue of silica.

113 A. DIAPHORITE. *V. v. Zepharovich*, Sitzb. Ak. Wien, lxiii. 130.
In endeavoring to ascertain the cause of the difference of the views of crystallographers in regard to the crystallization of freieslebenite, Zepharovich has discovered that the specimens referred to this species belong to two distinct crystalline systems, although chemically they are identical. He retains the name of freieslebenite for the monoclinic form, and names the new orthorhombic mineral *diaphorite*. The following planes were observed: $i\text{-}\breve{i}$, $i\text{-}\bar{i}$, $i\text{-}\bar{3}$, I, $i\breve{2}$-, $i\text{-}\frac{1}{8}^{2}$, $i\text{-}\breve{3}$, $i\text{-}\breve{5}$, $i\text{-}\breve{11}$, $\frac{1}{2}\text{-}\bar{i}$, $1\text{-}\bar{i}$, $\frac{1}{2}\text{-}\breve{i}$, $1\text{-}\breve{i}$, $\frac{3}{2}\text{-}\breve{i}$, $\frac{5}{3}\text{-}\breve{i}$, $2\text{-}\breve{i}$, $\frac{3}{4}\text{-}\breve{3}$, $\frac{5}{4}\text{-}\breve{\frac{5}{3}}$, $\frac{1}{4}$, $\frac{1}{2}$, $1\text{-}\breve{2}$ $\frac{3}{4}\text{-}\breve{3}$, 1-4. Cleavage not observed. Fracture uneven to sub-conchoidal. H.=2·5–3. G.=5·902, (Freieslebenite G.=6·35). Lustre metallic. Color steel-gray. Brittle. An analysis of the mineral from Przibram gave Helmhacker (B. and H. Jahrb. xiii. 379):

S	Sb	Pb	Ag	Fe	Cu
20·18	26·43	28·67	23·44	0·67	0·73=100·12

corresponding closely with the earlier analysis by Payr (this Min. Anal. 4. p. 93). These analyses Zepharovich refers to diaphorite, as no freieslebenite occurs at Przibram. The pyrognostic characters of both species are the same. Diaphorite occurs at Przibram and Bräunsdorf exclusively, while at Freiberg it is found with freieslebenite. The name diaphorite was formerly used for an altered rhodonite related to allagite.

503 A. DURANGITE. *G. J. Brush*, Am. J. Sci., II. xlviii. 179, Sept., 1869.
Monoclinic. Form of crystal like that of keilhauite (p. 387), omitting O and $-2i$, and adding $4i$. Cleavage parallel to I, distinct, giving 110° 10′, J. M. Blake. H.=5. G.=3·95–4.03. Lustre vitreous. Color bright orange-red. Streak cream-yellow. Analysis, G J. Brush (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{As}}$	$\overset{\cdots}{\mathrm{Al}}$	$\overset{\cdots}{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{Li}}$	F—O
55·10	20·68	4·78	1·30	11·66	0·81	(5·67)=100
53·22[a]	20·09	5·06	1·28	1 ·86	0·70	——

[a] Too low.

The oxygen ratio of $\dot{R}$, $\bar{R}$ and $\ddot{A}s$ is 3·74 : 11·07 : 19·16, or nearly 1 : 3 : 5, giving the formula $(\frac{1}{4}\dot{R}^3 + \frac{3}{4}\bar{R})\ddot{A}s$, in which a portion of the oxygen is replaced by fluorine.

In the closed tube blackens at a moderate temperature, but regains its color on cooling; at a higher heat fuses easily to a yellow glass and gives a faint white volatile sublimate, etching the tube slightly. The same in the open tube, with evolution of acid fumes, reddening litmus paper. On charcoal, B. B. fuses readily and gives a white sublimate with a strong arsenical odor in R. F. With soda and charcoal powder in a matrass yields a sublimate of metallic arsenic. With the fluxes reacts for iron and manganese. In the forceps fuses at 2, giving an intense soda flame. Decomposed by sulphuric acid with evolution of fluohydric acid.

Found near Durango in Mexico. The chemical composition of this mineral places it near amblygonite, an analogous fluo-phosphate, although the form of durangite is monoclinic while amblygonite is triclinic.

35. *Dyscrasite.* *T. Petersen* (Pogg. Ann., cxxxvii. 377), in a review of the analyses of dyscrasite, endeavors to show that there are two native compounds of antimony and silver, to one of which he gives the name *stibiotriargentite* ($Ag^3 Sb^2$), and the other, *stibiohexargentite* $Ag^6 Sb^2$. The former has a density of 9·611–9·77, and the latter 10·027. All recorded analyses that do not give one of these formulas he considers either to be erroneous or to have been made on a mixture of the above minerals.

617 A. **Eosite.** *A. Schrauf*, Min. Beobachtungen, ii. 20, in Sitzb. Ak. Wien, February, 1871.

Tetragonal, in minute octahedrons (¼ mm. diam.) a : b : c=1·3758 : 1 : 1. (Basal angle of octahedron 125° 40′). Inclination of basal plane to octahedral 117° 10′. H.=3–4. Color deep aurora-red, between that of crocoite and realgar, and much darker than red wulfenite. Streak brownish orange-yellow. Heated in the closed tube darkens, but regains its color on cooling. Fused with bi-sulphate of potash gives a mass which is light yellow while hot, becomes, on cooling, first reddish-brown and finally brownish orange-yellow. This dissolved in water and boiled with tin-foil colors the solution faint greenish-blue. Not so rapidly acted upon by muriatic acid as crocoite or wulfenite. When a splinter of eosite is placed on a glass plate, and treated with muriatic acid, with subsequent addition of alcohol, and then gently evaporated, it affords a blue to bluish-green coating, with a green precipitate on the edges. From these reactions, and a series of comparative tests made with crocoite, wulfenite, and vanadinite, Schrauf concludes that eosite is vanadio-molybdate of lead. Found implanted in very minute crystals on pyromorphite and cerussite at Leadhills, Scotland.

122 A. **Epiboulangerite.** *M. Websky*, ZS. G. Ges., 1869, p. 747.

Orthorhombic? occurring in striated prismatic needles G.=6·309. Lustre metallic. Color dark bluish gray, almost black. Structure granular, acicular. Analyses, 1, 2, Websky (l. c.):

	S	Sb	Pb	Ni	Fe	Zn
1. Granular.	21·89	20·77	56·11	0·20	0·60	0·29=99·86
2. Needles.	21·31	20·23	54·38	0·30	0·84	1·32=98·38

Websky considers the mineral as probably a product of the decomposition of Boulangerite, from which it differs in containing more sulphur and correspondingly less antimony. Found with galena, pyrite, blende, and mispickel, at Altenberg in Silesia.

132 A. **Epigenite.** *T. Petersen*, Pogg. Ann., cxxxvi. 502, Arsenikkupferwismuthers, Epigenit, *Sandberger*.

Orthorhombic, observed planes, *I*, 1-ĭ, 1-ī. $I \wedge$ 1-ī=110° 50′. H.=3·5. Lustre feebly metallic. Color steel-gray. Streak black. Fracture granular.

Composition $6R\,S + As^2\,S^5$. Analysis, Petersen (l. c.):

	S	As	Fe	Cu	Bi	Ag Zn
1.	31·57	12·09	13·43	40·32	2·12	tr.=99·53
2.	32·34	12·78	14·20	40·68=100·00		

No. 2 is No. 1 after deducting the 2·12 Bi which was present as intermingled wittichenite, and as such was combined with 1·84 Cu and 0·98 S. In the closed tube gives first sulphur then sulphid of arsenic. B.B. on charcoal gives an arsenic reaction and a magnetic slag with copper globules. Soluble in nitric acid with separation of sulphur.

Occurs sparingly at Neuglück Mine in Wittichen.

289. *Epiphanite.* *Igelström*, Œfv. Ak. Stockh., 1868, p. 29. This name has been given to a chlorite like mineral from Tväran in Wermland, Sweden. The composition Igelström found to be $\ddot{\rm Si}$ 37·10, $\overline{\overset{\dots}{\rm Al}}$ 21·18, $\dot{\rm Fe}$ 20·00, $\dot{\rm Mn}$ tr, $\dot{\rm Mg}$ 14·03, $\dot{\rm H}$ 7·83=100·09. It approaches Kenngott's eukamptite (p. 307) and gives the same formula plus one atom of water $\dot{\rm R}^3\,\ddot{\rm Si}+\overline{\overset{\dots}{\rm Al}}\,\ddot{\rm Si}+2\,\dot{\rm H}$.

449. *Euralite.* A name given by F. J. Wiik to a chloritic mineral occurring in seams in clefts of hyperite rock in the parish of Eura, Finland. It is apparently amorphous, but breaks under the hammer into prismatic fragments. H.=2·5. G.=2·62. Color dark-green to black. B. B. fuses easily to a magnetic globule. Soluble in muriatic acid. An analysis gave $\ddot{\rm Si}$ 33·68, $\overline{\overset{\dots}{\rm Al}}$ 12·15, $\overline{\overset{\dots}{\rm Fe}}$ 6·80, $\dot{\rm Fe}$ 15·66, $\dot{\rm Mg}$ 17·92, $\dot{\rm Ca}$ 1·34, $\dot{\rm H}$ 11·49=99·04. Wiik suggests that this composition is near delessite, which it also resembles in its mode of occurrence. (Jahrb. Min. p. 357.)

474. *Ferro-ilmenite*, a name given to a variety of columbite from Haddam, Connecticut (Hermann, J. pr. Chem., II. ii. 118).

93 A. GLAUCOPYRITE. *F. Sandberger*, J. pr. Chem., II. i. 230. Orthorhombic. Planes *i-i*, *I*, *m-i*. H.=4·5. G.=7·181. Lustre metallic. Color light lead-gray to tin-white Streak grayish-black. Composition $\rm Fe\,S^2+12\,(Fe,\ Co,\ Cu)\,(As,\ Sb)^2$=S 2·47, As 69·45, Fe 28·08. Analysis R. Senfter (l. c.):

S	As	Sb	Fe	Co	Cu
2·36	66·90	3·59	21·38	4·67	1·14=100·04

In the closed tube gives a sublimate of arsenic with only a small amount of sulphid. B. B. on charcoal gives arsenic fumes with an antimony coating. After roasting yields with soda a magnetic slag with spangles of metallic copper. With the fluxes reacts for iron and cobalt. Decomposed by nitric acid leaving a residue of antimonic acid. Found in the mines of Guadalcanal in Andalusia, Spain. Belongs near Lölingite, p. 77.

Guano Minerals. C. U. Shepard, Rural Carolinian, i. 470. The substances described occur in the guano of Guanape Island, 400 miles north-east of the Chincha Islands.

Guanapite occurs in irregular balls and veins looking like red rock-salt but having a rhombic cleavage. H.=1–2. G.=2·3. Soluble in 4–5 pts. of water at 60°. Taste bitter and saline. Analysis gave sulphate of potash 67·75, sulphate of ammonia 27·88, oxalate of ammonia 3·75=99·38. It loses ammonia on exposure to the air. Heated to redness leaves a residue of about 70 pr. ct. of sulphate of potash. It is near Taylorite (p. 614) in composition. *Guanoxalate* is stated to be a pseudomorph of birds' eggs; the specimens are exteriorly white, "and seem to retain portions of the original shell, but these when tested seemed to be a mixture of phosphate and oxalate of lime." Within the substance is foliated and has a rhombic cleavage. Color cream white; lustre pearly; translucent. H.=1–2. G.=1·58. When heated swells up, turns black, partially fuses, gives off ammonia fumes, and leaves a white residue of sulphate of potash. Composition stated to be sulphate of potash 40·20, oxalate of ammonia 29·57, water 30·46=100·23—a very doubtful compound. *Oxammite*, *phosphammite*, and *biphosphammite* are other names given by Shepard for supposed new species consisting of oxalate of ammonia, phosphate of ammonia, and biphosphate of ammonia.

422 A. GÜMBELITE. *F. von Kobell*, Ber. Ak. München, March 5th, 1870.

In thin, short fibrous layers in clay slate. Color light greenish-white. Translucent. Lustre pearly. Soft and flexible. Analysis, v. Kobell (l. c.):

$\ddot{\rm Si}$	$\overline{\overset{\dots}{\rm Al}}$	$\overline{\overset{\dots}{\rm Fe}}$	$\dot{\rm Mg}$	$\dot{\rm K}$	$\dot{\rm H}$	X (a)
50·52	31·04	3·00	1·88	3·18	7·00	1·46=98·08.

(a) Undecomposed mineral.

The oxygen ratio of $\dot{\rm R}$, $\overline{\overset{\dots}{\rm R}}$, $\ddot{\rm Si}$ and $\dot{\rm H}$ is as 1 : 12 : 21 : 5, which scarcely leads to a satisfactory formula. In the closed tube yields water. B. B. exfoliates somewhat like pyrophyllite. Fuses at 4. Not acted upon by acid.

Found at Nordhalben near Steben, in Oberfranken. The composition approaches that of pinite or neurolite (p. 482).

Hallite. A name given by A. R. Leeds to a flexible micaceous mineral of a brown color occurring in Chester Co., Pa., and supposed to possess distinguishing optical properties (Jour. Frank. Inst., III. lxii. 70.)

Hamartite. See Bastnaesite.

259 A. HORTONOLITE. *G. J. Brush*, Am. J. Sci. II., xlviii. 17., July, 1869.

Orthorhombic. Observed planes *O*, *i*-ĭ, *i*-2̆, 1-ī, 1-ĭ, 1-2̆ and 1-4 (J. M. Blake, l. c.), *i*-ĭ ∧ *i*-ī =65° (normals) 1-4 ∧ *i*-ĭ=77°–80°, *i*-ĭ ∧ 1-2̆=69°–70°. *i*-ĭ ∧ 1-ĭ 40' 45'. Acute bisectrix perpendicular to *i*-ĭ, optic axes in a plane parallel to *O*, angle between axes 83°–86, measured in olive oil (J. M. Blake). H.=6·5. G.=3·91. Lustre vitreous, subresinous. Color yellow to yellowish-green, in large masses almost black. Composition $\dot{\mathrm{R}}^2\,\ddot{\mathrm{Si}}$. Analysis, W. G. Mixter (l. c.):

$\ddot{\mathrm{Si}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{K}}$	Ign.
33·59	44·37	4·35	16·68	tr.	0·39	0·26=99·64

B. B. in the open tube and on charcoal becomes dull and magnetic. F=4. With the fluxes reacts for iron and manganese. Gelatinizes with muriatic acid.

Found in abundance at the O'Niel Mine, Orange Co., N. Y., associated with magnetite and calcite. The mineral is a member of the chrysolite group, and is intermediate between hyalosiderite and fayalite.

Hypochlorite. See Bismutoferrite.

224 A. ILSEMANNITE. *H. Höfer*, Jahrb. Min., 1871, p. 566.

Crypto-crystalline. Color blue-black to black, on exposure becoming blue. Found imbedded in barite. It is soluble in water, giving a deep-blue solution, and leaving a colorless residue of barite. The solution contained on analysis chiefly a molybdate of molybdic oxyd, and yielded on evaporation deep-blue crystals, which were considered to be the salt $\ddot{\mathrm{Mo}}$ + 4 $\dddot{\mathrm{Mo}}$, which is also supposed to be the composition of the mineral. Ilsemannite is a product of the decomposition of metallic molybdates, and occurs associated with wulfenite at Bleiberg in Carinthia.

431 A. IVIGTITE. *T. D. Rand*, Proc. Acad. Sci. Philad., 1868, 142.

In films and seams in massive cryolite. Granular, approaching micaceous. H.=2–2·5. G.=2·05. Color pale yellowish-green to yellow (Rand). Also in gold yellow to pale green radiated elastic plates imbedded in cryolite (Hagemann). Analyses: 1. T. D. Rand (l. c.); 2. 3. G. Hagemann, Am. J. Sci., II. xlvii. 133:

	$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\overline{\mathrm{Fe}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	F	$\dot{\mathrm{H}}$
1.	36·49	24·09	7·54	16·03	—	0·75	3·42
2. Yellow	40·00	38·47		10·27	1·05	tr.	3·06
3. Green	42·82	27·03	13·06	*undet.*	*undet.*	tr.	3·93

The loss in No. 1, exclusive of fluorine, is 11·68 per cent., while the average of Nos. 2 and 3 gives a loss of almost 5 per cent. In the closed tube yields acid water, and B. B. according to Rand fuses easily, while Hagemann states that when free from cryolite it does not fuse. With the fluxes gives iron and silica reactions.

Found with pachnolite and cryolite in the Greenland cryolite. Hagemann's analysis of the green mineral, which he considers the purest variety, gives with the alkalies of No. 2 the oxygen ratio of $\dot{\mathrm{R}}$, $\overline{\mathrm{R}}$, $\ddot{\mathrm{Si}}$ and $\dot{\mathrm{H}}$ of 1 : 6 : 8 : 1. Needs further investigation.

520 A. ISOCLASITE. Isoklas, *F. Sandberger*, J. pr. Chem., II. ii. 125.

Monoclinic. Occurring planes *I*, *i*-ĭ, *O*. Planes dull; crystals minute (10 mm. diam.), Associated with pseudomorphic crystals 3·7 c. m. long. Habit columnar. Clinodiagonal cleavage perfect. H.=1·5. G.=2·92. Lustre vitreous to pearly. Colorless to snow-white Composition: Var. 1. fresh crystals; 2. altered mineral, by Köttnitz, l. c.:

	$\ddot{\overline{\mathrm{P}}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\overline{\mathrm{Fe}}\ \overline{\mathrm{Al}}$	$\dot{\mathrm{H}}$(a)	$\dot{\mathrm{H}}$(b)	Ins.
1.	29·90	49·51		—	——	2·06	18·53	——=100·0
2.	34·00	1·00	17.30	9·80	0·36	24·26	9·22	0·18=96·12

(a) at 100° C., (b) on ignition.

The fresh crystals give the formula $\dot{\mathrm{Ca}}^3\,\ddot{\overline{\mathrm{P}}} + \dot{\mathrm{Ca}}\,\dot{\mathrm{H}} + 4\dot{\mathrm{H}}$. Analogous in composition to tagilite, but containing more water.

In the closed tube both varieties give off neutral water. B. B. the fresh mineral glows and fuses. Soluble in muriatic acid.

Found with hornstone and brown-spar on specimens from Joachimsthal, obtained eighty years ago, and now in the Würzburg Museum.

188 A. JACOBSITE. *A. Damour*, C. R., lxix. 168.

Isometric, in distorted octahedrons, H.=6? (scratches glass). G.=4·75. Lustre brilliant metallic. Color deep black. Streak blackish-brown. Magnetic.

Composition: $\dot{\text{R}}$, $\overline{\text{R}}$, or ($\dot{\text{Mn}}$ $\dot{\text{Mg}}$) ($\overline{\text{Fe}}$ $\overline{\text{Mn}}$)

	$\overline{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$
½	68·25	24·35	6·41=99·01

As the mineral evolves chlorine feebly when acted upon by muriatic acid, Damour considers a portion of the manganese to exist as $\overline{\text{Mn}}$, giving for the true composition of the mineral, in correspondence to the spinel formula, $\overline{\text{Fe}}$ 68·25, $\overline{\text{Mn}}$ 4·21, $\dot{\text{Mn}}$ 20·57, $\dot{\text{Mg}}$ 6·41=99·44.

B. B. infusible. It does not lose weight when ignited. With the fluxes reacts for iron and manganese. Soluble in muriatic acid, with a slight evolution of chlorine.

From Jacobsberg, in Nordmark, Sweden, where it occurs associated with white mica and native copper in a crystalline limestone

127 A. JULIANITE. *M. Websky*, ZS. G. Ges., 1871, p. 486.

Isometric. Cubic with octahedral and dodecahedral planes. Also dodecahedral. Planes much rounded.

G.=5·12. Very soft. Lustre metallic-adamantine. Color dark, somewhat reddish lead-gray, iron black on exposure. Brittle. Fracture splintery to subconchoidal.

Analysis by Websky (l. c.):

S	As	Sb	Fe	Ag	Cu
26·50	16·78	1·42	0·79	0·54	52·30=98·33

Giving a composition approaching tennantite or enargite. It agrees with the former in crystalline form, but differs in density from both these species.

B. B. Same as tennantite. Found in the Frederick-Julian Mine at Rudelstadt, in Silesia.

121 A. KLAPROTHOLITE. Klaprothit, *Petersen* and *Sandberger*, Jahrb. Min., 1868, 415. Klaprotholite, *G. J. Brush*.

This name is given to the Kupferwismuthers analyzed by Schneider, and recorded in this Mineralogy under Wittichenite, p. 99, anal. 7. Sandberger gives the following characters:—Orthorhombic, habit in long furrowed prisms. Planes *I*, *i-ī*, *m-ī*; $I\wedge I=107°$. Cleavage *i-ī* very distinct. In twins, composition-face *I*. Fracture granular. H.=2·5. G.=4·6 approx. (Petersen). Lustre metallic. Color steel-gray inclining to yellow, tarnishing brass-yellow. Streak black. Composition, $3\,\overline{\text{Cu}}\,\text{S}+\overline{\text{Bi}}^2\,\text{S}^3$=S 19·22, Bi 55·54, Cu 25·24=100. The mean of three analyses by Petersen gave, on mineral from the Daniel Mine, S 18·66, Bi 53·87, Cu 23·96, Fe 1·70=98·19. Occurs at many localities in the Black Forest, and distinguished from wittichenite by its distinct cleavage, and in its larger content of bismuth. Klaprotholite is generally associated with a cobalt-tetrahedrite, while wittichenite is usually found with smaltite. The name klaprothite was given to lazulite by Beudant in 1824, we therefore change Petersen's name to klaprotholite.

483 A. KOCHELITE. *M. Websky*, ZS. G. Ges., xx. 250, 1868.

Tetragonal? In columnar incrustations passing into rounded, apparently square octahedrons, occasionally showing prismatic planes. Color brownish isabella-yellow to honey-yellow. Translucent. Lustre dull greasy. H.=3–3·5. G.=3·74, taken on 0·1373 grm.

Composition. An imperfect analysis gave $\ddot{\text{Si}}$ 4·49, $\overline{\text{Al}}$ 1·41, $\overline{\text{Cb}}$ 29·49, $\ddot{\text{Zr}}$ 12·81, $\ddot{\text{Th}}$ 1·23, $\dot{\text{Y}}$ 17·22, $\dot{\text{Ca}}$ 2·10, $\overline{\text{U}}$ 0·43, $\overline{\text{Fe}}$ 12·48, $\dot{\text{H}}$ 6·52, $\dot{\text{Pb}}$? $\dot{\text{Na}}$? Loss 11·82=100.

In the closed tube yields water, and the mineral turns reddish. B. B. in the forceps fuses only on the edges to a black glass, coloring the flame yellow. With salt of phosphorus reacts for iron, but in R. F. fuses to a clear bead, showing only a faint reaction for uranium. With soda on charcoal yields a yellowish-white enamel, but no metallic globules, although giving a lead coating on the coal. Occurs as an incrustation upon a mixture of titanic iron and crystals of fergusonite in a coarse granite in the Kochelwiesen, near Schreiberhau in Silesia.

The composition is near that of fergusonite, but further investigation is needed. The density is remarkably low for a mineral containing so large a percentage of metallic acids.

518 A. *Kollophan.* This name has been given by Sandberger to a gymnite-like looking substance found with Sombrero guano. It is a tri-basic phosphate of lime with one atom of water, mixed with about 8 per cent. of carbonate of lime. G.=2·70. H.=5. J. pr. Chem., II. ii. 129.

644 A. LAXMANNITE. *A. E. Nordenskiöld*, Pogg. Ann., cxxxvii. 299, 1869.

Monoclinic. C.=69° 46′. *a*:*b*:*c*=1·3854:0·7400:1. Occurs in wedge-shaped forms with sharp edges. H.=3. G.=5·77. Color dark olive-green to pistachio-green and greenish-gray. Streak pistachio-green. Fracture, crystalline to compact and earthy. Composition $(\tfrac{2}{3}\dot{\mathrm{Cu}}+\tfrac{1}{3}\dot{\mathrm{H}})^3\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+3(\dot{\mathrm{Pb}},\dot{\mathrm{Cu}})^3\dddot{\mathrm{Cr}}=\dot{\mathrm{Pb}}$ 61·48, $\dot{\mathrm{Cu}}$ 13·13, $\dddot{\mathrm{Cr}}$ 16·57, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$ 7·83, $\dot{\mathrm{H}}$ 0·99=100 Analyses 1. 2. Nordenskiöld (l. c.):

	$\dddot{\mathrm{Cr}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dot{\mathrm{Pb}}$	$\dot{\mathrm{Cu}}$	$\overset{\cdot\cdot\cdot}{\mathrm{Fe}}$	$\dot{\mathrm{H}}$
1.	15·26	8·05	61·26	12·43	1·09	1·31=99·40
2.	16·76	8·57	61·06	10·85	1·28	0·90=99·42

Hermann has reviewed these results (J. pr. Chem., II. i. 447), and called attention to the close correspondence of this species in physical characters with vauquelinite, and also to the fact that the analyses were made on material from the very specimens from which Berzelius obtained the vauquelinite. By assuming that what Berzelius weighed as chromic acid was really phosphate of chromium, the results of the analysis are made to approximate very closely to those of Nordenskiöld; and Hermann believes that laxmannite is probably identical with vauquelinite. But Nordenskiöld shows in his investigation that there is associated with laxmannite a chromate free from phosphoric acid corresponding to the vauquelinite of Berzelius.

Hermann has also analyzed a phospho-chromate from Beresof, to which he gives the name *phosphochromite*, a mineral resembling *laxmannite* in physical characters, but containing

	$\dddot{\mathrm{Cr}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dot{\mathrm{Pb}}$	$\dot{\mathrm{Cu}}$	$\overset{\cdot\cdot\cdot}{\mathrm{Fe}}$	$\dot{\mathrm{H}}$
G.=5·80	10·13	9·94	68·33	7·36	2·80	1·16=99.72

This mineral occurs in rounded masses of half a pound weight, made up of globular particles, which exteriorly are covered with small tabular crystals with rounded terminations. It would seem possible that this aggregate might be a mixture rather than a distinct species; and this may perhaps also be true in regard to laxmannite. A chromo-phosphate of lead and copper from the same locality was described by John (this Min., p. 631) as early as 1845, but was thought to be an impure vauquelinite.

554. *Lime-Wavellite.* Kalkwavellit, *Kosmann*, Z. G. Ges., xxi. 795 (1869).

This name has been given to a mineral occurrring in concentric radiated spherical and hemispherical aggregations, sometimes in acicular crystals, as binding material in phosphorite-breccia; also found botryoidal and reniform. G.=2·45. Lustre feeble. Color white. Analysis, Kosmann (l. c.):

$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\dddot{\mathrm{Al}}$	$\overset{\cdot\cdot\cdot}{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$	$\ddot{\mathrm{Si}}$	$\ddot{\mathrm{C}}$	Ca Fl
24·10	30·26	0·29	16·16	0·12	3·58	0·89	17·90	3·59	2·78	0·37=100·04

Considering the carbonic acid to exist as carbonate of lime, and assuming the silica combined with the alkalies, Kosmann takes the remainder of the constituents $\dot{\mathrm{Ca}}$ 12·62, $\dddot{\mathrm{Al}}$ 30·26, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$ 24·11, and $\dot{\mathrm{H}}$ 17·90=84·88, and averages them up to 100 pts. as follows, $\dot{\mathrm{Ca}}$ 14·86, $\dddot{\mathrm{Al}}$ 35·65, $\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$ 28·39, $\dot{\mathrm{H}}$ 21·09=99·99, from which composition he concludes that the mineral is a *lime-wavellite*. In the closed tube yields water. B. B. fuses on the edges. Decomposed by muriatic acid with separation of gelatinous silica.

Found with phosphorite at Dehrn and Ahlbach. Needs further examination to determine its exact chemical composition.

218 D. LITHIOPHORITE (*Breithaupt*). *A. Frenzel*, J. pr. Chem., II. ii. 203 and iv. 353.

This is the substance already noticed by v. Kobell (Ber. Ak. München, Jan. 8, 1870, p. 49) as a lithia manganese ore in an examination of a so-called Asbolan from Saalfeld. Occurs in fine scales, also compact, botryoidal, H.=3. G.=3·65 (v. Kobell) 3·14—3.36 (Frenzel). Lustre dull to metallic. Color bluish-black. Streak blackish-gray. Composition: 1. 2. C. Winckler, J. pr. Chem., II. iv 353.

	$\overline{\rm Fe}$	$\overline{\rm Al}$	$\overline{\rm Mn}$	$\dot{\rm Cu}$	$\dot{\rm Co}$, $\dot{\rm Ni}$	$\dot{\rm Ba}$	$\dot{\rm Li}$	$\dot{\rm K}$	O	$\dot{\rm H}$	Ins
1.	1·48	10·54	55·12	1·74	2·42	2·78	1·23	0·73	10·28	12·64	— =98·96
2.	2·43	15·53	49·87	0·96	0·64 0·80	1·26	1·42	1·50	7·77	15·42	3·08=100·18

with traces of lime and bismuth. G. of No. 1=3·36, both specimens were from Schneeberg Saxony. In a partial analysis v. Kobell obtained (l. c.) $\overline{\rm Mn}$ 54·00, $\dot{\rm Co}$ 4·00, $\dot{\rm Cu}$ 0·61, $\overline{\rm Al}$ 23·00, $\dot{\rm H}$ 13.4.

Gives water in the tube. Infusible, colors the flame carmine-red. With the fluxes reacts for manganese; with salt of phosphorus in R. F. gives reactions for copper and cobalt. Soluble in muriatic acid with evolution of chlorine.

Found associated with quartz in many localities in the Schneeberg mining district, also occurs at Sayn, and near Siegen. Supposed to be a product of the decomposition of psilomelane. The large percentage of alumina and its content of lithia distinguish it readily from asbolite and lampadite.

598 A. *Lüneburgite.* O. Nöllner, Ber. Ak. München, 1870, 291.

This name has been applied by Nöllner to a salt from Lüneburg having the following composition: $\overline{\rm P}$ 29·8, $\overline{\rm B}$ 12·7, $\dot{\rm Mg}$ 25·3, $\dot{\rm H}$ 32·2=100. It also contains 0·7 Fl. Nöllner gives as formula for this substance (2 $\dot{\rm Mg}$, $\dot{\rm H}$) $\overline{\rm P}+\dot{\rm Mg}\,\overline{\rm B}+7\,\dot{\rm H}$. No physical characters are stated.

1 A. **MALDONITE.** *G. H. F. Ulrich*, Contrib. to Mineralogy of Victoria, 1870, (pamphlet 32 pp. 8vo.).

In small particles in quartz, cleavage apparently cubical. H.=1·5–2. G.=8·2–9·7? (made on less than one grain of impure mineral). Color pinkish-white, but tarnishing on exposure to copper-color and then black. Malleable. An assay by C. Newbery showed the composition to be Au 64·5, Bi 35·5, or nearly $\rm Au^2\,Bi$. B. B. fuses easily; on charcoal coats the coal yellow and yields a globule of gold.

From Nuggety Reef, Maldon.

64 A. **METACINNABARITE.** *G. E. Moore*, J. pr. Chem. II. ii. 319 (1870). Am. J. Sci. III. iii. 36.

Amorphous, also found in small apparently isometric crystals, perhaps pseudomorphic. H.=3. G.=7·70–7·748. Lustre metallic. Color grayish-black. Streak black. Fracture sub-conchoidal, uneven. Very brittle. Composition: Hg S. Analyses 1. 2., G. E. Moore (l. c.):

	S	Hg	Fe	quartz
1.	13·79	85·69	0·33	0·26=100·07
2.	13·84	85·89	0·45	0·24=100·42

Blowpipe characters like cinnabar. Occurs at the Redington Mine, Lake Co., California, with cinnabar, quartz and marcasite. It differs from cinnabar in its amorphous character, in color, streak, specific gravity and lustre, while in these respects it is identical with the black artificial mercuric sulphide of the laboratory.

MILARITE. *A. Kenngott*, Jahrb. Min., 1870, 81.

Hexagonal. Occurring form a hexagonal prism with a plane of a hexagonal pyramid on each angle, and a narrow termination of the lateral edges; observed angle over a terminal edge of the pyramid 144° 46½′ (mean of results), and over a basal edge 74° 40′; the latter gives for the former, by calculation, 144° 42′.

H.=5·5–6. Lustre vitreous. Colorless to greenish, resembling the datholite crystals from Bergen Hill. Brittle. B. B. in the closed tube becomes white and gives off water. In the forceps fuses with intumescence to a white blebby glass. In salt of phosphorus slowly but completely soluble to a colorless glass. A partial qualitative analysis gave evidence of the presence of an alkali and besides probably lime. Kenngott considers it a zeolitic hydrous silicate of alumina, lime, and soda, but on uncertain evidence.

Found in Val Milar near Ruäras, Switzerland.

503. *Montebrasite.* *Des Cloizeaux*, C. R. lxxiii. 306, 1247. *L. Moissenet*, Ann. d. Mines, VI x. 1 (1871). *F. Pisani*, C. R. lxxiii, 1479. *F. von Kobell*, Ber. Ak., München, Feb. 3, 1872.

This supposed fluo-phosphate from Montebras in France has recently been shown by Pisani and von Kobell to be identical with amblygonite. Des Cloizeaux found it to be triclinic, with two cleavages giving 105° 44′, and in the optical examination the bisectrix of the acute angle was positive, while in the Hebron amblygonite it is negative. Analyses by Moissenet (1). Pisani (2), and v. Kobell (3) afforded:

	F	$\overset{\dots}{\text{P}}$	$\overset{\dots}{\text{Al}}$	$\overset{\dots}{\text{Mn}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{Li}}$	$\ddot{\text{Si}}$	Ign.	
1.	26·50	21·80	38·20	—	2·00	6·70	6·50	2·25	0·60=104·55.	M
2.	8·20	46·15	36·32	0·40	—	2·58	8·10	—	1·10=102·85.	P.
3.	9·00	45·91	35·50	—	0·50	5·30	6·70	0·60	0·70—104·21.	K.

Pisani's and v. Kobell's results give essentially the composition of amblygonite as analyzed by Rammelsberg, and as the physical and pyrognostic characters are also those of amblygonite, there can be no question as to the identity of the Montebras mineral with this species.

MONZONITE. *F. v. Kobell*, Ber. Ak. München, 6 May, 1871.

Compact. H.=6. G.=3. Color light grayish-green. Translucent on thin edges. Fracture splintery to sub-conchoidal. Resembles green hornstone. Analysis by v. Kobell (l. c.):

$\ddot{\text{Si}}$	$\overset{\dots}{\text{Al}}$	$\overset{\dots}{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
52·60	17·10	9·00	2·10	9·65	6·60	1·90	1·50=100·45

Giving the oxygen of $\dot{\text{R}}$, $\overset{\dots}{\text{R}}$, and $\ddot{\text{Si}}$ as 1 : 1 : 3·5.

B. B. fuses at 3 to a lustrous grayish-green glass. Not decomposed by acids after fusion. Not attacked by muriatic or sulphuric acids. Soluble in concentrated phosphoric acid.

Found on the Monzoni Mt. in the valley of Fassa, Tyrol. A microscopic examination of a thin plate of the mineral showed it to be homogeneous.

Næsumite. *C. W. Blomstrand*, Œf. Ak. Stockh., 1868, p. 197.

A chalk-white mineral, from Näsum, Sweden. It occurs mixed with the phosphate attacolite. After calculating out the phosphoric acid as $\overset{\dots}{\text{Al}}\ \overset{\dots}{\text{P}}$, the analysis gave $\ddot{\text{Si}}$ 50·91, $\overset{\dots}{\text{Al}}$ 27·86, $\overset{\dots}{\text{Fe}}$ 1·36, $\dot{\text{Mn}}$ 0·36, $\dot{\text{Ca}}$ 13·82, $\dot{\text{H}}$ 4·39=98·70. The oxygen ratio of $\dot{\text{R}}$, $\overset{\dots}{\text{R}}$, $\ddot{\text{Si}}$, $\dot{\text{H}}$ is as 1 : 3 : 7 : 1. It may perhaps be classed near fahlunite.

510. **NADORITE.** *Flajolot*, C. R., lxxi. 237, 406. *F. Pisani*, C. R., lxxi. 319; *Des Cloizeaux*, Ann. d. M., VI. xx. 32, 1871.

In flattened tabular orthorhombic crystals, *I* ∧ *I*=132° 51′. Cleavage macrodiagonal, very easy. H.=3. G.=7·02. Lustre resinous to adamantine. Color smoky-brown to brownish-yellow. Streak yellow. Translucent. Analyses: 1. Pisani (l. c.); 2. Flajolot (l. c.):

	Sb	Pb	O	Cl
1.	31·24	51·89	8·14	9·00=100·27
2.	32·25	51·60	8·00	8·85=100·70

Pisani considers the mineral to correspond to the formula $\dddot{\text{Sb}}\ \dot{\text{Pb}} + \text{Pb Cl}$, while Flajolot looks upon it as a compound of oxychlorid of antimony with oxyd of lead. Pisani suggests its analogy with mendipite $2\ \dot{\text{Pb}} + \text{Pb Cl}$.

In the closed tube decrepitates and gives a white sublimate. B. B. on charcoal yields an antimony coating and a globule of metallic lead. Added to a bead of salt of phosphorus saturated with copper gives the blue coloration of the flame due to chlorid of copper. Soluble in muriatic acid; also in nitric acid diluted with tartaric acid.

From Djebel-Nador, in the province of Constantine, Algiers.

214 A. **NAMAQUALITE.** *A. H. Church*, Jour. Chem. Soc., II., viii. 1 (1870).

In silky fibres and thin layers. H.=2·5. G.=2·49. Lustre silky. Color pale-blue. Transparent to translucent. Analysis by Church (l. c.):

$\overset{\dots}{\text{Al}}$	$\dot{\text{Cu}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\ddot{\text{Si}}$	$\dot{\text{H}}$
15·29	44·74	3·42	2·01	2·25	32·38=100·09

Giving the oxygen ratio of $\dot{\text{R}}$, $\overset{\dots}{\text{R}}$ and $\dot{\text{H}}$ as 4 : 3 : 11, or $4\ \dot{\text{R}}\ \dot{\text{H}} + \overset{\dots}{\text{Al}}\ \dot{\text{H}}^3 + 4\ \dot{\text{H}}$.

In the closed tube gives off water and turns black. B. B. reacts for copper.

From Namaqualand, S. Africa. It is analogous in composition to hydrotalcite (p. 178).

146 A. **NANTOKITE.** An anhydrous sub-chlorid of copper from Nantoko in Chile. Occurs in a copper vein with atacamite and oxydized ores at the surface, while lower down in the vein this anhydrous chlorid is found with chalcopyrite and chalcocite. The mineral is white, resembles cerussite in physical characters. It oxydizes on exposure to the atmosphere, and is converted into atacamite. W. Hermann considers all atacamite the product of the alteration of nantokite (*Breithaupt* in B. and H. Ztg. xxvii. 3).

247 D. **NIGRESCITE.** *F. Hornstein*, ZS. G. Ges., 1867, 342.

Amorphous. Fracture uneven and splintery. H.=2. G.=2·845. Color, when fresh apple-green; on exposure becomes gray to black; opaque and earthy, and, on drying, as light as wad. Loses 16·5 per cent. hygroscopic water.

Analysis:

	$\ddot{\mathrm{Si}}$	$\dddot{\overline{\mathrm{Al}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\overline{\mathrm{H}}}$
§	52·29	5·14	15·71	0·23	18·11	2·59	6·29=100·36

Perhaps the product of the alteration of a magnesia-iron augite or amphibole.

Found in rounded masses in basalt, at Dietesheim, in the valley of the Maine.

Orileyite. *D. Waldie*, Proc. Asiatic Society, Bengal, p. 279. September, 1870.

Massive. H.=5·5. G.=7·34—7·42. Color steel-gray, on fresh fracture with purplish tint. Lustre metallic. Streak dark-gray. Analysis, D. Waldie (l. c.):

As	Sb	Cu	Fe	X	Insol.
38·45	0·54	12·13	42·12	6·19	0·12=99·55

X, oxydized matters soluble in dilute muriatic acid = $\dot{\mathrm{Cu}}$ 1·21, $\dot{\mathrm{Fe}}$ 1·97, $\dot{\mathrm{Pb}}$ 1·89, $\dddot{\overline{\mathrm{As}}}$ 1·12= 6·19. B. B. in the closed tube yields no arsenic. Soluble in nitric acid.

From Burmah, but exact locality not known. Needs further investigation.

Osbornite.—This name has been given by Maskelyne to small gold-yellow octahedrons occurring in augite in a meteorite from Busti, India. It is supposed to be an oxysulphid of titanium and calcium.

Phosphorchromite. See Laxmannite.

374. *Plumballophane.* A name given by Bombicci to a plumbiferous allophane from Monte Vecchio in Sardinia. Occurs in small stalactitic cylinders, rough and opaque on the surface, but interiorly glassy. Color grayish-yellow with a white streak. H.=2·5. G.=1·9. Analysis gave $\ddot{\mathrm{Si}}$ 23·8, $\overset{.....}{\overline{\mathrm{P}}}$ 2·6, $\dddot{\overline{\mathrm{Al}}}$ 32·9, $\dddot{\overline{\mathrm{Fe}}}$ 0·5, $\dot{\mathrm{Ca}}$ 2·4, $\dot{\overline{\mathrm{H}}}$ 35·2, $\dot{\mathrm{Pb}}$, $\dot{\mathrm{Mg}}$ and alkalies 2·5=99·9 (Atti della Sc. Ital. di Sc. Nat. xi., in Jahrb. Min. 1868, p. 750.

40 C. **POLYARGYRITE.** *F. Sandberger*, Jahrb. Min., 1869, 311. *T. Petersen*, Pogg. Ann., cxxxvii. 386. 1869.

Isometric. Observed planes 1 *O* *i*, *m-m*. Cleavage cubic. H.=2·5. G.=6·974. Lustre metallic. Color iron-black to dark blackish-gray. Streak black to blackish-gray. Malleable, flattening more under the hammer than argentite.

Composition: $12\ \mathrm{Ag\,S}+\mathrm{Sb_2S_3}$=Ag. 78·16, Sb 7·37, S 14·47=100·00.

Analysis, Petersen (l. c.):

	S	Sb	Ag	Pb	Fe	Zn
§	14·78	6·98	76·70	tr.	0·36	0·27*=99·09

* Corrected.

B. B. on charcoal fuses easily to a black globule, giving off antimony fumes, and yielding a brittle globule of silver. Soluble with difficulty in nitric acid with separation of sulphur. Fuming acid dissolves it readily with separation of antimonate of silver.

Occurs at Wolfach in Baden.

The mineral is between argentite and pyrargrite in composition. If homogenous it would be classified chemically near polybasite; but its isometric form, and the fact that in another analysis Petersen found 78·85 Ag, suggests that it may possibly be a mixture.

624. **PUCHERITE.** *A. Frenzel*, J. pr. Chem., II. iv. 227, 361.

Orthorhombic. Observed planes *I*, *O*, 1-ĭ, *m-u*. Cleavage basal. H.=4. G.=5·91. Lustre vitreous adamantine. Color reddish-brown. Streak yellow. Translucent to opaque. Composition: $\dddot{\overline{\mathrm{Bi}}}\ \overset{.....}{\overline{\mathrm{V}}}=\dddot{\overline{\mathrm{Bi}}}$ 71·67 $\overset{.....}{\overline{\mathrm{V}}}$ 28·33=100. Analyses, 1. 2. Frenzel (l. c.):

	$\overset{.....}{\overline{\mathrm{V}}}$	$\dddot{\overline{\mathrm{Bi}}}$
1.	27·31	73·39=100·70
2.	27·07	72·93=100 —

In the closed tube decrepitates. B. B. on charcoal fuses and gives a coating of bismuth-oxyd, with soda yields a globule of metallic bismuth. With salt of phosphorus a chrome-green bead in R. F. becoming light yellow in O. F. (vanadium). Soluble in muriatic acid with evolution of chlorine to a deep-red solution, which on dilution becomes green and deposits a yellow basic chlorid.

Named pucherite from the locality, the Pucher Mine, Schneeberg, Saxony. Found associated with bismite and asbolite.

218 B. RABDIONITE. *F. von Kobell*, Ber. Ak. München, January 8, 1870.

Stalactitic, in columnar or rod-like forms. Very soft, soiling the fingers. G.=2·80. Lustre dull, after rubbing is greasy to submetallic. Color black. Streak dark-brown. Composition·

$\bar{F}e$	$\bar{M}n$	$\bar{A}l$	$\dot{C}u$	$\dot{M}n$	$\dot{C}o$	$\dot{H}$
45·00	13·00	1·40	14·00	7·61	5·10	13·50=99·61

The oxygen ratio of $\dot{R}$: $\bar{R}$: $\dot{H}$ is 1 : 3 : 2, and v. Kobell writes the formula ($\dot{C}u$, $\dot{M}n$, $\dot{C}o$) ($\bar{F}e$, $\bar{M}n$) + 2 $\dot{H}$.

In the closed tube gives neutral water. B. B. fuses at 3 to a steel-gray, magnetic-globule, and colors the flame green. With borax gives a cobalt blue bead. Soluble in muriatic acid with evolution of chlorine, giving an emerald-green colored solution.

From Nischne Tagilsk in Ural. The mineral is near asbolite (p. 181), but differs from it in chemical composition, in containing a large percentage of iron, and in being easily fusible.

163 A. RALSTONITE. *G. J. Brush*, Am. J. Sci., III. ii. 30. July, 1871.

Isometric. Habit octahedral. Observed planes 1, *O* (this Min. fig. 7, p. 21). H.=4·5. G.=2·4 (on 25 milligrams). Composition, a hydrous fluorid of aluminum, with possibly small quantities of calcium and sodium.

In the closed tube whitens, yields water at first, then a copious white sublimate which etches the tube. The water reacts acid. B. B. on charcoal a faint white sublimate. In the forceps whitens, colors the flame yellow, but does not fuse. With cobalt solution gives a deep blue. In salt of phosphorus dissolves completely to a colorless bead in both flames. Soluble with effervescence in a carbonate of soda bead. Decomposed by sulphuric acid with evolution of fluohydric acid.

Occurs with cryolite and thomsenolite at Arksut Fiord, Greenland.

Redondite. A name given by C. U. Shepard to a hydrous phosphate of alumina and iron from Redonda, W. I. Found in nodular aggregations. Translucent to opaque. Color grayish to yellowish white. H.=3·5. G.=1·90–2·07. Specimen analyzed contained 8·8 per cent. $\ddot{S}i$, 40·192 $\dddot{P}$ and 24·73 $\dot{H}$ (Am. J. Sci. II. l. 96). An earlier analysis gave $\dddot{P}$ 43·20, $\bar{F}e$ 14·40, $\bar{A}l$ 16·60, $\dot{H}$ 24·00, $\ddot{S}i$ 1·60, $\dot{C}a$ 0.57=100·37, contained also traces of $\dddot{S}$, Na, Cl and $\dot{M}g$. B. B. infusible. Heated with solution of cobalt gives a deep blue color (Am. J Sci., II. xlvii. 428.

422. *Restormelite.* A name given by A. H. Church (Jour. Chem. Soc., II. viii. 166) to a massive grayish-green agalmatolite-like mineral from Restormel Mine in Cornwall. H.=2. G.=2·58. Mean results of analysis gave $\ddot{S}i$ 45·66, $\bar{A}l$ 35·10, $\dot{F}e$ 1·11, $\dot{M}g$ 0·85, $\dot{K}$ 2·30, $\dot{N}a$ 4·39, $\dot{H}$ 11·68=101·09. This composition is near that given by Lehunt and Blythe for killinite (anal. 29 and 30, under pinite, p. 481). Church does not consider the mineral worthy to rank as a distinct species, but speaks of it as an "*immature* kaolinite."

261 A. ROEPPERITE. Iron, manganese, zinc, chrysolite. *W. T. Roepper*, Am. J. Sci., II. l. 35. Roepperite, *G. J. Brush*.

Orthorhombic, observed planes *i*-2, *i*-ī, 1-ĭ, *i*-ĭ, 1-ī, 1-ĭ, *O*, 2-2. *i*-2 ∧ *i*-2 (over *i*-ī) 130°, *i*-ī ∧ *i*-2=115° 1-ĭ ∧ 1-ĭ=77°. Cleavage in three directions rectangular, *O* and *i*-ī eminent, *i*-ĭ splintery. H.=5·5–6. G.=3·95–4·08. Lustre on cleavage planes vitreous to subadamantine. Color dark-green to black, mottled. In thin splinters translucent and pale-yellow color. Streak yellow to reddish-gray. Slightly magnetic. Composition: $\dot{R}^2\ddot{S}i$. $\dot{R}$ =$\dot{F}e$, $\dot{M}n$, $\dot{Z}n$ and $\dot{M}g$. Analyses 1. 2. 3., W. T. Roepper (l. c.):

	$\ddot{S}i$	$\dot{F}e$	$\dot{M}n$	$\dot{Z}n$	$\dot{M}g$	Insol.*
1. Cryst.	30·76	33·78	16·25	10·96	7·60	——=99·35
2. Cryst. }	30·23	35·52	16·91	10·68	5·63	1·04=100.01
3. Mass. }	30·54	34·78	17·74	9·48	6·09	2·02=100·65

* Spinel.

B. B. fuses with difficulty on the thin edges to a black slag. With the fluxes reacts for iron, manganese, and silica; on charcoal with soda gives a zinc coating. Gelatinizes with acids readily and completely, leaving sometimes a bright-green residue of spinel.

Occurs at Stirling Hill, Sussex Co., N. J., with willemite, franklinite, jeffersonite, and spinel; also found at Franklin Furnace with gahnite.

393 A. *Reissite.* A name given by K. v. Fritzsch to a zeolitic mineral from Santorin According to Hessenberg (his Min. Notizen, No. 9, p. 22) it is orthorhombic with the axial relation for the brachydiagonal, macrodiagonal, and vertical axis. 0·4231 : 1 : 0·2866. Observed planes *I*, *i*-ĭ, 1-ĭ, 2-ĭ. Cleavage brachydiagonal. Lustre vitreous. Colorless to white. Fusible with intumescence to a blebby enamel. Gelatinizes with acids more readily after fusion than before. The solution contains lime and alkalies. Hessenberg considers it probable that reissite is identical with Breithaupt's species monophane, and distinct from epistilbite.

125. *Rionite.* A name given by Brauns to a bismuth-tetrahedrite from Cremenz, Einfischthal in Wallis Canton, Switzerland. It has a conchoidal fracture, an iron-black color, black streak, and greasy-metallic lustre. An analysis gave S 29·10, As 11·44, Sb 2·19, Bi 13·07, Cu 37·52, Ag 0·04, Fe 6·51, Co 1·20=101·07. Found associated with chalcopyrite. It is worked as an ore of bismuth. The composition places it near annivite, p. 108. (T. Petersen in Jahrb. Min., 1870, 590).

The name *Rionite* was used formerly for a supposed selenid of zinc, described by Del Rio, and *Riolite* for a supposed selenid of silver as well as the preceding, but both names have been dropped from the science, the material on which they were founded being only a mixture.

807 A. ROSTHORNITE. *H. Höfer*, Jahrb. Min., 1871, p. 561.

In lenticular masses in coal. G.=1·076. Lustre greasy. Color brown, with garnet-red reflections: in thin splinters wine-yellow. Composition : $\not{\mathrm{C}}_{24}\,\mathrm{H}_{40}\,\not{\mathrm{O}}$. Analysis by Mitteregger (l. c.):

	C	H	O
½	84·42	11·01	4·57=100·00

At 96°C. commences to melt to a viscous brownish-red mass, which at 160° gives off bubbles and at 205° white fumes, heated to 225° the evolution of gas ceases, leaving a thin dark purplish-red fluid. Insoluble in dilute nitric acid as also in potash or alcohol. Slightly soluble in warm ether and entirely so in warm oil of turpentine. Completely soluble in benzole at ordinary temperatures. From Sonnberge, Carinthia. Resembles jaulingite in physical characters, while it is near euosmite in chemical composition.

499. SARCOPSIDE. Sarkopsid, *M. Websky*, ZS. G. Ges., xx. 245, 1868.

Monoclinic? occurring in irregular ellipsoids, sometimes in distorted six-sided plates.

H.=4. G.=3·692—3·730. Lustre glistening to silky and greasy. Color, on fresh surface, flesh-red to lavender-blue. Translucent in thin splinters. Streak straw-yellow, some grains give a green color. Composition : $4\dot{\mathrm{R}}^{3}\,\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}+(\mathrm{R\ Fl}+\not{\mathrm{H}}\,\dot{\mathrm{H}})$ Websky :

	$\overset{\cdot\cdot\cdot\cdot\cdot}{\mathrm{P}}$	$\overset{\cdot\cdot\cdot}{\not{\mathrm{F}}\mathrm{e}}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{n}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{H}}$	Fl
½	34·73	8·83	30·53	20·57	3·40	(1·64)	undet.

In the closed tube gives water which reacts for fluorine, turns dark-brown and assumes a sub-metallic lustre. Fuses very easily, may be melted to a bead on platinum wire, and this imparts a blue-green color to the outer flame. With the fluxes reacts for iron and manganese, and fused with bi-sulphate of potash in a closed tube reacts for fluorine, coloring brazil-wood paper and etching the tube. Soluble in dilute muriatic and sulphuric acids.

Occurs with vivianite and hureaulite in a granite vein on a ridge between Michelsdorf and the valley of the Mühlbach in Silesia. This mineral corresponds so closely to triplite (p. 543) in chemical composition and pyrognostic characters, as also in density and hardness, as to make it exceedingly probable that it may be a variety of that species.

163 B. SELLAITE. *Strüver*, Atti della R. Accad. di Torino, iv. 1868, 35.

Tetragonal, *I* on 1=123° 30′, *i*-*i* on *i*-3 161° 34′. Cleavage parallel to *I* and *i*-*i* perfect. H.=5. G.=2·972. Lustre vitreous. Fracture conchoidal. Colorless. Transparent. Composition : MgFl? In small fragments melts in the flame of a candle with intumescence. Insoluble in water, also in acids, except concentrated sulphuric acid, with this it evolves fluohydric acid. The sulphuric solution gave 39·64 pr. ct. of magnesia, which with the other chemical and physical properties of the mineral leads Strüver to consider the mineral a fluorid of magnesium analogous to fluorite in composition.

Found with anhydrite at Geibroula in Piedmont.

659 A. SIMONYITE. *G. Tschermak*, Ber. Ak. Wien, November Heft, 1869.

Monoclinic. Ratio of orthodiagonal, clinodiagonal, and vertical axis 1 : 0·7453 · 0·5041 ; in

clination of axis=C=101° 29′. Observed planes *I*, *O*, *i*-2, 1, 1-*i*. *I*∧*I*=105° 15′, *O*∧1-*i*=146° 38′, *O*∧1=142° 5′, *I*∧ *i*-2=160° 34′. Crystals minute. Also massive. H.=2·5. G.=2·244. Color of the massive mineral bluish-green to reddish-yellow. The crystals sometimes colorless and transparent. Taste faint, saline, and bitter. Unaltered on exposure to the air.
Analysis: G. Tschermak (l. c.):

$\bar{\mathrm{S}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
47·17	12·65	18·86	21·82=100·50

This yields the oxygen ratio for $\dot{\mathrm{R}}$: $\bar{\mathrm{S}}$: $\dot{\mathrm{H}}$, 1 : 3 : 2 or $\dot{\mathrm{R}}\,\bar{\mathrm{S}} + 2\dot{\mathrm{H}}$, the same as the formula given for Blœdite (p. 643), which mineral it also resembles in crystalline form. Tschermak remarks that simonyite differs from blœdite in not efflorescing on exposure to air, and losing only a portion of its water (4·90 pr. ct.) on being heated for two hours in a water-bath. Occurs at Hallstadt.

A mineral of the same composition and form, likewise unalterable in air, found at Stassfurth, has been referred by Groth and Hintze to blœdite, these authors assuming that the efflorescence of blœdite, noticed by earlier observers, was due to mixture with some efflorescent salt. ZS. G. Ges. 1871, 870.

Stibiotriargentite, *Stibiohexargentite*, see Dyscrasite.

595 A. SUSSEXITE. *G. J. Brush*, Am. J. Sci., II. xlvi. 140, 240, 1868.
In fibrous seams or veins. H.=3. G.=3·42. Lustre silky to pearly. Color white with a tinge of pink or yellow. Translucent.
Composition: $(\dot{\mathrm{Mn}}, \dot{\mathrm{Mg}})^2\,\bar{\mathrm{B}} + \mathrm{H}$ or $(\frac{2}{3}(\dot{\mathrm{Mn}}, \dot{\mathrm{Mg}}) + \frac{1}{3}\dot{\mathrm{H}})^3\,\bar{\mathrm{B}}$. Analysis: G. J. Brush (l. c.):

$\bar{\mathrm{B}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$
31·89	40·10	17·03	9·59=98·61

In the closed tube darkens in color and yields neutral water. If turmeric paper is moistened with this water, and then with dilute muriatic acid, it assumes a red color (boric acid). In the forceps fuses in the flame of a candle (F=2), and B. B. in O. F. yields a black crystalline mass, coloring the flame intensely yellowish-green. With the fluxes reacts for manganese. Soluble in chlorhydric acid.

Found on Mine Hill, Franklin Furnace, Sussex Co., N. J., associated with franklinite, zincite, willemite, and other manganese and zinc minerals. This species approaches in composition the mineral szaibelyite.

TALCOSITE. *G. H. F. Ulrich*, Contributions to the Mineralogy of Victoria, Melbourne, 1870 (pamphlet of 32 pp. 8vo.).
In thin seams and threads with scaly structure, the scales apparently rhombic plates. H. =1–2. G.=2·46–2·5. Lustre pearly. Color silver-white, faint greenish, or yellowish. Scales flexible but not elastic. Resembles talc. Analyses 1. 2 by C. Newbery (l. c.):

	$\ddot{\mathrm{Si}}$	$\ddot{\overline{\mathrm{Al}}}$	$\ddot{\overline{\mathrm{Cr}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{H}}$
1.	49·01	45·10	tr.	tr.	tr.	tr.	4·98=99·09
2.	49·07	46·96	tr.	tr.	tr.	tr.	3·73=99·76

The oxygen ratio of anal. 1 for $\dot{\mathrm{H}}$, $\ddot{\overline{\mathrm{Al}}}$, $\ddot{\mathrm{Si}}$ is 1 : 5 : 6. This mineral is perhaps related to selwynite, with which it occurs, and also to westanite (described in this appendix).
Obs. From Mount Ida near Heathcote, Victoria.

Tellurwismuthsilber. *C. Rammelsberg*, ZS. G. Ges., xxi. 81.
Granular. G.=7·803. Lustre metallic. Color gray, tarnished. Cuts with a knife, but sufficiently brittle to be readily pulverized. Composition: analysis by Rammelsberg, l. c.:

S	Te	Bi	Ag	Cu
3·32	24·10	48·50	23·35	tr.=99·27

Rammelsberg gives the relation of S : Ag : Bi : Te as 1 : 2·08 : 2·24 : 1·8, but thinks it may be more correctly expressed by 1 : 2 : 2 : 2, as the bismuth obtained was not free from tellurium, and the formula of this new tellurium mineral may then be written $\mathrm{Ag^2\,S + Bi^2\,Te^2}$ or $\mathrm{Ag^2\,S + 2\,Bi\,Te}$?. He also questions whether the mineral may not be a mixture of argentite and tellurid of bismuth, or of native silver and sulphotellurid of bismuth, but finds nothing in the physical properties of the mineral to indicate a mixture.
Obs. From Sierra de Tapalpa, Mexico.

817 A. TRINKERITE. *G. Tschermak*, J. pr. Chem., II. ii. 258, and Jahrb. G. Reichs. 1870, xx. 279.

Compact and amorphous. H.=1·5—2. G.=1·025. Lustre greasy. Color hyacinth-red to chestnut-brown. Transparent to translucent. Analysis, 1. Hlasiwetz (l. c.); 2. Niedzwiedzki, Jahrb. Min., 1871, 641:

	C	H	S	O	Ash
1. Carpano	81·1	11·2	4·7	3·0	None=100
2. Gams	81·9	10·9	4·1	3·1	——=99·0

Fuses at 168°—180°C., at a higher temperature gives off choking fumes. Insoluble in water, and only slightly in alcohol and ether. Soluble in hot benzole.

Occurs in large compact masses in brown coal at Carpano near Albona in Istria; also found at Gams near Hieflau in Styria. Resembles in composition the tasmanite of Church (p. 746).

573 B. TRÖGERITE. *A. Weisbach*, Jahrb. Min., 1871, 870.

Monoclinic, in thin tabular crystals. Cleavage perfect, parallel to the broad tabular plane. G.=3·3. Lustre on the cleavage-plane pearly. Color lemon-yellow. Composition, $\bar{\text{U}}^3\,\ddot{\ddot{\text{A}}}\text{s}^1+20\,\dot{\text{H}}$ (Winckler). No analysis is given. Occurs with walpurgite and other uranium minerals at the Weisser Hirsch Mine in Neustädtel near Schneeberg, Saxony.

URANOTIL. *E. Boricky*, Jahrb. Min., 1870, 780.

Orthorhombic, in acicular crystals. Occurring form *I*, *i-ī*, *m-ī*; angle of prism *I* about 164° (Zepharovich). In radiated or stellated groups. Cleavage probably basic. G.=3·9595. Color lemon-yellow. Streak lighter. The mean of three analyses gave Boricky:

$\ddot{\text{Si}}$	$\bar{\text{U}}$	$\underbrace{\bar{\text{Al}}\ \bar{\text{Fe}}}$	$\dot{\text{Ca}}$	$\bar{\text{P}}$	$\dot{\text{H}}$
13·78	66·75	0·51	5·27	0·45	12·67=99·43

Giving a composition near that of uranophane (p. 805). It also resembles it in crystalline form, the angle of prism *I* of uranophane 146°, giving 162° for the prism *i*-2.

B. B. turns black. Soluble in warm muriatic acid with separation of flocky silica.

Found with fluorite, uranite, and quartz at Wölsendorf, Bavaria.

622 B. VANADIOLITE. *Hermann*, J. pr. Chem., II. i. 445.

Form not determined. Occurs in small crystals, partly in druses. Color dark-green, almost black, in small fragments dark emerald-green. Streak grayish-green. Lustre vitreous, brilliant. G.=3·96. Analysis gave

$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\dot{\text{Fe}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$	$\dddot{\text{V}}$
15·61	1·10	1·40	34·43	2·61	44·85=100.00

which Hermann considers as representing a compound of three atoms of augite, and one of subvanadate of lime. He gives for this the formula $3\dot{\text{R}}\,\ddot{\text{Si}}+\dot{\text{Ca}}^6\,(\text{VO}^4+2\text{VO}^5)$. B. B. fuses to a black slag with cauliflower-like intumescences. With salt of phosphorus gives a dark-green bead, and a silica skeleton. Decomposed on fusion with a mixture of carbonate of soda and nitre. From Slüdänka near Lake Baikal associated with lavroffite.—A substance containing as this does over 70 per cent. of a vanadate, with the balance a silicate corresponding to augite can scarcely be looked upon as a homogeneous simple mineral. It is here classed with the vanadates.

573 A. WALPURGITE. Walpurgin, *A. Weisbach*, Jahrb. Min., 1871, 870.

Monoclinic, in thin scaly crystals. G.=5·8. Lustre adamantine to greasy. Color pomegranate and wax-yellow. Composition $\bar{\text{R}}^4\,\ddot{\ddot{\text{A}}}\text{s}+5\dot{\text{H}}$ in which $\bar{\text{R}}=\frac{4}{5}\,\dddot{\bar{\text{B}}}\text{i}+\frac{1}{5}\,\bar{\text{U}}$ (Winckler). No analysis is given. Occurs with trögerite and other uranium ores at the Weisser Hirsch Mine in Neustädtel near Schneeberg, Saxony.

323 A. WESTANITE. *C. W. Blomstrand*, Œf. Ak. Stockh., 1868, p. 197, in J. pr. Ch., cv. 341.

In radiated crystalline masses, sometimes in prismatic crystals. H.=2·5. Color brick red. An analysis gave:

$\ddot{\text{Si}}$	$\bar{\text{Al}}$	$\bar{\text{P}}$	$\bar{\text{Fe}}$	$\dot{\text{H}}$
(42·53)	51·14	1·15	1·01	4·17=100·00
42·91	51·92		1·56	——

This composition is near wörthite, a hydrous fibrolite, but it differs from that mineral in inferior hardness.

B. B. swells up; infusible and turns white. Not acted upon by acids.

Associated with pyrophyllite at Westana, Sweden.

601 A. WINKWORTHITE. *H. How*, Phil. Mag., April, 1871.

In imbedded nodules, crystalline on fracture. Glistening. Colorless to white. Translucent. H.=2—3. Composition: analyses 1. 2., H. How, l. c.:

	$\ddot{Si}$	$\overline{B}$	$\dddot{S}$	$\dot{Ca}$	$\dot{H}$
1.	3·31	(10·13)	36·10	31·66	18·80=100
2.	4·98	(14·37)	31·51	31·14	18·00=100

In the closed tube gives water. B. B., decrepitates and fuses readily to a clear bead, coloring the flame green; on continued blowing froths, becomes opaque and no longer shows the green coloration.

Found in gypsum at Winkworth, Nova Scotia. How considers No. 1 to be represented by 11 $\dot{Ca}$, 1$\ddot{Si}$, 9$\dddot{S}$, 3$\overline{B}$ and 20$\dot{H}$, while No. 2 is the same with substitution of 8$\dddot{S}$ and 4$\overline{B}$. He suggests that the mineral is intermediate between selenite and howlite. May it not be a mixture?

92 A. WOLFACHITE. *F. Sandberger*, Jahrb. Min., 1869, 313.

T. Petersen, Pogg. Ann. cxxxvii. 397. Orthorhombic, in small crystals coating niccolite Observed planes *I*, *m*-ī. H.=5·5. G.=6.372. Lustre metallic. Color silver-white to tin-white. Streak black. Analysis by Petersen (l. c.):

S	As	Sb	Pb	Ag	Fe	Ni	Co, Cu, Zn
14·43	38·46	13·17	1·33	0·12	3·71	29·53	traces=100.74

The lead and silver were believed to be due to a small amount of intermingled galena and dyscrasite. The results give the formula $NiS^2 + Ni(As\,Sb)^2$ exactly the same as given for the isometric corynite (p. 74), showing this compound to be dimorphous. Corynite has a lower density (5·95—6·03) and less hardness (4·5—5.). The pyrognostic characters are the same for both minerals and both are soluble in nitric acid. From Wolfach in Baden.

830 B. *Wollongongite*. *B. Silliman*, Am. J. Sci., II. xlviii. 85.

This name has been given provisionally to a hydro-carbon from New South Wales. Occurs in cubical blocks, without lamination. Fracture broad conchoidal. Color greenish to brownish-black. Lustre resinous. Translucent in thin shavings, showing under the microscope an amber-yellow light.

Alone in the tube does not melt but decrepitates and gives off oil and gas. Ignites readily and yields, when heated out of access of air, 82·5 volatile matter, coke 6·5, and when burned 11·0 per cent of ash. Insoluble in ether and benzole, but slightly acted upon by bi-sulphid of carbon.

550 A. ZEPHAROVICHITE. *E. Boricky*, Sitzb. Ak. Wien, lix. 593, 1869.

Crystalline to compact, horn-like in aspect. H.=5·5. G.=2·37. Color greenish, yellowish or grayish-white. Translucent. Fracture conchoidal. Composition:

	$\dot{\overline{P}}$	$\overline{Al}$	$\overline{Fe}$	$\dot{Ca}$	$\dot{Mg}$	$\dot{H}$	Quartz
1.	35·56	29·77	——	1·07	0·41	26·70	5·46=98·97
2.	37·46	28·44	——	0.54	tr.	26·57	6·05=99·06
3.	37·80	29·60	0·85	1·38	——	28·98	0·46=99.07

Nos. 1 and 2 contained intermingled wavellite, and No. 3 an earthy gibbsite. Boricky thinks the analyses prove the mineral to be essentially a phosphate having the formula $\ddot{\overline{Al}}$ $\dot{\overline{P}} + 6\dot{H}$, and that in analysis 2 this phosphate is mixed with $\frac{1}{17}$ of wavellite, while in No. 3 is associated with $\frac{1}{10}$ of gibbsite and $\frac{1}{33}$ of tribasic phosphate of lime. The formula $\ddot{\overline{Al}}\,\dot{\overline{P}} + 6\dot{H}$ differs from Callainite (p. 572) only in containing 1 atom more of water, and analysis 2, after deduction of the 6·04 of quartz, gives $\dot{\overline{P}}$ 40·28, $\ddot{\overline{Al}}$ 30·57, $\dot{Ca}$ 0·58, $\dot{H}$ 28·56, a result which approaches the figures given by Damour in his analysis of callainite.

Occurs in sandstone at Trenic in Bohemia.

817 A. TRINKERITE. *G. Tschermak*, J. pr. Cher 1870, xx. 279.

Compact and amorphous. H.=1·5—2. G.=1·025 to chestnut-brown. Transparent to translucent. A wiedzki, Jahrb. Min., 1871, 641:

e; it is especially well charac-
porphyry of Waldböckelheim.

pecies is monoclinic in crystalli-

2. *Notes on a few previously described species.*

198. *Brookite.* A. Schrauf announces that his recent crystallographic studies have proved brookite to be monoclinic and isomorphous with wolframite (Jahrb. Min., 1871, 168).

636. *Caledonite.* Schrauf has found this species to be monoclinic in crystallization. He makes $a \wedge m = 132° 32'$, and $a \wedge c = 90° 30'$, *a*, *m*, *c*, being the planes so lettered in Miller's Mineralogy, and corresponding, *a* to *i-ī*, *m* to *I*, and *c* to *O*, in this work. (Jahrb. Min., 1871, 374.)

Ephesite, see Lesleyite below.

24. *Diamond*. P. v. Jeremejew has discovered minute crystals of diamonds irregularly distributed through plates of xanthophyllite from the Sehischimakian Mountains near Slatoust. They are readily recognized when magnified 30 diameters, and with 200 diameters their crystalline form is seen to be that of the hexa-tetrahedron $3\text{-}\frac{3}{2}$ combined with the tetrahedron, the first four being distinctly convex, while the tetrahedral plane is flat (like fig. 59 p. 21, except that there are also small flat tetrahedral planes). Most of the crystals are colorless. They are symmetrically disposed in their matrix, their trigonal intermediate axes being vertical to the foliation of the xanthophyllite. The green plates of this mineral, nearest the rounded masses of the talcose slate and serpentine enclose unusually large numbers of them and they are likewise found in the two rocks themselves. Jahrb. Min., 1871, p. 275 in Am. J. Sci., III. iii. 57.

Lesleyite. The mineral named lesleyite by I. Lea (see p. 800) has been analyzed by S. P. Sharples (Am. J. Sci., II. xlvii. 319) and J. L. Smith (ib. xlviii. 254). Sharples examined two varieties, one white (anal. 1), and the other red (anal. 3). Smith analysed the white mineral (anal. 2).

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1 white,	33·59	55·41	tr	——	tr	7·43	4·30=100·73
2 "	31·18	55·00	——	0·45	1·20	7·28	4·80=99.91
3 red,	47·00	33·27	2·84	——	——	9·97	6·71=99.79

The analysis of the red variety was made under Sharples's direction by C. W. Roepper. It is an entirely different substance from the white mineral, and was properly referred to pinite by Sharples.

Smith compares the composition of the white variety with that of his ephesite (see Min., p. 507) of which he gives the following new analysis.

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
Ephesite	30·70	55·67	2·55	5·52	1·10	4·91=100.45

There is also a very close correspondence in the physical as well as in the chemical characters of the two minerals, and they are evidently closely related. Lesleyite is found associated with diaspore and both minerals have a peculiarity in regard to their hardness that suggests a want of homogeneity. They are easily scratched with a knife, but they both contain particles which scratch topaz. Under the magnifier they both present glistening scales which are soft and apparently micaceous. It is evident that the minerals are mixtures of corundum and probably diaspore with a mica similar to the damourite found at the lesleyite locality; and that the foliated soft mineral is damourite or a hydrous mica near that species.

Pattersonite. This substance, classed temporarily under the mica group in the supplement to this mineralogy (p. 801), has been analyzed by S P. Sharples with the following results (Am. J. Sci, II. xlvii. 309).

$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Fe}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$ $\dot{\mathrm{Li}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
30·20	14·88	20·55	1·28	tr	11·35	11·73=89.99

The potash is stated to have been determined by the difference (loss), but the analysis foots up, exclusive of the potash, only 78·64 leaving 21·36 for potash instead of 11·35. This large error runs through the calculated oxygen ratios, and hence is not typographical. In view of it, the analysis leads to no satisfactory conclusion. The percentages of silica, iron alumina and water are very near those of prochlorite.

463. *Selwynite.* Ulrich now regards this species as belonging to the *pinite* group (Contrib. Min. Victoria, p. 24).

98. *Sylvanite.* Schrauf's recent crystallographic researches makes this species orthorhombic in crystallization. He says that he has observed the twins described by Kokscharof; and that the angles and planes are given rightly by Miller; and that he has observed 17 new planes. (Jahrb. Min., 1871, 894.)

Tridymite. This new variety of silicic acid, discovered by v. Rath (p. 805, this Min.) in Mexican porphyry, has been found in many localities in Europe; it is especially well characterized in the trachyte of Drachenfels and in the orthoclase-porphyry of Waldböckelheim.

610. *Wolframite.* Des Cloizeaux has shown that this species is monoclinic in crystallization. C. R. lxix. 868.

1890.

Entered according to Act of Congress, in the year 1875,
BY J. D. DANA,
In the Office of the Librarian of Congress, at Washington.

PREFATORY NOTE.

THIS Second Appendix to Dana's Mineralogy, prepared with the co-operation of the author, is designed to make the work complete up to January, 1875.

It includes descriptions of all species announced as new within the past seven years, with the exception of those contained in Appendix I., prepared by Prof. Brush. The names of the latter are, however, also included, with such new facts in regard to them as have been brought out since 1872.

In addition, references are given under the name of each species to all important articles relating to it that have appeared since the publication of the Mineralogy early in 1868. On account of the limited space and time at command, the work, in this latter respect, is, however, little more than an index, yet the attempt has been made to indicate so far as possible the character of each article—*i. e.*, whether it contains a description of crystals (*cryst.*), or an analysis (*anal.*), or a discussion of the chemical composition (*comp.*). Whenever new facts of special importance have been made known in regard to any species, this is noted at somewhat greater length.

An alphabetical arrangement has been adopted for convenience of reference. A list of the more important of recent mineralogical works is added, and also the titles of some memoirs which, owing to their general character, seemed to require a special mention.

For the explanation of *abbreviations*, see Dana's Min., pp. xxxv.-xlv. The black-faced figures, prefixed to names of new species, are intended to indicate their position as arranged in the classification adopted in the Mineralogy: it is not to be understood that these species are necessarily varieties of those near which they are thus made to stand.

LIST OF NEW SPECIES

1. *Native Elements.*

Kongsbergite	32		

2. *Sulphids, Arsenids, etc.*

Arite	4	Horbachite	28
Arsenotellurite	5	Livingstonite	35
Chalcopyrrhotite	11	Luzonite (Enargite)	35
Famatinite	20	Oldhamite	42
Frenzelite	22	Schirmerite	50
Guadalcazarite	25	Spathiopyrite	52
Henryite	27	Valleriite	58

3. *Chlorids, etc.*

Bordosite	8	Erythrosiderite	19
Chlorocalcite	11	Tocornalite	56

4. *Oxyds.*

Asmanite	5	Hydrocuprite	28
Delafossite (Melaconite)	16	Magnochromite (Chromite)	36
Heterogenite	27	Meymacite	38
Hydrargyrite	8		

5. *Anhydrous Silicates.*

Agricolite	1	Microsommite	39
Ardennite (Dewalquite)	4	Trautwinite	56
Manganophyllite	37	Tschermakite	57
Maskelynite	37	Victorite (Enstatite)	18

6. *Hydrous Silicates.*

Allophite	2	Limbachite	34
Chalcomorphite	11	Maconite	36
Cossaite (Paragonite)	68	Nefdieffite	41
Culsageeite (near Jefferisite)	30	Rauite	47
Dudleyite	17	Resanite	48
Foresite	22	Seebachite (Herschelite)	50
Garnierite	23	Sterlingite (Damourite)	15
Grochauite	25	Strigovite	53
Hallite	26	Vaalite	58
Hygrophilite	29	Willcoxite	61
Kerrite	31	Zöblitzite	64

7. *Tantalates, Columbates.*

Koppite	32	Nohlite (near Samarskite)	41

8 *Phosphates, Arsenates, etc.*

Hebronite	27	Stibioferrite	53
Kjerulfine	31	Uranospinite	58
Korarfveite (near Monazite)	32	Veszelyite	59
Miriquidite	40	Wapplerite	60
Rhagite	48	Winklerite	61
Rivotite	48	Zeunerite	63

9. *Borates.*

Ludwigite	35	Priceite	45

10. *Tungstates, Vanadates, etc.*

Cuprotungstite	14	Uranosphærite	57

11. *Sulphates, etc.*

Bartholomite	6	Hydrocyanite	29
Cupromagnesite	14	Maxite (Leadhillite)	38
Dolerophanite	17	Nitroglauberite	41
Ettringite	19	Syngenite (Kaluszite)	54
Guanovulite	64		

12. *Carbonates.*

Dawsonite	16	Schröckeringite	50

13. *Carbo-hydrogen Compounds.*

Aragotite	4	Siegburgite	51
Bombiccite	8	Wheelerite	60
Byerite	9		

The following list includes additional names recently introduced into the science. They belong in part to previously described species, and in part to species which, in consequence of imperfect descriptions, cannot be definitely classified.

Aerugite, Arsenstibite, Bieirosite, Cacheutaite, Campbellite, Carbonyttrine, Cerbolite, Chalcomiclite, Chalypite, Clarite, Corkite, Cryoconite, Cuproapatite, Cuprovanadite, Dauberite, Dernbachite, Ferrotungsten, Glancespar, Glasbachite, Köhlerite, Mariposite, Milanite, Meerschaluminite, Pealite, Plumbocuprite, Plumbiodite, Pyrichrolite, Pyritolamprite, Rhodite, Scacchite, Simlaite, Tapalpite, Wachenrodite, Xanthiosite, Zirlite, Zonochlorite.

For some other new names not belonging to definite mineral species, see *crystallites*, p. 14, *microlites*, p. 39.

APPENDIX II.

AARITE. See ARITE.

ACANTHITE, Min. p. 51.—Localities in Saxony, Frenzel, Min. Lex. Sachsen, p. 2.

ACHTARAGDITE, Min. p. 478.—Description of crystals and analysis, *Hermann*, J. pr. Ch. civ., 104, 182, 1868. Description, Kokscharow, Min. Russl., v., 324.

ACMITE and AEGIRITE, Min. p. 223, 224.—Relation to pyroxene, *Tschermak*, Tsch. Min. Mitth., 1871, 33.

ACTINOLITE, Min. p. 232.—Brewster, N. Y., analysis, *Breidenbaugh*, Am. J. Sci., III., vi., 211, 1873.

ADAMITE, Min. p. 565.—Cap Garonne, analysis and description, *Damour*, C. R., lxvii., 1124; Pisani, C. R. l. 1001, 1870.

AERUGITE. Adam, Tableau Min., 1869, p. 43. A doubtful arsenate of nickel ($\dot{\mathrm{N}}\mathrm{i}^{8}\ \ddot{\bar{\mathrm{A}}}\mathrm{s}$) from Johanngeorgenstadt, analyzed by Bergemann (Dana Min. p. 548).

AESCHYNITE, Min. p. 522,—anal.: *Marignac*, Ann. Ch. Phys., IV., xiii., 5, 1868; *Hermann*, J. pr. Ch. cv., 105, 321; *Rammelsberg*, Pogg., cl., 214, 1873.

AGALMATOLITE, Min. p. 480.—China, Kenngott, Jahrb. Min. 1870, 782.

336 A. **Agricolite.** *Frenzel*, Jahrb. Min., 1873, 791, 947; 1874, 686; *Breithaupt* (references in Dana's Min., p. 391).
Monoclinic (Groth). C = 110°. In globular or semi-globular forms, with radiated or fibrous structure. Also in indistinct groups of crystals. Soft, heavy, brittle. Color hair-brown (Schneeberg)· colorless to wine-yellow (Johanngeorgenstadt). Lustre adamantine, greasy.

Composition same as for eulytite (q.v.) 2 $\bar{\mathrm{B}}\mathrm{i}$, 3 $\ddot{\mathrm{S}}\mathrm{i}$. Analysis, Frenzel, l. c.

$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\mathrm{B}}\mathrm{i}$	$\bar{\mathrm{F}}\mathrm{e}$		
16·67	81·82	0·90	=	99·39

Occurs at Johanngeorgenstadt on quarz, associated with bismuth, cloanthite, bismite; also at the mine Neuglück, Schneeberg.
The *arsenwismuth* of Breithaupt has until now been included with eulytite, but the investigations of Frenzel and Groth show that, though having the same composition, it is different in crystalline form, and hence is a distinct species.

ALBERTITE, Min. p. 753.—Probable origin, *S. F. Peckham*, Am. J. Sci. II., xlviii., 362, 1869.

ALBITE, Min. p. 348.—Saas, cryst., *F. Scharff*, Jahrb. Min., 1869, 342.
St. Gotthard, cryst., *Hessenberg*, Min. Not. ix., 40, 1870.
Media, Penn., anal., *Leeds*, Am. J. Sci., III., vi., 25, 1873.
Crystallographic memoir, with full list of planes, *Brezina*, Tsch. Min. Mitth., 1873, 19.
Crystallographic memoir, twinning laws, etc., *v. Rath*, Pogg. Ann. Erg., Bd. v., 425, 1870.

See also Feldspar.

ALLANITE, Min. p. 285.—Schmiedefeld, Thüringer Wald (Schwarze Krux), cryst., many new forms, *Bauer*, Würtemberg. Nat. Jahresheft, 1872, 246.
Vesuvius (orthite), cryst., *v. Rath*, Pogg., cxxxviii., 492.
Finland (Erbo and Kyokslätt), Wiik, Œfv. Finsk. Vet. Soc., Helsingfors, xiii., 75, 1870-71.
Composition discussed, *Rammelsberg*, ZS. G. Ges., xxiv., 60, 1872.
Greenland, Fredrickshaab, anal., *Rammelsberg*, ZS. G. Ges., xxiv., 60, 1872.
Found in the Böhmer Wald, near Husinec, Krejci, Ber. Böhm. Ges., 1873, p. 360.
Amherst Co., Va., anal., *J. A. Cabell*, Ch. News, 1874, p. 141.

ALLOPHANE, Min. p. 419.—Dehrn (near Limburg), Nassau, anal., *v. Rath*, Pogg., cxliv., 393, 1871.
Northampton, England, *Hermann*, Q. J. G. Soc., xxvii., 234, 1871.

448 A. Allophite, *Websky*, ZS. G. Ges., xxv., 399, 1873.
In dense, micro-crystalline masses, on fracture dull, and easily polished to a greasy lustre by the hand. H. less than calcite. G. = 2·641 (Leffler). Color, pale grayish-green. In appearance very similar to pseudophite; distinguished from serpentine by its inferior hardness.

Analysis Leffler (l. c.).

$\ddot{\text{Si}}$	$\dddot{\bar{\text{Al}}}$	$\dddot{\bar{\text{Fe}}}$	$\dddot{\bar{\text{Cr}}}$	$\dot{\text{Mg}}$	$\dot{\text{H}}$	
36·23	21·92	2·18	0·85	35·53	2·97	= 99·68

Neglecting the water Leffler gives the formula 2 ($\dddot{\bar{\text{Al}}}\ \ddot{\text{Si}}$) + 3 ($3\dot{\text{Mg}}\ \ddot{\text{Si}}$). If the water be reckoned in the oxygen ration for $\dot{\text{R}} : \dddot{\bar{\text{R}}} : \ddot{\text{Si}} : \dot{\text{H}} = 5 : 4 : 6\frac{2}{3} : 1$; or for all bases (including $\dot{\text{H}}$) to silica = 3 : 2. The water goes off only at a high temperature.
Occurs at Langenbielau, Silesia; also at Reichenstein. From a quarry of limestone occurring in the gneiss.

ALTAITE, Min. p. 44.—Red Cloud Mine, Colorado, anal., *Genth*, Am. Phil. Soc., Philad., xiv., 225, 1874.

Waltsch, Bohemia, altered to hyalite, *Boricky*, Ber. Böhm. Ges., 1873, 65.

795 A. **Aragotite.**—*Durand*, Proc. Acad., Cal., iv., p. 218, 1872, (Am. J. Sci., III., vol. vi., 67).

A volatile hydrocarbon related to idrialite. It occurs at the New Almaden Mine, Cal., in bright yellow scales, impregnating a crystalline siliceous dolomite; also on cinnabar at the Redington Mine.

It contains no arsenic, nor sulphur, nor any metal. Insoluble in oil of turpentine, alcohol, and ether.

ARCANITE, Min. p. 615.—See **APHTHITALITE**.

284 A. **Ardennite.**—*Lasaulx* and *Bettendorf*, Ber. Nied. Ges. Bonn, xxix., p. 189, Nov. 24, 1872; Pogg. cxlix., 241, 1873. DEWALQUITE, Pisani, C. R., lxxv., 1542, Dec. 2, 1872; lxxvii., 329, 1873.

Orthorhombic. a (vert.)$=0{\cdot}3135$, $b=1$, c (brach.) $0{\cdot}4663$. Observed planes $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, I, $i\text{-}\frac{3}{2}$, $i\text{-}\breve{2}$, $1\text{-}\breve{i}\,.\,1\,.\,1\text{-}\frac{3}{2}$. $I \wedge I$ (over $i\text{-}\breve{i}$)$=130°\ 0'$, $i\text{-}\frac{3}{2} \wedge i\text{-}\frac{3}{2}=145°\ 28'$, $i\text{-}\breve{2} \wedge i\text{-}\breve{2}=94°\ 0'$. $1 \wedge 1=150°\ 50'$ and 114° 40′. $1\text{-}\breve{i} \wedge 1\text{-}\breve{i}=112°\ 12'$ (Pisani 112° 24 $a' \wedge a'$). Above determinations by v. Rath.

Good crystals very rare, mostly in fragments without terminations. Habit much like ilvaite; $1\text{-}\bar{i} \wedge 1\text{-}\bar{i}=112°\ 40'$ for ilvaite, $=112°\ 12'$ for ardennite. Prismatic planes strongly striated. Cleavage, $i\text{-}\breve{i}$ perfect, I very distinct.

Pisani gives the following optical determinations. Acute bisectrix, positive, normal to the cleavage plane $i\text{-}\breve{i}$ (in which the optic axes are observed). Angle of axes in air: red rays=68° 58′, yellow = 66° 37′, green, 62° 18′ (mean). Des Cloizeaux found: red = 76° 7′–79° 9′, yellow 72° 55′, 74° 26′, green 68° 36′-70° 59′.

H. 6–7. G. = 3·620. Color yellow to yellowish-brown; in thin splinters translucent, red. Dichroic. Brittle and fragile.

Analyses 1, 2, 3, 4, Lasaulx and Bettendorf, Pogg., cxlix., 243, 245. 5. Pisani, C. R., lxxv. 542. 6. same, ib., lxxvii., 329.

	$\ddot{\text{Si}}$	$\dddot{\overline{\text{Al}}}$	$\dddot{\overline{\text{Mn}}}$	$\dot{\text{Mn}}$	$\dddot{\overline{\text{Fe}}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\text{V}}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\text{As}}}$	Cu ·	ign.

5.	28·70	28·36	——	26·40	2·94	4·30	4·32	1·80	——	1·30	0·98	= 99·10
6.	28·40	24·80	——	25·70	1·31	2·98	4·07	3·12	6.35	0·22	5·20	= 102·15

In analyses 1 and 2, L. & B. found 2 p. c. Pt., Pd., etc., which, as they afterward showed, came from platinum dishes used in the analysis, the water was overlooked. Analyses 3 and 4 were made subsequently, and by an improved method. The manganese is present in the form $\dot{\text{Mn}}$, as is shown by Pisani (not $\dddot{\overline{\text{Mn}}}$ as in analyses 1 and 2 of L. & B.).

B. B.—Easily fusible to a black glass. With borax gives a manganese bead. The water can only be driven off at a strong red heat.

According to Pisani the arsenic is readily recognized on heating the mineral in a matrass, mixed with carbonate of soda and cyanid of potassium, a ring of metallic arsenic being obtained. He explains the high percentage of vanadic acid obtained by Lasaulx on the ground that he has overlooked the arsenic.

Found near Ottrez (Salm Chateau) in the Ardennes, Belgium, with quartz (containing particles of pyrolusite) and albite.

Lasaulx first noticed this mineral under the name of *mangandisthen*, in consequence of a supposed resemblance to cyanite. This, as Pisani urges, is on several accounts an objectionable name, and is naturally superseded by the name *ardennite*, which too has the right of priority over *dewalquite*.

ARGENTITE, Min. p. 678.—Cryst., new forms, *Schrauf*, Ber. Ak. Wien, lxiii., 165, 1871.

ARGENTOPYRITE, Min. p. 39.—Cryst. memoir, *Schrauf*, Ber. Ak. Wien, lxiv., 192, 1871.

72 A. **Arite.** The arsenid of nickel, containing 27·8 p. c. antimony, described by Berthier from the Basses-Pyrénées (Dana, Min. p. 60), has been called aarite (more properly *arite*, Pisani) by Adam, Tableau Min., 1869, p. 40.

The same mineral has been subsequently investigated by Pisani (C. R., lxxvi., 239, 1873), and he concludes that it is merely a variety of breithauptite. An analysis gave him: As 11·5, Sb 48·6, Ni 37·3, Zn 2·4 = 101·5, corresponding to an arseniferous breithauptite. G. = 7·19. It is similar to the mineral from Allemont also described by Berthier (Dana Min. p. 60, anal. 4), which is an antimoniferous niccolite.

The name arite, however, may still be well retained for the antimonarsennickel of Petersen (Pogg., cxxxvii., 396, 1869), the analysis of which agrees very closely with that of Berthier for the Pyrenees mineral. The mineral described by Petersen occurs massive at the Wenzel mine, Wolfach, Baden, in a coarse granular limestone. It is sometimes accompanied by wolfachite. An analysis afforded: As 30·06, Sb 28·22, Ni 39·81, Co tr, Fe 0·96, S 1.77 = 100·82. H. = 5·5, G. = 7·50. B.B. fuses with a strong reaction for arsenic and antimony. With soda gives a magnetic globule.

Arsenic (native), Min. p. 17.—Found in the argentiferous mines of San Augustin, State of Hildago, Mexico (H. = 2, G. = 7·24), La Naturaleza, xl., p. 313, 1873.
Marienberg, Saxony (arsenglanz), *Frenzel*, Jahrb. Min., 1873, 25; 1874, 677.

See also Danaite.

33 A. **Arsenotellurite**, a name proposed by *Hannay* for a supposed new tellurid. It occurs in small brownish scales upon arsenical iron-pyrites. An analysis gave him (on ·6347 gr.) Te = 40·71, As = 23·61, S = 35·81, corresponding to the formula 2 TeS_2, As_2S_3. *No locality mentioned.* J. Ch. Soc., II., xi., p. 989, 1873.

Arsenstibite. Adam, Tableau Min., 1869, p. 42.—A hydrous arsenate of antimony, for which Pisani gives the formulas $\ddot{S}b^3\,\overset{\cdot\cdot\cdot}{\ddot{A}}s + 15\dot{H}$ and $\ddot{S}b^5\,\overset{\cdot\cdot\cdot}{\ddot{A}}s + 30\dot{H}$.

Asbestus, Min. p. 234.—Found at Pelham, Mass., *Adams*, Am. J. Sci., II., xlix., 271, 1870

Asbolite, Min. p. 181.—Saalfeld, note, *v. Kobell*, Ber. Ak. München, 1870, 49.

231 B. **Asmanite**, *Maskelyne*, Phil. Trans., clxi., p. 361, 1871 (v. Rath, Pogg., Erg. Bd. vi, 382, 1873.

Orthorhombic. Occurring planes *O*. *I*. *i*-*ĭ*, ⅓-*ĭ*, 1-*ĭ*, ⅔-*ĭ*, ½-*ĭ*, ¼-*ĭ*, ⅔, ½, ⅓. *a* (vert.) : *b* : *c* = 3·31320 : 1·0000 : 1·7437. *I* ∧ *I* 120° 20′. *O* ∧ 1-*ĭ* = 117° 46′. *O* ∧ ½ : 117° 39′.

Cleavage *O* good, surface having a vitreous lustre, *I* difficult. Lustre generally resinous, resembling that of opal. Extremely brittle, especially in outer portions.

H. = 5·5. G. = 2·245. Optically bi-axial, divergence large, in air = 107°–107½° (approximately), being somewhat greater for red rays than blue. First bisectrix normal to *i*-*ĭ* (100), second normal to *O*. Double-refraction, positive.

Composition nearly pure silica, consequently the same as for quartz and tridymite. Analysis, Maskelyne, l. c. 1. On 0.3114 gr. 2. On 0·2653 gr.

	$\ddot{S}i$	$\dot{F}e$	$\dot{C}a$	$\dot{M}g$	
1.	97·43	1·12	0·58	1·51	= 100·64
2.	(99.21)	0·79 etc.			100·00

Found in the meteoric iron of Breitenbach, in very minute grains, generally much rounded and stained with iron on the surface.

It is mixed with bronzite (after the removal of the iron, troilite and chromite), and constitutes about one-third of the mixed siliceous minerals. Maskelyne suggests that the rounded character of the mineral and of the accompanying bronzite may be due to this having undergone superficial fusion, or having been softened by the intense heat generated by the rapid course of the meteorite in the air; an idea which, he says, seems to be supported by the brittleness of the outer portions of the grains.

Aspidolite, *v Kobell*, Ber. Ak. München. March, 1869. Appendix I., p. 2.
Found in gneiss near Snarum, Moravia, Tsch. Min. Mitth., 1871, 112.

Stassfurt (simonyite, q. v., Appendix I., p. 14), *v. Rath*, Pogg., cxliv., 586 1871.

805 A. **Bombiccite**, *Bechi*, *Achiardi*, Min. Toscana, p. 358, 1873; *Bombicci*, Mem. Ac. Sc Bologna, II., ix., 1869; *Guareschi*, Boll. Com. Geol. Ital., 1871, 70.

Triclinic. $I \wedge i\text{-}\bar{i} = 174° 50'$, $1 \wedge i\text{-}\bar{i} = 159°$.
H. = 0·5–1. G. = 1·06. Transparent. Colorless.
Analysis, Bechi (after deducting impurities) l.c.

H	O	C
10·70	14·74	74·56 = 100·00

This corresponds to the formula $H^{12}OC^7$.
Softens with heat, and fuses at 75°, and at a higher temperature it volatilises. Insoluble in water, but extremely soluble in sulphid of carbon; also soluble in ether and in alcohol.
Found in lignite at Castelnuovo d'Avane, in the upper valley of the Arno, Tuscany.
Achiardi refers to this species a fossil resin, described by Guareschi (l.c.) as found in the upper valley of the Arno. It occurs in irregular whitish-yellow masses, soft. It fuses easily, and burns with a smoky flame. Two analyses gave:

	H	O	C
1.	9·41	17·87	72·72 = 100·00
2.	9·12	13·94	76·94 = 100·00

These analyses lead to a formula essentially identical with that given for bombiccite.

BORACITE, Min. p. 595.—Stassfurt, crystallized, *Schultze*, Jahrb. Min., 1871, 844.
Cryst. note, *Schrauf*, Tsch. Min. Mitth., 1872, 114.

BORATES.—Found in Nova Scotia, *How*, Phil. Mag., IV., xli., 274, 1871.
Peru, analyses (with wide variations probably due to admixtures of $Ca Cl_2$ and $Ca SO_4$), *Walker*, Ch. News, xviii., 203, 1868; see also *Thierceliu*, Bull. Soc. Ch., xvii., 387, 1872.

BORAX, Min. p. 597.—Sierra Nevada, *Silliman*, Am. J. Sci., III., vi., 130, 1873; see also Jahrb. Min., 1874, 716.

144 A. **Bordosite**.—Ann. des Mines, VII., i., p. 412, 1872. Bertrand describes a mineral substance. color yellow to red, occurring with an amalgam rich in Hg and Ag, and resulting from its decomposition. It becomes dark rapidly on exposure to the air.

Analysis.	$AgCl$	Hg^2Cl	HgO
	31·23	45·53	22·70 = 99·46

Bertrand regards the HgO as adventitious, and proposes for it the name HYDRARGYRITE, deducting this there remain AgCl 40·69, and Hg_2Cl 59·31 = 100, or $AgCl + Hg_2Cl$, to which he gives the name of BORDOSITE. Both species appear very uncertain. Locality Los Bordos in Chili.

BORNITE, Min. p. 44.—From the Ardennes, anal., *Koninck*, Bull. Acad. Belg., II., xxvii., 290, 1871.

BOULANGERITE, Min. p. 99.—Silbersand, near Mayen, anal., *v. Rath*, Pogg., cxxxvi., 430. (Var. Embrithrite), composition, *Frenzel*, J. pr. Ch., II., ii., 360.

BOURNONITE, Min. p. 96.—Liskeard, Cornwall, anal., *Wait*, Ch. News, xxviii., 752, 1873

BOUSSINGAULTITE, Min. p. 635.—Bechi gave the name boussingaultite (C. R., lviii., 583, 1864) to the double salt of ammonia and magnesia occurring at the boracic acid fumaroles of Tuscany. The same mineral has since been fully described by Popp (Ann. Ch. Pharm., Suppl. Bd., viii., 1, 1870), and has received from him the name *cerbolite*. It seldom occurs quite pure in nature, but on re-crystallization it is obtained in perfect crystals of monoclinic form. An analysis of material thus obtained gave: [illegible], NH^4 9·38, $\dot{Mg}$ 11·05, $2\bar{\bar{S}}$ 44·39, $7\dot{H}$ 35·16 = 99 98, which affords the formula $NH_4O\bar{\bar{S}} + \dot{Mg}\,\bar{\bar{S}} + 6\dot{H}$. A number of analyses of the natural salt showed that $\dot{Fe}$, $\dot{Mn}$ and $\dot{Ca}$ may, in variable proportions, replace the $\dot{Mg}$

830 F. **Byerite.**—A name given by Mallet (Am. J. Sci., III., ix., 146, 1875) to the mineral coal of Middle Park, Colorado. It belongs to the class caking-bituminous, and gave on analysis, 39·95 p.c. volatile matter (gas and tarry oil), 54·03 p.c. fixed residue (coke and ash), and 6·02 p.c. water. G. = 1.323. Color jet-black. Powder brown. It resembles albertite in the large amount of gas and tarry oil yielded by it, but differs in being heavier and in yielding no soluble products with bisulphide of carbon, ether, etc. It also resembles torbanite, but is heavier, does not crackle in the fire, and melts and intumesces when heated.

CHALCOMICLITE. A name used by Blomstrand for a mineral having the composition $3CuS, FeS^3$, and hence synonymous with bornite (see Rammelsberg Min. Chem., p. 115). Œfv. Ak. Stockholm, xxvii., p. 24, 1870.

370 A. Chalcomorphite, v. Rath, Pogg. Ann., Erg. Bd. vi., p. 376, 1873.
Hexagonal, *a* (vert.) = 1·8993. Occurring planes *O*, *I*, 1. *O* : 1 = 114° 24′. Cleavage, *O* distinct. H. = 5. G. = 2·54. Lustre vitreous. Pyr., gives water in a matrass, becoming white and lustreless. B.B., fuses with difficulty on the edges, curling up like skolecite. Soluble in HCl with the separation of gelatinous silica.

Analysis (l. c.) on 0·26 gr.	$\ddot{Si}$	$\ddot{\bar{Al}}$	$\dot{Ca}$	$\dot{H}$ (and some $\ddot{C}$)
	25·4	4·0	44·7	16·4

loss, in part $\dot{Na}$, 9·5 = 100·00.
From the Laacher See, also from Niedermendig in the Eifel. Occurring in cavities in limestone-inclosures in the lava.

CHALCOPHYLLITE, Min. p. 571.—Cornwall, analyses, *Church*, J. Ch. Soc., II., viii., 168, 1870.

CHALCOPYRITE, Min. p. 65.—Cryst. memoir, *A. Sadebeck*, ZS. G. Ges., xx., 595, 1868; even apparently holohedral forms are really hemihedral, same, ib., xxiv., 185, 1872.
Tuscany, analyses, Boll. Com. Geol. Ital., 1873, 239.

68 A. Chalcopyrrhotite, Blomstrand, Œfv. Akad. Stockholm, xxvii., p. 23, 1870.
Massive. Color like that of pyrite with a tinge of brown. Hardness nearest that of chalcopyrite. G. = 4·28.
Analysis (l. c.)

	Fe	Cu	S	residue
⅔	48·22	12·98	38·16	0·74 = 100·09

which gives the formula Fe^4CuS^6 or $\left.\begin{matrix}2FeS\\CuS\end{matrix}\right\}Fe\,S^3$
Occurs at Nya Kopparberg, Sweden, in small imbedded portions with magnetite, spalerite, calcite, as well as chondrodite, the mineral most characteristic of the locality.

Chalypite. A name given by Shepard to a compound of iron and carbon found by Forchhammer as a leading constituent of the Niakornak iron. The carbon varied from 7·23 – 11.06 p. c., corresponding to the formula CFe^2 (Am. J. Sci., II., xlviii., 28, 1867). Meunier uses the name (Ann. Ch. Phys., IV., xvii., 36, 1869), and introduces another, **Campbellite,** for a similar compound, C. = 1·50 p. c., seemingly contained in the Campbell Co., Tenn., meteoric iron, which was analyzed by J. L. Smith (Am. J. Sci., II., xix., 159, 1855).

Pseudomorph after barite, *Durand*, Cal. Acad. Sci., iv., 211, 1872.

Clarite. Sandberger has given this name to a supposed new mineral occurring at the Clara mine, near Schapbach, Kinzigthal. The chief constituents were found to be sulphur, antimony, arsenic and copper. Color dark steel-gray. Apparently orthorhombic, with cleavage perfect in one (macrodiagonal) direction. Occurs altered to chalcopyrite; also affords covellite as a result of decomposition. In addition to these minerals, tetrahedrite has been found at the same mine, and in larger quantities barite, fluorite, psilomelane and limonite. Jahrb. Min., 1874, 960.

CLAUSTHALITE, Min. 42, 798.—Mendoza, *Domeyko*, 2d App. Min. Chili, p. 30, 1867; 4th App., p. 21, 1874. *Stelzner*, Tsch. Min. Mitth., 1873, 254.

COERULEOLACTITE, *Petersen*, Jahrb. Min., 1871, 353—Appendix I., p. 8.
Dr. Genth has observed a similar mineral with wavellite at General Trimble's iron mine, near White Horse Station, Chester Valley R. R., Chester Co., Penn (the locality erroneously called "Steamboat"). It is in cryptocrystalline, botryoidal, incrustations of a pale greenish blue or sky-blue color. An analysis of nearly pure material gave him: $\ddot{\mathrm{P}}$ 36·31, $\ddot{\bar{\mathrm{A}}}\mathrm{l}$ 38·27, $\dot{\mathrm{C}}\mathrm{u}$ 4·25, $\dot{\mathrm{H}} = 21{\cdot}70$, quartz $0{\cdot}54 = 101{\cdot}07$. G. = 2·696. Neither the wavellite nor any other associated mineral contains copper, so that Dr. Genth regards it as probably belonging to the constitution of the mineral (priv. contrib.).

Cryoconite. Kryokonit, *Nordenskiöld*, Œfv. Ak. Stockholm, 1871, 293; 1874, 3. (Pogg., Ann., cli., 161, 1874; Geol. Mag., ix., 355, 1872.)
Nordenskiöld has given the name cryoconite to the powder found by him in Greenland covering the surface of land ice, as also at a distance of 30 miles from the coast. It formed a layer of gray powder, sometimes several millimetres in thickness, and often agglomerated into small round balls of loose consistency. Under the microscope it was seen to consist for

the most part of colorless, crystalline, angular grains; there were also some organic particles some transparent fragments showing cleavage surfaces (feldspar?), green crystalline fragments (augite?), and black, opaque magnetic particles. An analysis gave *G. Lindström* (l. c.)

$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mn}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{Na}}$	$\ddot{\mathrm{P}}$	Cl
62·25	14·93	0·74	4·64	0·07	5·09	3·00	2·02	4·01	0·11	0·06

water, organic matter (ignited at 100°) = 2·86, hygroscopic water 0·34 = 100·12.

Nordenskiöld states that the amount of foreign constituents (named above) is very small, so that *if the transparent grains all belong to the same mineral*, its composition can be deduced from the analysis, the oxygen ratio for $\dot{\mathrm{R}} : \bar{\mathrm{R}} : \ddot{\mathrm{Si}} = 2 : 3 : 14$, and the formula as given by him is $2\dot{\mathrm{R}}\,\ddot{\mathrm{Si}}^2 + \bar{\mathrm{Al}}\ddot{\mathrm{Si}}^3 + \dot{\mathrm{H}}$. Its specific gravity was 2·63 (21° C.), hardness inconsiderable, and crystalline form monoclinic. The magnetic particles contain metallic iron, with cobalt and probably nickel. In regard to the source of the powder, the conclusion arrived at is that it must either have come from Jan Mayen, or from some unknown volcanic region in the interior of Greenland, or else it must be of *cosmical origin*.

The oxygen ratio given is a very unlikely one, and there seems to be no sufficient ground for considering the material essentially homogeneous, as claimed by Nordenskiöld. The composition is very closely that of an oligoclase-trachyte, so that the cryoconite may be properly, as he calls it, a "trachytic dust."

CRYPTOMORPHITE, Min. p. 599.—Extensive deposits in Nevada, Am. J. Sci., III., iv., 146. —See Priceite.

Crystallites. A name given by Vogelsang to the forms, often observed especially in igneous rocks, which show a regular arrangement or grouping, but have not the properties of crystals, particularly not their regular exterior form. They seem to form an intermediate step between amorphous matter and true crystals. See Vogelsang,—DIE KRYSTALLITEN, Bonn, 1875, this App. p. vi. To the crystallites, Vogelsang has given a variety of names according to their form or appearance: *Globulites* (Vogelsang, p. 13), *margarites* (p. 19), *longulites* (p. 21, 112), *sphärolites* (p. 131), *cumulites* (p. 134), *globosphärites* (p. 134), *belonosphärites* (p. 135), *felsosphärites* (p. 135), *granosphärites* (p. 135). See also *Ferrite*, *Opacite*, *Viridite*.

CUBANITE, Min. p. 65.—Found at Tunaberg, Kafveltorp, Sweden, analyses, *Cleve*, Geol. För. Förh. Stockholm, I., 105, 1873.

Culsageeite. See JEFFERISITE.

CUPRITE, Min. p. 133.—Liskeard, Cornwall, cryst. (¾-½ new), *Schrauf*, Tsch. Min. Mitth., 1871, 106.

CUPROAPATITE. Adam, Tableau, Min., 1869, p. 45. An apatite from Chili, containing 20·93 p. c. $\dot{\mathrm{Cu}}$; analyzed by Field (Dana Min., p. 532.)

669 A. Cupromagnesite. *Scacchi*, Rend. R. Accad. Sc. Napoli, Oct., 1872 (ZS. G. Ges., xxiv., 506). Found at Vesuvius as a product of the eruption of April, 1872, in bluish-green crusts, consisting of copper vitriol and sulphate of magnesia. From the solution crystals are obtained having the composition $(\dot{\mathrm{Cu}}\ \dot{\mathrm{Mg}})\ \dddot{\mathrm{S}} + 7\ \dot{\mathrm{H}}$, and isomorphous with iron vitriol.

CYANITE, Min. p. 375.—No. Carolina, with corundum, *Genth*, Proc. Am. Phil. Soc. Philad., xiii., 381, 1873.

CYANOCHALCITE, *Hermann*, J. pr. Ch., cvi., 65.—Appendix I., p. 4.

CYANOTRICHITE, Min. p. 666.—Cap Garonne, note by Pisani, C. R., lxx., 1004, 1870.

CYMATOLITE, Min. p. 455.—Optical characters, *Bauer*, ZS. G. Ges., xxvi., 186, 1874.

CUPROSCHEELITE, Min. p. 606.—Chili, analyses, Domeyko, 2d Append. Min. Chili, p. 8 1867.

615 A. Cuprotungstite. Tungstate de cuivre, *Domeyko*, Ann. des Mines, VI., xvi., p. 387, 1869. Cuprotungstite, *Adam*, Tableau Min., 1869, p. 82.

Amorphous, forming crusts of one or two mm. thickness, enveloping small, hard, glittering kernels of cupreous scheelite (the latter green in color).

Color yellowish-green. Streak bright greenish-yellow. Analyses of fragments taken with a knife from different crusts.

	$\dddot{\mathrm{W}}$	$\dot{\mathrm{Cu}}$	$\dddot{\bar{\mathrm{F}}\mathrm{e}}$	$\dot{\mathrm{Ca}}$	residue ($\ddot{\mathrm{Si}}$)	$\dot{\mathrm{H}}$
1.	55·7	——	4·2	2·1	2·4	4·5
2.	56·48	30·63	2·53	2·00	3·87	4·62=100·13
3.	55·54	28·15	3·62	1·00	6·00	4·62= 99·03

Analysis (2) was made on what was regarded as the purest material. Part of the iron probably belongs with the residue ($\ddot{\mathrm{Si}}$). The composition is expressed by the formula $\dddot{\mathrm{W}}^2\dot{\mathrm{Cu}}$, there being also some $\dddot{\mathrm{W}}^3\mathrm{Ca}$ present.

On charcoal blackens, and fuses easily to a black globule, slightly porous, and with an uneven surface. In the closed tube gives water, at a red heat loses 4½ p. c. Easily decomposed by nitric acid, even in the cold, giving a yellow residue soluble in ammonia, and a solution strongly colored by copper.

Found near the copper mines of Llannico in the environs of Santiago, Chili. The cuproscheelite (Dana Min. p. 606) associated with the cuprotungstite had sometimes a rich dark green color, also a clear green color with a tint of yellow; lustre vitreous or resinous, with an imperfect lamellar structure. H.=4. An analysis gave:

$\dddot{\mathrm{W}}$	$\dddot{\bar{\mathrm{F}}\mathrm{e}}$	$\dot{\mathrm{Cu}}$	$\dot{\mathrm{Ca}}$	ign	insol.
(76·00)	1·55	5·10	15·25	1·70	0·40=100

The ordinary scheelite also occurs at the same locality, but is easily distinguished by its superior hardness.

CUPROVANADITE. Adam, Tableau Min., 1869, p. 33. Syn. of chileite, 1853, Dana Min., p. 612.

DAMOURITE, Min. p. 487.—Horrsjöberget, anal., *Igelström*, Œfv. Ak. Stockh., xxv., 37, 1868.

As a result of decomposition, anal., *Tschermak*, Ber. Ak. Wien, lviii., 16, 1868.

Salm Chateau, anal., *Koninck* and *Davreux*, Bull. Acad. Roy. Belg., II., xxxiii., 324, 1872.

Optical character, *Bauer*, ZS. G. Ges., xxvi., 183.

No. Carolina, associated with corundum, analyses, *Genth*, Am. Phil. Soc. Philad., xiii., 384, 1873.

A variety of damourite has been called STERLINGITE by *J. P. Cooke* (Mem. Am. Ac. Boston, 1874, p. 39).

It agrees with *damourite* in physical properties, but differs in the value of the optic-axial angle. Biaxial divergence about 70° (damourite 10°-12°), plane of axes parallel to the shorter diagonal. Dispersion small. Analysis by C. E. Munroe. (l. c.)

$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{A}}\mathrm{l}}$	$\dddot{\bar{\mathrm{F}}\mathrm{e}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
43·87	36·45	3·36	10·86	5·19

Regarding the water as basic with the protoxides, the atomic ratio becomes $\ddot{\mathrm{Si}} : \dot{\mathrm{R}} : \dddot{\bar{\mathrm{R}}} = 4 : 3 : 1$ (as in damourite).

Found at Sterling, Mass., associated with spodumene in the vein of a large bowlder rock. (This same name was given by Alger to the zincite of New Jersey.)

DANAITE (arsenopyrite), Min. p. 78.—Relation to glaucodot, *Tschermak*, Ber. Ak. Wien, lv., 447, 1867.

San Jose, anal., Domeyko 2d App. Min. Chili, p. 13, 1867.

Shown to possess positive and negative thermo-electrical varieties, *Schrauf* and *Dana*, Ber. Ak. Wien, lxix, 152, 1874.

DATOLITE, Min. p. 380.—Isomorphous with euclase and gadolinite, *Rammelsberg*, ZS. G. Ges., xxi., 807. See Euclase.

Andreasberg, anal., *Lemberg*, ZS. G. Ges., xxiv., p. 250, 1872.

Bergen Hill, cryst. monograph, new forms, *E. S. Dana*, Am. J. Sci., III., iv., 16, 1872.

Arendal, Toggiana, etc., cryst., enumeration of all known planes, with the addition of some new ones, *E. S. Dana*, Tsch. Min. Mitth., 1874, 1.

Santa Clara, Cal., associated with garnet and idocrase, *J. L. Smith*, Am. J. Sci., III., viii 434, 1874.

DAUBERITE, Adam, Tableau Min., 1869, p. 64. Synonym of zippeite, Haidinger, Handb 1845. Dana Min., p. 667.

Dawsonite, *B. J. Harrington*, Can. Nat., vol. vii., p. 305, 1874.
Monoclinic with $C = 105°$? In thin bladed crystals, sometimes somewhat fibrous. Double refracting. H. = 3. G. = 2·40. Lustre vitreous. Color white. Transparent to translucent.
Analysis (l. c.) Harrington.

	$\dddot{\bar{\text{A}}}\text{l}$	$\dot{\text{M}}\text{g}$	$\dot{\text{C}}\text{a}$	$\dot{\text{N}}\text{a}$	$\dot{\text{K}}$	$\dot{\text{H}}$	$\ddot{\text{C}}$	$\ddot{\text{S}}\text{i}$	
1.	32·84	tr	5·95	20·20	0·38	11·91	29·38	0·40	= 101·66
2.	32·68 ($\dddot{\bar{\text{F}}}\text{e}$ tr)	0·45	5·65	$\underbrace{\quad 20{\cdot}17 \quad}$		[10·32]	30·72		= 100·00

The two analyses, made at different times, show considerable constancy of composition, and seem to point to "a hydrous carbonate of alumina, lime and soda, or perhaps a compound consisting of a hydrate of alumina combined with carbonates of lime and soda."
There is approximately the quantity of water required to form a di-hydrate of alumina, and nearly enough carbonic acid to form a neutral carbonate of lime and bicarbonate of soda. If it be a carbonate of alumina, it gives the mineral peculiar interest as being a compound, not surely identified hitherto either in nature (see hovite, Dana Min., p. 709), nor in the laboratory.

DECHENITE, Min. p. 609.—Cryst., *Schrauf*, Ber. Ak. Wien, lxiii., 167, 1871.

178 A. Delafossite, *C. Friedel*, C. R., lxxvii., p. 211, 1873.
In small crystalline plates, cleavable into thin opaque lamellæ. H. = 2·5, G. = 5·07. Color dark gray like graphite, with a more decided metallic lustre. Streak blackish-gray.
An analysis gave Friedel (l. c.)

$\dot{\bar{\text{C}}}\text{u}$	$\dddot{\bar{\text{F}}}\text{e}$	$\dddot{\bar{\text{A}}}\text{l}$
47·45	47·99	3·52 = 98.96

This corresponds to $\dddot{\bar{\text{F}}}\text{e}, \dot{\bar{\text{C}}}\text{u}$, (but is it not a mixture ?)
B.B. Fusible with difficulty, coloring the flame green. Easily soluble in HCl, even in the cold.
Found on yellowish-white lithomarge from the region of Katharinenburg, Siberia, perhaps also from Bohemia. Named for the mineralogist Delafosse.

DELESSITE, Min. p. 497.—Filling cavities in an amygdaloid, Nova Scotia, anal., *How*, Phil. Mag., IV., xxxvii., 269.

DIAMOND, Min. p. 21.—Occurrence described, *Kokscharow*, Min. Russl., V., 373: VI., 190 et seq.
Found at Dlaschkovitz, Bohemia, *Schafarik*, Pogg., cxxxix., 188, 1870; ibid., cxl., 336; *Zepharovich* throws doubt upon the matter, ibid., cxl., 652.

Views on the origin of, W. B. Clarke, Ch. News, xxiv., 16, 40, 64, 78.
Probably exists with the platinum of Oregon, *Wæhler*, Am. J. Sci., II., xlviii., 441.
Probable existence in the gold washings of California, with zircons and topaz, *Silliman*, Am. J. Sci., III., v., 384; found at Cherokee, Butte Co., Cal., same, ib., vi., 133, 1873.
Behavior on heating, Rose, Pogg., cxlviii., 497; v. Schrötter, Ber. Ak. Wien, lxiii., 462, 1871; Baumhauer, Vers. Need. Ak. Amsterdam, II., vii., 200, 1873.
A uniaxial crystal, Schrauf, Tsch. Min. Mitth., 1873, 289.
Knop has shown that the supposed diamonds of Jeremejew do not exist in the xantophyllite (Jahrb. Min., 1871, 275; Appendix I., p. 19). On the contrary, the appearances are due, not to inclosed crystals, but to cavities which, says Knop, owe their existence to the corroding influence of acids either in nature or in the laboratory (Jahrb. Min., 1872, 785).

DIAPHORITE, *Zepharovich*, Ber. Ak. Wien, lxiii., 130; Appendix I., p. 4.

DIASPORE, Min. p. 168.—Chester Co., Penn., anal., *Sharples*, Am. J. Sci., II., xlvii., 319, 1868.

Chester, Mass., containing phosphoric acid, *Shepard*, Am. J. Sci., II., l., 96, 1870.
No. Carolina, occurrence described, *Genth*, Am. Phil. Soc. Philad., xiii., 372, 1873.

DIMORPHITE (Scacchi), Min. p. 28.—*Kenngott* suggests that both types of this species are to be referred to orpiment (auripigment), Jahrb. Min., 1870, 587.

DIOPSIDE, Min. p. 214.—From the chrysolite bombs of the Eifel, *Rammelsberg*, Pogg., cxli., 516.
Relation to minerals of the pyroxene group, *Tschermak*, Tsch. Min. Mitth., 1871, 21.

DIOPTASE, Min. p. 248.—Composition, *Rammelsberg*, ZS. G. Ges., xx., 536, 1868.

DOLOMITE, Min. p. 681.—Brewster, N. Y., altered to serpentine; to brucite; pseudomorph after chondrodite, *J. D. Dana*, Am. J. Sci., III., viii., 375, 1874.
Pseudomorph after garnet, *Laube*, Lotos, xxii., 209, 1872.
Analyses, *Lemberg*, ZS. G. Ges., xxiv., 218 et seq., 1872.

DOMEYKITE, Min. p. 36.—Analyses, *Frenzel*, Jahrb. Min., 1873, 26.
Zwickau, Weisbach, Jahrb. Min., 1873, 64.

634 B. Dolerophanite, *Scacchi*, Note Mineralogiche, p. 22, Napoli, 1873. Extract from Atti Acad. Sci. Napoli, v. (read 1870).

Monoclinic. Observed planes, *i-ī*, *i-ĭ*, *O*; $-\frac{1}{3}$-*ĭ*, $\frac{1}{3}$-*ĭ*, $\frac{2}{3}$-*ĭ*, 1-*ĭ*, $\frac{3}{2}$-*ĭ*; 1, -3; $\frac{3}{2}$-$\frac{3}{2}$; $-\frac{4}{3}$-$\frac{4}{3}$, -5-$\frac{5}{4}$, $\frac{1}{2}$-3̆, 1-3̆; $-\frac{7}{9}$-$\frac{7}{3}$. C = 113° 52′. *a* (vert.) : *b* : *c* = 0·9962 : 1 : 0·6753. *i-ī* ∧ 1 = 70° 3′, *i-ĭ* ∧ 1 = 141° 5′, *O* ∧ 1 = 110° 9′. Crystals small, rarely having a diameter of more than two millimetres. Well polished. Opaque. Color brown. Powder brownish-yellow.

Composition $\mathrm{Cu_2\ddot{S}}$. Analyses:

	$\dot{\mathrm{Cu}}$	$\dddot{\mathrm{S}}$	insoluble	loss
1.	62·27	36·07	1·22	0·44 = 100.
2.	65·20	33·49	$\overbrace{1·31}$	= 100.

A little $\dot{\mathrm{Cu}}\dddot{\mathrm{S}}$ accompanying the dolerophanite is probably the occasion of the excess of $\dddot{\mathrm{S}}$.

Kept for some time in water, the crystals dissolve in part, giving a blue solution; they preserve their form, however, though the color changes from brown to bluish. Dissolves easily in nitric acid. B.B., fuses, leaving a black scoriaceous residue. Unaltered at a temperature of 260°. With the fluxes gives reaction for copper.

Found by Scacchi at Vesuvius, having been produced by sublimation during the eruption of October, 1868. The name is derived δολερός, fallacious, φαίνω, to appear.

See also Hydrocyanite.

459 A. Dudleyite, Genth, Am. Phil. Soc. Philad., xiii., p. 404, 1873.

Has the form of margarite, from the alteration of which it has been made. Color soft bronze, or brownish-yellow; lustre, pearly.

Analysis (l. c.)

$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dddot{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Li}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	ign
32·42	28·42	4·99	1·72	16·87	0·19	1·52	0·56	13·43 = 100·12

Oxygen ratio $\dot{R} : \ddot{\bar{R}} : \ddot{Si} : \dot{H} = 6 : 12 : 14 : 10$ nearly, or $2(3\dot{R}, 2\ddot{Si}) + 4(\ddot{\bar{R}}, 3\ddot{Si}) + 10\dot{H}$.

Exfoliates slightly on heating, and fuses with difficulty to a brownish-yellow blebby mass. Easily decomposed by hydrochloric acid with separation of silica in scales. Found at the Cullakenee Mine, Clay Co., N. Carolina, and in larger quantity with margarite at Dudleyville, Alabama.

Brewster, N. Y., analysis, Breidenbaugh, Am. J. Sci., III., vi., 211, 1873; altered to serpentine, *J. D. Dana*, ibid., viii., 375, 1874.

See also *Bronzite*.

234 A. Victorite, *Meunier*, Ber. Ak. Wien, lxi., p. 26, 1870.

Occurs in needle-like crystals in cavities in the meteoric iron from Cordillere, Deesa, Chili. Crystals 0·3 mm. in length and 0·07 in width, appearing under the microscope as six-sided prisms with four-sided pyramids; they are grouped together in a rosette. Examined crystallographically by Des Cloizeaux, as follows:

$I \wedge i\text{-}\breve{\imath}$ $(g'm) = 134°\ 8'–20'$; $i\text{-}\bar{\imath} \wedge i\text{-}\breve{\imath}$ $(gh') = 90°\ 40'$; $(g'm) = 46°$; $I \wedge i\text{-}\bar{\imath}$ $(mh') = 137°\ 20'$; $I \wedge I$ $(mm') = 93°–93°\ 40'$; $I \wedge i\text{-}\bar{\imath}$ $(h'm) = 136°\ 25'–135°\ 40'$; $I \wedge i\text{-}\breve{\imath}$ $(g'm) = 134°, 134°\ 40'$; $I \wedge I$ (over $i\text{-}\breve{\imath}$) $(mm) = 88°\ 40'$. In polarized light shows bright colors. Fracture conchoidal, no cleavage observed. Colorless (showing absence of iron). B.B. infusible, not attacked by acids. Meunier considers the victorite as a variety of enstatite entirely free from iron.

Eosite, *Schrauf*, Ber. Ak. Wien.—Appendix I., p. 5.

Epiboulangerite, *Websky*, ZS. G. Ges., 1869, 747.—Appendix I., p. 5.

Epidote, Min. p. 281.—Cryst. memoir, homomorphous with azurite, *Schrauf*, Ber. Ak. Wien, lxiv., 159, 1871.

Striegau, cryst. description (new forms), *E. Becker*, Koksch. Min. Russl., V., 366.

Composition discussed, Kenngott, Jahrb. Min., 1871, 449.

Untersulzbach, cryst. description, *Brezina*, Tsch. Min. Mitth., 1871, 49; *C. Klein*, Jahrb. Min., 1872, 113, 132; optical properties determined with great precision, *Klein*, ibid., 1874, 1; analyses, *Rammelsberg*, ZS. G. Ges., xxiv., 69; xxiv., 649; *Ludwig*, ibid., xxiv., 465 (Tsch. Min. Mitth., 1872, 187); *v. Drasche*, Jahrb. Min., 1872, 120; *v. Kottal*, Ber. Ak. Wien, lxvi., 200, 1872: see also Jahrb. Min., 1873, 422.

The analyses of Ludwig (l. c.) show the presence of about 2 p. c. of water as an essential constituent of epidote. In this Rammelsberg finally coincides (l. c.). According to the former the composition is expressed by the formula $Si_6\,Al_6\,Ca_4\,H_2\,O_{26}$ (earlier obtained by Tschermak, and Kenngott); this gives the oxgyen ratio for $\dot{H}$, $\dot{R}$, $\overset{\cdots}{\overline{R}}$, $\ddot{Si}=1:4:9:12$.

Epigenite.—Appendix I., p. 5.

Epiphanite, Igelström, Œfv. Ak. Stockh., 1868, 29.—Appendix I., 6.

Epistilbite, Min. p. 443.—Glatz, Silesia, cryst. *Rammelsberg*, ZS. G. Ges., xxi., 95; *Websky*, ibid., xxi., 100, 1869.

Lünddsdörrsfjall, Sweden, anal. (result somewhat doubtful, possibly a new mineral), *Igelström*, Jahrb. Min., 1871, 361.

Ersbyite, Min. p. 361.—Pargas, analyses, *v. Rath* concludes that this mineral should be placed in the scapolite group, Pogg., cxliv., 384; Wiik, Œfv. Finsk. Vet. Soc., xiii., 79, 1870–71. See also *Wiik*, Œfv. Finsk. Vet. Soc., xiv., 26, 1871–72.

Erythrite, Min. p. 558.—Wittichen, Baden, anal., *Petersen*, Pogg., cxxxiv., 86.

143 A. Erythrosiderite, *Scacchi*, Rend. R. Acc. Sci. Napoli, Oct., 1872 (ZS. G. Ges., xxiv., 505). Orthorhombic, with two zones affording angles 110° and 92°. Color red. Very soluble. Composition expressed by the formula $2KaCl+Fe_2\,Cl_3+2\dot{H}$. Found at Vesuvius imbedded in the lava of April, 1872, and undoubtedly formed by sublimation at that time.

Related to Kremersite.

Esmarkite, Des Cloizeaux has shown that there are two minerals, from the same locality, which have borne this name. One is a true praseolite (fahlunite, Dana, Min., p. 485), the other in crystalline form, and in composition, approaches very near to anorthite, Ann. Ch. Phys., IV., xix., 176, 1870.

683 A. Ettringite, *Lehmann*, Jahrb. Min., 1874, 273.

Hexagonal. a (vert.)$=0{\cdot}9434$. Occurring planes O, I, 1, $\frac{1}{2}$. $I\wedge 1=137°\,27'$, $1\wedge\frac{1}{2}=162°\,14'$. In minute needle-like prismatic crystals, seldom more than 3 mm. in length, thickness $\frac{1}{10}$ to $\frac{1}{2}$ mm. Cleavage prismatic perfect. H.=about 2. G.=1·7504. In appearance very similar to chalcomorphite.

Analysis, Lehmann, l. c. (on 0·3623 gr.).

$\overset{\cdots}{\overline{Al}}$	$\dot{Ca}$	$\dddot{S}$	$\dot{H}$	loss (probably $\dddot{S}$)		
7·76	27·27	16·64	45·82	2·51	=	100·00

Lehmann gives the formula $\overset{\cdots}{\overline{Al}},\ 3\dddot{S}+6\,(\dot{Ca}\,\dot{H})+26$ aq.

Occurs in cavities in the limestone-inclosures in lava of the Bellenberg at Ettringen and Mayen, in the district of Laach.

Euclase, Min. p. 379.—Isomorphous with datolite and gadolinite, Rammelsberg, ZS. G. Ges., xxi., 807, 1869.

The isomorphism of datolite and euclase was proved by J. D. Dana in 1854 (Am. J. Sci., II., xvii., 215): moreover the similarity in chemical composition (exhibited by Rammelsberg) was brought out in Dana's Mineralogy, 1868, pp. 362, 363 (Am. J. Sci., II., xlix., 400, 1870). The statement in Groth, Tabellar. Uebersicht der Min., 1874, 91, is consequently to be corrected.

Nova Scotia, *How*, Phil. Mag., IV., xxxvii., 270.

132 B. Famatinite, *Stelzner*, Tsch. Min. Mitth., 1873, p. 242.
Massive, sometimes reniform. Fracture uneven, somewhat brittle. H. = 3·5. G. = 4·57. Color mixture of copper-red and gray. Streak black.
Composition $4(3Cu_2S, Sb_2S_3) + 3(Cu_2S, As_2S_5)$, or an antimonial enargite (see luzonite). Analyses 1, 2, Siewert, l. c.; 1, from the Mejicana Upulunzos mine; 2, from the Mejicana Verdiona mine.

		S	Sb	As	Cu	Fe	Zn	Gangue	
1.	[illegible]	29·17	21·23	4·07	44·12	0·82	0·59	——	= 100·00
2.	½	29·63	20·54	3·63	45·34	0·51	0·59	0·63	= 100·87

Pyr. In the closed tube decrepitates, giving off sulphur readily, and on stronger heating also some sulphid of antimony. On charcoal gives off white fumes of antimony, leaving a black, brittle metallic globule. Occurs with enargite, chalcopyrite, pyrite, etc., in the Famatina Mts., Argentine Republic.
It has also been found by Hübner at Cerro de Pasco, Peru (Frenzel, Jahrb. Min., 1874, 685; Tsch. Min. Mitth., 1874, 279).

Des Cloizeaux has recently investigated the optical properties of the triclinic feldspars (C. R., lxxx., Feb. 8, 1875). The principal results obtained by him are contained in the following table, in which *Bx* stands for *bisectrix:*

	ALBITE.	OLIGOCLASE.	LABRADORITE	ANORTHITE
Acute bisectrix	always +	generally — sometimes +	always +	always —
Angle made by the + Bx. with a normal to *i-ĭ* (*g*)	15°	18° 10′	30° 40′	Position of the Bx. has no simple relation to the planes observed on the crystals.
Same, with a normal to *O* (*p*)	78° 35′	68°	56°	
Angle made by the line in which the plane of the optic-axes cuts *i-ĭ*, with edge *i-ĭ* / *O*(*g*′/*p*)	20°	Line parallel to the edge *O*/*i-ĭ*.	27°–28°	
Same, with edge *i-ĭ*/*I*(*g*′/*m*)	96° 28′ (front)	" "	37° 23′–36° 25′	
Ordinary dispersion	$\rho < v$(+ Bx.)	$\rho < v$(+ Bx.)	$\rho > v$(+ Bx.)	$\rho < v$(— Bx.)
Dispersion parallel or perpendicular to plane of polarization	*Inclined;* probably also slight *horizontal.*	*Crossed;* also slight *inclined.*	*Crossed;* also slight *inclined.*	*Inclined.*
Appar'nt optic-axial angle (in air)				
—— for red rays	80° 39′	89° 35′	88° 15′	84° 58′
—— for blue rays	81° 59′	88° 31′	87° 48′	85° 59′
	(Roc tourné)	(Sunstone. Tvedestrand)	(Labrador)	(Somma)

The axial divergence is quite constant for albite, labradorite and anorthite, but varies for oligoclase even in different sections taken from the same specimen. Des Cloizeaux concludes from his observations that labradorite and oligoclase have an equal right with albite and anorthite to be considered independent species, contrary to the views presented by Tschermak. Andesite he concludes to be altered oligoclase, while tschermakite (q. v.) is identical with albite.

392 A. Foresite, *v. Rath*, Pogg., clii., p. 31, 1874. Cookeite, *Achiardi*, Min. Toscana II., p. 236; Boll. Com. Geol. d'Italia, 1874, 306.

Orthorhombic. In crystalline crusts on tourmaline, or lining cavities. Crystals very minute, prismatic in habit, with planes *i*-*ī*, *i*-*ĭ*, *O* and 1. Angles obtained (approximate) $O \wedge 1 = 132°$, $i\text{-}\bar{i} \wedge 1 = 121°$. Form resembling stilbite, with which it seems to be isomorphous. Cleavage parallel to *i*-*ĭ*, distinct; lustre on this face, pearly. G. = 2·405. Color white.

Analysis 1. v. Rath, l. c. 2. Bechi, Min. Tosc., II., 236. 3. Pullè and Capacci, Boll. Com. Geol. Ital., 1874, 311.

	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dot{\mathrm{Mn}}$.	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{Ka}}$	$\dddot{\mathrm{Be}}$	$\dot{\mathrm{H}}$
1. $\frac{2}{3}$	49·96	27·40	——	5.47	0·40	1·38	0.77	——	15.07 = 100.45
2.	44·60	36·00	1·02	5·50	0·02	2·33	0·72	0·71	9·18 = 100·08
3.	44·60	38·00	1·02	5·50	0·20	3·33	0·72	0·71	6.00 = 100·08

For his analysis v. Rath deduces the formula $\dot{\mathrm{Na}}_2$, $3\dot{\mathrm{Ca}}\ 8\dddot{\mathrm{Al}}\ 24\ddot{\mathrm{Si}}\ 24\dot{\mathrm{H}}$. Oxygen ratio for $\dot{\mathrm{R}} : \dddot{\mathrm{R}} : \ddot{\mathrm{Si}} : \dot{\mathrm{H}} = 1 : 6 : 12 : 6$ (stilbite $= 1 : 3 : 12 : 6$).

B. B. Expands and melts. With difficulty decomposed by HCl, even after ignition. The water goes off in part at 100°–110° C., after continued heating at 200° the mineral loses 5–5½ p. c., and to drive off the whole amount present (15·06 p. c. and 15.09 in two trials) a strong red heat was required.

Found at San Piero in Campo, Island of Elba, in cavities in the granite, with tourmaline, lepidolite, quartz, feldspar. It occurs, as a secondary product, along with heulandite and stilbite, covering these minerals.

A mineral from the same locality, with the foresite of v. Rath, associated in the same way, and similar in physical properties (anal. 2), was referred provisionally by Achiardi (l. c.) to cookeite (cuocheite), although with a question as to the propriety of so doing. It is like cookeite (*Brush*, Dana's Min., 1868, p. 489) in manner of occurrence, but, as mentioned by Achiardi, has a very different chemical composition. (Could a confounding of the relative amounts of $\ddot{\mathrm{Si}}$ and $\dddot{\mathrm{Al}}$ have suggested the identity of the Elba mineral with cookeite, viz.: $\ddot{\mathrm{Si}}$ 35, $\dddot{\mathrm{Al}}$ 45 (cookeite), $\ddot{\mathrm{Si}}$ 45, $\dddot{\mathrm{Al}}$ 36 (foresite). Pullè and Capacci first suggested that the species was new in an article entitled 'Un Viaggio nell' Arcipelago Toscano,' published in a Florence newspaper (1874).

FRANKLINITE, Min p. 152.—Found at Centerville, near Paterson, N. J., Am. J. Sci., II., xlviii., 138, 1869. [This observation was erroneous, Brush.]

Pseudomorph after calcite, *Leeds*, Am. Chemist, iv., 4, Oct., 1873.

FREIESLEBENITE. See DIAPHORITE.

30 A. Frenzelite.—Selenwismuthglanz, *Castillo*, Naturaleza II., 174, 1873, Jahrb. Min., 1874, 225; *Frenzel*, Jahrb. Min., 1874, p. 679. Frenzelite, *Dana*.

Massive, structure fine-granular, foliated to fibrous. Orthorhombic? In minute, needle-like crystals, irregular, strongly striated vertically. Crystals sometimes single imbedded in galapektite, sometimes grown together, forming semi-compact masses. Cleavage distinct parallel to *i*-*ĭ*.

H. = 2 (Castillo), 2·5–3 (Frenzel). G. = 5·15 (Castillo), 6·25 (Frenzel). Color bluish-gray. Streak, gray, grayish black shining. Lustre metallic. Soft, malleable.

Analysis, Frenzel l. c.

Se	Bi	S		
24·13	67·38	6·60	=	98·11

This corresponds to the formula $\mathrm{Bi_2\,Se_3}$, where some of the Se is replaced by S, or more strictly $2\mathrm{Bi_2\,Se_3} + \mathrm{Bi_2S_3}$. A partial examination on a very small quantity gave Rammelsberg Bi = 65·4, Se = 16·7. He suggests the presence of Zn, which is not confirmed by Frenzel B. B. fuses on charcoal with a blue flame, giving a strong odor of selenium. With iodid of potassium gives a fine red coating, even without the addition of sulphur, thus proving that it is already present. Decomposed by aqua regia on slow heating.

Found at Guanajuato, Mexico.

Frenzel has given the first complete description of this species, in fact he speaks of having been aware of its existence for some years, so that it may well receive his name.

416 A. **Garnierite**, *Garnier*, Bull. Soc. G., II., xxiv., p. 448 (1867), *A. Liversidge*, J. Chem. Soc., II., xii., 613, July, 1874.
Amorphous, enclosed between thin plates of silica, which has filled fissures in the original material. H.=2·5. G.=2·27.
Color bright apple-green. Streak pale green. Touch not unctuous. Adheres to the tongue.
Analysis (l. c.) Liversidge.

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}\dddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Ni}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{H}}$		
$\frac{2}{2}$	47·24	1·67	24·01	21·66	tr	5·27	=	99·85

Liversidge suggests the formula $(\dot{\mathrm{Mg}}\dot{\mathrm{Ni}})_{10}\ \ddot{\mathrm{Si}}_{8}+8\dot{\mathrm{H}}$.
In the closed tube gives off water, becoming gray; with borax gives a nickel bead. On immersion in water breaks to pieces with a sharp crackling sound, the fragments having a conchoidal fracture.
Occurs in veins traversing a serpentine rock near Noumea, capital of New Caledonia; associated with chromic iron and steatite.
Liversidge calls attention to the relation of this species to alipite, and suggests at the same time that it is probably a result of decomposition and consequently hardly deserves a new name, proposing, however, in case it prove to exist in large quantities, the name from the locality (*i.e.*, *noumeaite*). A private contribution from Mr. W. B. Clarke (from whom Mr. Liversidge obtained his specimen) states that the mineral was discovered by Garnier in 1865, and should properly receive the name *garnierite*, especially as it was found at Mont d'Or, before the town of Noumea existed. In the Bull. Soc. G., II., xxiv., 448 (1867), Garnier in an article on New Caledonia mentions the occurrence of a hydrous magnesian silicate (=gymnite) in the veins of the serpentine, and adds that it is sometimes colored green through the presence of a silicate of nickel (*i. e.*, the so-called garnierite?). It is hence probably a mixture. If an analysis of the similar material by Leibius (Sydney Herald, Sept. 23, 1874) is correct ($\ddot{\mathrm{Si}}$ 48·90, $\dot{\mathrm{Mg}}$ 10·93, $\dot{\mathrm{Ni}}$ 6·46, $\dddot{\mathrm{S}}$ 0·83, $\dddot{\bar{\mathrm{Fe}}}+\dddot{\bar{\mathrm{Al}}}$=15·18, $\dot{\mathrm{H}}$=17·75), it would imply an entire want of constancy of composition.

GENTHITE, Min. p. 471.—Webster, No. Carolina, anal., *Dunnington*, Ch. News, xxv. 370, 1872.

GEYSERITE. PEALITE is a name given by Dr. Endlich to a variety of geyserite (opal) from the silicious deposits of the Upper Geyser basin of Firehole river. An analysis gave him $\ddot{\text{Si}}$ = 95·84, $\overset{\dots}{\overline{\text{Al}}}$ tr, $\overset{\dots}{\overline{\text{Fe}}}$ 2·68, $\dot{\text{Mg}}$, $\dot{\text{Ca}}$, $\dot{\text{Na}}$, $\dot{\text{Li}}$, tr., ign 1·50=100·02. The specimen had a milk-white color, crypto-crystalline structure, semi-vitreous aspect. G. = 2·49. Another kind was greenish-brown to greenish-white in color; amorphous; lustre vitreous. G.=2·0816 It contained 6·3 p. c. water. (Hayden's U. S. Geol. Survey, 6th Ann. Rep.) Am. J. Sci. III., vi., 66.

GERSDORFFITE, Min. p. 72.—Lempälä, Finland, *Wiik*, Oefv. Finsk. Vet. Soc., xiii., 75, 1870–71.

GIESECKITE, Min. p. 479.—Occurrence, with other minerals, in Brittany, *de Limur*, Bull. Soc. G., III., i., 166, 1874.

429 A. GILBERTITE, Min. p. 798.—Frenzel has investigated the hitherto doubtful gilbertite, and concludes that it is really a good species belonging to mica group. It occurs at the various tin mines of the Erzgebirge (Saxony and Bohemia), Zinnwald, Ehrenfriedensdorf, etc.

Frenzel mentions two varieties: The first (*a*) is of a greenish to yellowish-white color; translucent. H. = 1: G. = 2·65–2·72. It occurs massive, with a dense to crystalline structure, filling all the cavities between the cassiterite and wolframite. The second variety (*b*) occurs in spherical or stellate forms, and also in groups of six-sided tabular crystals. It is, moreover, found pseudomorph after scheelite and apatite. H. = 3. G. =2·82. According to Fischer the mineral shows itself under the microscope to be homogeneous. Analyses 1. and 2. of variety *a*; 1. from Ehrenfriedensdorf, 2. from Pobersbau. 3. variety *b*, from Ehrenfriedensdorf.

	$\ddot{\text{Si}}$	$\overset{\dots}{\overline{\text{Al}}}$	$\dot{\text{Fe}}$	$\dot{\text{Ca}}$	$\dot{\text{Mg}}$	$\dot{\text{Ka}}$	$\dot{\text{Na}}$	Fl	$\dot{\text{H}}$
1.	48·96	30·96	2·24	0·26	1·97	8·47	1·65	1·04	3·83 = 99·38*
2.	48·10	32·30	3·30	0·40	1·12	10·02	——	0·81	4·09 = 100·14*
3.	48·10	31·55	3·10	1·30	1·33	8·62	2·14	0·88	3·52 = 100·54

* Contains also traces of manganese.

The water is given off only at an elevated temperature. B. B., fuses in fine splinters, coloring the flame slightly red. (Compare analyses of margarodite, Min. p. 310.)

GISMONDITE, Min. p. 418.—Found near Baumgarten, east of Giessen, *Streng*, Jahrb. Min., 1870, 430; cryst. description, same, ibid., 1874, 578.

GLASBACHITE, Adam, Tableau Min., 1869, p. 52.—A doubtful selenid of lead from Glasbach, analyzed by Kersten. See *Zorgite*, Dana Min., p. 43.

Glancespar, Pogg. Ann., cxlvii., p. 272.—Vom Rath has investigated this mineral, first mentioned by v. Dechen in his Geognost. Führer in das Siebengebirge, p. 154, Bonn, 1861. Occurs in small prismatic fragments in the basalt of the Siebengebirge. Form a rhombic prism having an acute angle of 88¼°; cleavage distinct with pearly lustre, angle on prismatic face = 134° 7′ H. between quartz and feldspar. G. = 3·150.

Analysis v. Rath (l. c.) on 0·7 gr.

$\ddot{\text{Si}}$	$\overset{\dots}{\overline{\text{Al}}}$	$\overset{\dots}{\overline{\text{Fe}}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$
36·7	57·9	4·4	0·7	0·8 = 100·5.

Part of the CaO, MgO, and Fe_2O_3 are due to impurities (augite, magnetite), and deducting these we obtain the formula $\overset{\dots}{\overline{\text{Al}}}\ddot{\text{Si}}$, or that of cyanite, from which it differs in prismatic angle and specific gravity. B.B., infusible.

The form given is exactly that of andalusite ($I \wedge I$ = 88° 12′ andalusite, = 88° 15′ glancespar), and the specific gravity is identical, as is the composition also. In cleavage it seems to be somewhat different.

458 B. Grochauite, Websky, ZS. G. Ges., xxv., p. 395, 1873. See also Bock, Inaug. Dissert., Breslau, 1868.
Monoclinic? In small, six-sided, tabular crystals, rough and allowing no measurements, the edges being rounded off by irregular planes. Optically biaxial, angle of axes about 20° to 30°. Double refraction weak, probably positive. Cleavage basal easy, forming thin soft plates.
Analysis, Bock (l. c.).

$\ddot{\mathrm{Si}}$	$\overline{\mathrm{Al}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{H}}$
28·20	24·56	5·27	30·94	12·15 = 101·12.

Oxygen ratio for $\dot{\mathrm{R}} : \overline{\mathrm{R}} : \ddot{\mathrm{Si}} : \dot{\mathrm{H}} = 4 : 3 : 4 : 3$.
Occurs mixed with a chromic spinel (magnochromite, q. v.), also in cavities crystallized, in serpentine at Grochau, south of Frankenstein, in Silesia.

65 B. Guadalcazarite. Schwefelselenquecksilber, *Castillo* and *Burkhart*, Jahrb. Min., 1866, 411. Guadalcazite, *Adam*, Tableau Min., p. 59. Guadalcazarite, *Petersen*, Tschermak's Min. Mitth., 1872, p. 69; *Burkhart*, ibid., 243.
Massive, cryptocrystalline. H. = 2. G. = 7·15. Lustre greasy-metallic. Color deep black. Streak bluish-black to black.
Composition $6HgS + ZnS$, with some of the sulphur replaced by selenium and the zinc by cadmium.
Analysis, Petersen (l. c.)

S	Se	Hg	Zn	Cd	Fe
14·58	1·08	79·73	4·23	tr	tr = 99·62

Pyr. On charcoal first decrepitates, giving off mercurial fumes, and a selenium odor; on continued blowing the white deposit of oxyd of zinc and also a distinct cadmium reaction. In the open tube deposits a sublimate, gray to black, of Hg, S, and Se, giving off sulphurous acid, while the yellowish oxyd of zinc remains behind. Soluble in aqua regia, with the separation of some sulphur. In composition it is not very unlike cinnabar, but quite different in physical properties.

Occurs at Guadalcazar, Mexico, with cinnabar, quartz and barite. This mineral was first mentioned by Castillo and Burkhart (l. c.), but no complete description was given. (Dana Min. p. 109.) According to Castillo it crystallizes in rhombohedrons, also occurs imbedded. Lustre metallic. Color lead-gray, granular. H. = 3. G. = 6·69–7·165. The qualitative examination gave Castillo essentially the same results as those since obtained by Petersen.

GUANO, and guano minerals. See Appendix I., p. 6.

GUARINITE, Min. p. 383.—Shown to be orthorhombic, not tetragonal in cryst. form, *v. Lang*, Tsch. Min. Mitth., 1871, p. 81. The same result was obtained earlier by Guiscardi, see Brezina in Tsch. Min. Mitth., 1874, 285.

Cryst., new forms (⅓-ì, ⅔-ì), *Brezina*, Tsch. Min. Mitth., 1872, 17.

445 C. Hallite, *Leeds*, Journ. Frank. Inst., III., lxii., 70. *J. P. Cooke*, Mem. Am. Ac. Boston, 1874, p. 59.

Hexagonal? Occurs in large rough six-sided prisms with easy micaceous cleavage. Color in some varieties green, in others yellow.

G. (yellow) = 2·402, (green) = 2·398.

Analyses (l. c.) Munroe, 1. green var., 2. yellow.

		$\ddot{\mathrm{S}}\mathrm{i}$	$\bar{\mathrm{A}}\mathrm{l}$	$\bar{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{H}}$
1.	$\frac{3}{1}$	35·89	7·45	8·78	1·18	31·45	0·46	14·33 = 99·49
2.	$\frac{3}{2}$	35·26	7·58	9·68	0·32	31·51	0·61	14·78 = 99·74 (Mn tr)

Oxygen ratio for $\dot{\mathrm{R}} : \bar{\mathrm{R}} : \ddot{\mathrm{S}}\mathrm{i} : \dot{\mathrm{H}} = 2 : 1 : 3 : 2$—the two varieties are identical.

Exfoliates somewhat on heating; decomposed by hydrochloric acid after ignition.

A foreign mineral is interspersed between the leaves of the hallite, in spear-shaped, very narrow forms, and lying in parallel lines, crossing at angles of 60° and 120°, like the magnetite in the Pennsbury mica. The mass of this interspersed mineral was too small to affect the analysis essentially.

Found at East Nottingham, 3 miles south of Oxford, Chester Co., Penn., in nests or pockets in the serpentine formation. Named from Mr. John Hall, of Philadelphia.

This name has been previously used as a synonym of aluminite, Dana Min., p. 658.

503 B. Hebronite, *v. Kobell*, Ber. Ak. München, 1873, 284.

The *montebrasite* of Des Cloizeaux (C. R., lxxiii., 306, 1247) was announced in Appendix I., p. 11, to be identical with amblygonite, the statement being founded upon the results of analyses by Pisani (C. R., lxxiii., 1479) and v. Kobell (Ber. Ak. München, Feb. 3, 1872); it is moreover confirmed by a subsequent analysis by Rammelsberg (Ber. Chem. Ges. Berlin, 1872). Des Cloizeaux, however, has investigated the matter further (C. R., lxxv., 114; lxxvi., 319, 1873). He has found that, while the original montebrasite is identical with amblygonite, the mineral from Hebron, Me., differs from the latter in optical character (amblygonite, Saxony $\rho > \upsilon$; hebronite, Maine, $\upsilon > \rho$), and in having a third cleavage surface inclined upon the other two (making 105 together as in amblygonite) at an angle of 135°-136° and 89°. They differ somewhat moreover in chemical composition (see below). Des Cloizeaux has also identified a mineral agreeing with that from Hebron at Montebras, and upon this ground he proposes to *transfer* the name montebrasite to this. V. Kobell (l. c.), on the other hand, considers such a course as likely to lead to great confusion, and proposes, wisely as it seems, to let the name montebrasite drop entirely, and to call the Hebron mineral, if it be a distinct species, *hebronite*. In this proposal he is supported by Rammelsberg, ZS. G. Ges., xxv., 59, 1873.

Analyses of hebronite: 1. G. = 3·01; 2. G. = 3·029, Pisani, C. R., lxxv., 79, 1872; 3. von Kobell (l. c.), G. = 3·06; 4. amblygonite, Rammelsberg, Ber. Chem. Ges. Berlin, 1872, 78.

	F	Ṗ	Āl	L̇i	Ṅa	Ḣ		
1. Hebron,	5·22	46·65	36·00	9·75	——	4·20	= 101·82	Pisani.
2. Montebras,	3·80	47·15	36·90	9·84	——	4·75	= 102·44	Pisani.
3. Auburn, Me.,	5·50	49·00	37·00	7·37	1·06	4·50	= 103·43	v. Kobell.
4. Penig,	9·44	48·00	36·26	6·68	3·29	K̇ 0·43	= 104·10	Ramm.

As will be seen by comparison with analysis 4. of normal amblygonite, the hebronite differs in containing less fluorine and soda, while it has about 4 p. c. of water. The true nature of the mineral, even if it be a good species, cannot be regarded as satisfactorily settled, as Rammelsberg remarks.

HELVETAN, Min. p. 801.—Simmlar has obtained for helvetan the following analysis: S̈i 67·07, Āl 13·05, F̄e 4·43, Ca 2·38, Ṁg 2·18, K̇ 7·37, Ṅa 1·69, Ḣ 1·85 = 100·02. He calls it a feldspar with the habit of a mica, Jahrb. Min., 1868, 348.

HERSCHELITE, Min. p. 437.—Victoria, anal. and description of crystals, *Ulrich*, Contrib. Min. Victoria, p. 26, 1870. See Seebachite.

218. Heterogenite, *Frenzel*, Journ. für prakt. Ch., II., v., p. 404, 1872.

Amorphous, massive in globular, reniform masses, with little lustre. H. 3. G. 3·44. Color black, blackish to reddish-brown; streak dark-brown.

Analysis (after deduction of foreign constituents, Cu, Bi, etc.).

C̈o	O	Ḣ		
72	5·98	21·28	=	99·21

Composition $\dot{C}o\ 2\dddot{\overline{C}}o+6\dot{H}$, it being a product of the decomposition of smaltite (Speiskobalt).

Pyr. In matrass gives water. B. B. fuses with difficulty on the edges, coloring the flame green; after ignition it is weak magnetic. Gives a cobalt reaction with the fluxes. Soluble in dilute hydrochloric acid, with evolution of chlorine, leaving a residue.

Occurs sparsely with calcite and pharmacolite in cobalt and nickel veins at Schneeberg.

HEULANDITE, Min. p. 444.—Composition discussed, *Rammelsberg*, ZS. G. Ges., xxi., 93, 1868.

Cornwall, analyses (differing somewhat from previous results), *Church*, J. Ch. Soc., II., viii., 3.

81 A. Horbachite, *Knop*, Jahrb. Min., 1873, 523. In crystalline masses, showing an imperfect cleavage direction with a brighter metallic lustre than on the ordinary fracture surfaces. H. 4·5. G. 4·43. Color resembling pyrrhotite but darker, pinchbeck-brown to steel-gray. Streak black.

Analysis on pure material (as proved by the microscope), 1. Wagner (l. c.), 2. Rammelsberg (G.=4·7), Pogg., cxxi., p. 361.

		S	Fe	Ni		
1.	¼	45·87	41·96	11·98	=	99·81
2.		40·03	55·96	3·86	=	99·85

Analysis 1. gives $Fe_8Ni_2S_{15}$ or $4\overline{Fe}S_3+\overline{Ni}S_3$. It is claimed by Knop to be the first discovery of a sesquisulphid in nature, though the analysis by Rammelsberg shows that there is a very considerable variation in composition.

Decomposed rather easily under the influence of air and water, forming iron and nickel vitriol. Occurs with chalcopyrite in irregular masses in the serpentinized gneiss at Horbach in the Black Forest.

HYDRARGYRITE. See BORDOSITE.

Hydrocuprite. Genth has given the name hydrocuprite to a new mineral found at Cornwall, Lebanon Co., Penn. He gives the following description (priv. contrib.):

Amorphous, orange-yellow to orange-red; forms very thin coatings, sometimes rag-like, upon magnetite; soft.

On heating loses water and becomes black; contains water and cuprous oxide. A sufficient quantity for analysis could not be obtained, but its composition is probably $\overline{\mathrm{Cu}}\dot{\mathrm{H}}$. Besides the amorphous coatings, the cuprite variety, *chalcotrichite*, from Cornwall, sometimes assumes an orange-yellow color, so that on the same piece acicular crystals of a fine crimson color can be seen gradually changing to an orange-yellow. It is therefore very probable that the orange crystals are pseudomorphs of hydrocuprite after cuprite.

634 A. Hydrocyanite. Idrociano, *Scacchi*, Note Mineralogiche, I., p. 26, 1873; extract from Atti Accad. Sci. Napoli, v., 1870.

Orthorhombic. Observed planes, i-$\breve{i}$, i-$\breve{2}$, I, 2-$\breve{i}$, 1-$\breve{i}$, 1-$\bar{i}$, 1, $\frac{1}{2}$; a (vert.) : b : c = 0·7968 0·5650 : 1 or 1·7691 : 1 : 1·4104. Fundamental angles, $I \wedge I = 121° 4'$; i-$\breve{i} \wedge 1$-$\breve{i} = 128° 33'$ i-$\breve{i} \wedge 1 = 114° 25'$; i-$\breve{i} \wedge \frac{1}{2} = 108° 2'$.

Color pale green, brownish or yellowish, also sky-blue. Translucent.

An analysis (l. c.) gave $\dot{\mathrm{C}}\mathrm{u}$ 49·47. $\dddot{\mathrm{S}}$ 50·30, loss 0·40 = 100·00, which corresponds to the formula $\dot{\mathrm{C}}\mathrm{u}\dddot{\mathrm{S}}$.

Completely soluble in water. Effloresces very readily in contact with the air. When preserved in the matrix untouched the crystals will remain two or three days without sensible alteration, but upon being detached, or even touched, they change color almost immediately. In the alteration the crystals first show a blue color, then split to pieces slowly, and separate into minute granules, which seem to be crystals, though too small to allow of their form being determined. The cause of the efflorescence in this case is the absorption of the water from the atmosphere, not the loss of water, as is generally true. The change when complete results in the production of chalcanthite ($\dot{\mathrm{C}}\mathrm{u}\dddot{\mathrm{S}} + 7\dot{\mathrm{H}}$).

In the prismatic zone the crystals show no immediate relation to allied sulphates; the angles of the brachydomes, however, agree quite closely, 1-$\breve{i} \wedge$ 1-$\breve{i}$ = 77° 6′, hydrocyanite; 75° 52′, celestite; 75° 35′, anglesite; 74° 34′, barite.

Found by Scacchi at Vesuvius, having been produced by sublimation at the time of the eruption of October, 1868. The name is derived from the ὕδωρ, *water*, κύανος, *azure blue*; an unfortunate name, suggesting a *hydrous* mineral and one relating to cyanite. See also Dolerophanite.

HYDROHALITE. Adam, Tableau Min., 1869, p. 69. A hydrous chlorid of sodium, described by Mitscherlich, Hausmann Min., p. 1459, 1847.

442 B. Hygrophilite, *Laspeyres*, Tsch. Min. Mitth., 1873, p. 147.

Cryptocrystalline. Occurring in scales; double-refracting. H. 2–2·5. G. 2·670. Color greenish-gray to yellowish-gray, in consequence of the presence of minute pores, properly transparent. Often contains minute cubes of pyrite. Lustre and feel greasy. Streak greenish-white.

Analysis, Laspeyres (l. c.)

	$\ddot{\mathrm{S}}\mathrm{i}$	$\overline{\mathrm{A}}\mathrm{l}$	$\overline{\mathrm{F}}\mathrm{e}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{N}}\mathrm{a}$	$\dot{\mathrm{H}}$	
¾	48·42	33·06	3·26	1·15	1·72	5·67	1·36	9·02	= 102·67

It belongs to the pinite group. Oxygen ratio for $\dot{\mathrm{R}} : \overline{\mathrm{R}} : \ddot{\mathrm{S}}\mathrm{i} : \dot{\mathrm{H}}$ = (approximately) 1 : 5 : 9 : 3.

B. B. Fuses rather easily to a white enamel, which, with cobalt solution, takes a blue color. Very hygroscopic. In water falls to pieces gradually like clay. Soluble in hydrochloric acid.

Occurs in large irregular masses distributed in a sandstone, or silicious conglomerate in the neighborhood of Halle an der Saale.

JEFFERISITE, Min. p. 494.—No. Carolina, with corundum, analyses, *Genth*, Am. Phil. Soc. Philad., xiii., 392, 1873.
West Chester, Penn., study of optical character, *Cooke*, Mem. Am. Ac. Boston, 1874, 44.
CULSAGEEITE is a variety of jefferisite described by J. P. Cooke (Mem. Am. Ac. Boston, 1874, p. 48). It very closely resembles the jefferisite from West Chester, Pa., though the color is much lighter, and it is somewhat more friable; the optical properties are the same.
Three analyses gave the following results:

$\ddot{\text{Si}}$	$\overset{\dots}{\bar{\text{A}}\text{l}}$	$\overset{\dots}{\bar{\text{F}}\text{e}}$	$\dot{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{H}}$
37·58	19·73	5·95	0·58	25·13	11·09=100·06
37·43	19·75	5·95	0·58	25·58	11·09=100·38
37·10	20·22	5·95	0·58	25·07	11·09=100·01

Oxygen ratio for $\dot{\text{R}} : \overset{\dots}{\bar{\text{R}}} : \ddot{\text{Si}} : \dot{\text{H}} = 2 : 1 : 1 : 1$. G. = 2·225. These results agree closely with analyses by Genth (l. c.) of the same mineral.
From the Culsagee Mine, near Franklin, Macon Co., N. Carolina.
See also Vermiculite.

JEFFERSONITE, Min. p. 215.—Franklin, N. J., anal., *Pisani*, C. R., lxxvi., 237, 1873.

JEYPOORITE, Min. p. 47 (*Syepoorite*, bad orthogr., *Ross*).—This mineral has been investigated by W. A. Ross with the following results, previous examinations having been made, according to him, upon mixtures: Occurs in small crystalline beads, isometric (Miller), showing the cube, octahedron, and pyritohedron. Color silver-white. Streak blue-black, and semi-metallic, not magnetic. Blowpipe analysis gave 83·2 and 82·5 p. c. cobalt, with evidences of the presence of arsenic and antimony. Ross gives the following as a probable guess at the composition: cobalt 82, antimony 7, arsenic 6, sulphur 5 = 100.

Occurs in a dark gray sand, consisting of one-tenth pyrrhotite, considerable quartz, some chalcopyrite, etc. From the copper mines of Khetree, Jeypoor, province of Rajpootana, India. Proc. Roy. Soc., xxi., 292, 1873.

KEROLITE. See CEROLITE.

447 A. Kerrite, *Genth*, Amer. Phil. Soc. Philad., xiii., p. 396, 1873.
In fine scales, presenting no definite shape under the microscope. Very soft. G. = 2·303 (Chatard). Color pale greenish-yellow, with tint of brown; lustre pearly.
Analysis (l. c.), Chatard (material shown by microscopic examination to be pure).

	$\ddot{\mathrm{Si}}$	$\dddot{\bar{\mathrm{Al}}}$	$\dddot{\bar{\mathrm{Fe}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Ni}},\dot{\mathrm{Co}}$	$\dot{\mathrm{Mg}}$	ign.
⅓	38·29	11·41	1·95	0·32	0·25	26·40	21·25 = 99·87

The oxygen ratio for $\dot{\mathrm{R}} : \dddot{\bar{\mathrm{R}}} : \ddot{\mathrm{Si}} : \dot{\mathrm{H}} = 5{\cdot}4 : 3 : 10{\cdot}3 : 9{\cdot}5$ or $6 : 3 : 10 : 10$, which would give $2(3\dot{\mathrm{R}},\ddot{\mathrm{Si}}) + (\dddot{\bar{\mathrm{R}}},\ddot{\mathrm{Si}}) + 10\,\dot{\mathrm{H}}$.

Exfoliates upon heating, but not to such an extent as jefferisite. B.B. fuses to a white enamel. Decomposed by HCl with separation of silica in pearly scales. Found as an apparent result of the alteration of chlorite at the corundum locality, Culsagee Mine, near Franklin, Macon Co., No. Carolina. Named from Prof. Kerr, State Geologist.

KIESERITE, Min. p. 641.—Hallstadt, anal., *Wieser*, Verh. Geol. Reichs, 1871, 8, p. 130; anal., and cryst. description, *Tschermak*, Ber. Ak. Wien, lxiii., 315, 1871.

495 A. Kjerulfine, v. Kobell, Journ. pr. Ch., II., vii., p. 272, 1873.
Massive, cleavage imperfect in two directions, approximately 90°. H. 4–5. G. 3·15. Translucent in fine splinters. Color pale red. Lustre greasy. Fracture uneven.
Analysis (l. c.), after deduction of SiO_2 (1·50 p. c.) and $Al_2O_3 + Fe_2O_3$ (5·40 p. c.).

$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Na}}$	Fl	$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}}$
40·86	5·96′	1·28	5·28	46·62 = 100

Formula, $2\,\dot{\mathrm{Mg}}_3\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{P}}} + \mathrm{CaFl}$, where some lime is replaced by soda. Stands near wagnerite, but differs in the large percentage of Fl and almost entire absence of lime.
Occurs at Bamle, Norway.

KLAPROTHOLITE, Jahrb. Min., 1868, 415.—Appendix I., p. 8.

KOLLOPHAN. Sandberger, J. pr. Ch., II., ii., 129.—Appendix I., p. 9.

10 A. Kongsbergite *Pisani*, C. R., lxxv., p. 1274, 1872.
An amalgam of silver and mercury occurring with arquerite (analysis l. c. Ag. 96·3, Hg 3·7) at Kongsberg, Norway. Analyses (l. c.) 1. crystalline; 2. crystals.

		Ag	Hg
1.	[illegible]	95·26	4·74
2.	[illegible]	94·94	5·06

These give the formula $Ag_{18}Hg$ (Ag 95·10, Hg 4·90). Pisani suggests the possibility that the occurrence may be accidental, but if not so, and if found at other localities, he suggests the name *Kongsbergite*.

471 A. Koppite, *Knop*, Jahrb. Min., 1875, 67 (ZS. G. Ges., xxiii., 656, 1871).
Occurs with apatite and magnoferrite in a granular limestone near Schelingen, Kaiserstuhlgebirge, Baden. Color brown. Transparent.
Analyses, 1. Bromeis (quoted by Knop from Handwörterb. d. Chemie, VI., 708). 2. Knop (l. c.)

	$\ddot{C}b$	$\dddot{M}o$	$\ddot{T}h$	$\dot{C}e$	$\dot{F}e$	$\dot{M}n$	$\dot{C}a$	$\dot{M}g$	$\dot{K}$	$\dot{N}a$	Fl	$\dot{H}$	
1.	62·03	1·43	10·81		4·48	1·42	14·80	1·58	——	2·37	1·16	1·50	= 101·58
2.	61·90	——	$\dot{C}e$	10·10 ($\dot{D}i,\dot{L}a$)	1·80	0·40	16·00	——	4·23	7·52	——	——	

Each of the determinations of Knop was made on a separate quantity of the mineral. Rammelsberg obtained $\ddot{C}b$ 62·46, $\dot{C}e$ 6·69, $\dot{L}a,\dot{D}i$ 3·00. Knop writes the formula $5\dot{R}\ 2\ddot{C}b$, neglecting a small amount of fluorine. This mineral has been hitherto called pyrochlore, but Knop separates it from that species on the ground that it contains no titanic acid and little or no fluorine. Named in honor of Prof. Kopp, of Heidelberg.

496 A. Korarfveite, *F. Radominski*, C. R., lxxviii., p. 764, 1874. A name proposed provisionally for a phosphate of cerium containing fluorine near monazite. It occurs in albite with gadolinite, hjelmite, and beryl at Korarfet near Fahlun, Sweden (there called monazite).
In imperfect crystals, or crystalline masses often very large; one cleavage perfect. Double refracting (Des Cloizeaux). G. 4·03. Color yellow passing into brown. Fracture vitreous, translucent. Streak grayish-yellow.
Analysis (l. c.) made upon impure material, and consequently needing confirmation.

$\underbrace{\dot{C}e\ \dot{L}a\ \dot{D}i}$	$\dot{C}a$	$\dot{M}g$	$\not{F}e$	Fl	$\ddot{\not{P}}$	$\dot{H}$	
67·40	1·24	tr	0·32	4·35	27·38	tr	= 100·69

B. B., infusible. Partially attacked by HCl with evolution of Cl. Completely decomposed by sulphuric acid and bisulphate of potash.

KOTSCHUBEITE, Min. p. 497.—Relation to *kämmererite*, etc., v. *Leuchtenberg*, Bull. Soc. Imp. St. Pet., xiii., 34, 1869.

Kryokonite. See CRYOCONITE.

LABRADORITE, Min. p. 341.—Examination of the cause of the iridescence, *Vogelsang*, Arch. Néerland, iii., 32, 1868.
Exhaustive cryst. and microscopic investigation by *Schrauf*, in which he shows the presence of inclosed crystals of augite, hematite, and magnetite (with picotite ?). He also describes two varieties of microscopic inclosures to the presence of which the color is due; the first he calls MICROPLAKITE. They form rectangular tabular crystals ($a \wedge a = 90°$, a ∧ secondary plane $=153\frac{1}{2}°-153°$) and lie in a position perpendicular to that of the augite needles. By transmitted light they are grayish-yellow to brownish, by reflected light reddish-green to green and blue (the colors of thin media). Schrauf says that in most of their properties they agree with magnetite, though their apparent insolubility is against that idea. The second kind of inclosures he calls MICROPHYLLITE, they form indistinct crystalline scales, and lie parallel to the direction of the augite crystals; they are from ·05 to ·1 mm. in length, and ·02 to ·04 in breadth; their true nature is doubtful. Ber. Ak. Wien, lx., Dec., 1869.

Labrador, analyses of two varieties; violet (with 11·14 p. c. $\dot{C}a$) and white (with 9 4 p. c. $\dot{C}a$), *Oudemanns*, J. pr. Ch. cvi., 56, 1869.

Contains rubidium and caesium. *J. L. Smith*, Am. J. Sci., II., xlix., 335, 1870.

Vesuvius, anal., *v. Rath*, Pogg., cxlvii., 264; enveloped in sanidin. ibid., Erg. Bd., vi., 381 and 198; see also *Scacchi*, Atti Accad. Napoli, v., March, 1870; Sept. 14, 1872.

Vesuvius, shown by accurate measurements, as well as by the presence of striated faces (due to twining), to be *tetragonal*. The ordinary crystals show the planes 1, 4-2, also 2-i and *I*; *i* ∧ *i* (=4-2 ∧ 4-2)=133° 58′; *a* (vertical)=0·52637; composition face 2-*i*. Also anal., *v. Rath*, Pogg., Erg. Bd., vi., 198, 1873 (or Jahrb. Min., 1873, 113).

Note by *Scacchi*, Boll. Com. Geol. Ital., 1873, 183.

LEUCOPHANITE, Min. p. 260.—Cryst., *Nordenskiöld*, Œfv. Ak. Stockh., 1870, xxvii., 557 Cryst., *Bertrand*, Ann. d. Mines, VII., iii., 24. Cryst., v. Lang, Tsch. Min. Mitth., 1871, p 82.

LEUCOPYRITE, Min. p. 77 (=löllingite, Dana)—and löllingite, anal., Przibram, *Zepharovich*, Lotos, Jan., 1870.

In Dana's Mineralogy, 1868, the names, leucopyrite and löllingite previously used as synonyms, were given, leucopyrite to the mineral with the composition $FeAs_2$, and löllingite to the compound Fe_2As_3 (supposed to include the arsenical pyrites from Lölling, not then known to have been analyzed). It appears, however, that a little earlier, Zepharovich (Verh. Min. Ges. St. Pet., II., iii., 1867) had found the Lölling mineral to have the composition $FeAs_2$, and hence proposed for it the name löllingite, reserving Shepard's name, leucopyrite, for the Fe_2As_3. The names as given by Zepharovich have the priority, and should be received. In another printing from the stereotype plates (6th sub-edition) of Dana's Min. the change will be made. It is to be added, however, that there was no "confounding of the names" (Naumann, Min., p. 611, 1874) in Dana's Mineralogy.

LEVYNITE, Min. p. 431.—Richmond, Vict., comp., *Kenngott*, Jahr. Nat. Ges. Zürich, xvi., 132, 262, 1871.

LIGNITE, Min. p. 755.—Pecton Co., N. S., anal. and description, *How*, Phil. Mag., IV., xxxvii., 264.

414 A. Limbachite, Frenzel, Jahrb. Min., 1873, 789; Min. Lex. Sachsen, p. 184.

Massive. G. = 2·395. Lustre greasy. Color grayish to greenish-white. Not hard nor brittle. Does not adhere to the tongue.

Analyses, Frenzel (l. c.)

$\ddot{\text{Si}}$	$\ddot{\bar{\text{Al}}}$	$\bar{\text{Fe}}$	$\dot{\text{Mg}}$	$\dot{\text{H}}$
41·42	22·09	——	23·67	12·47 = 99 65
42·03	19·56	1.46	25·61	12·34 = 101·00

Frenzel gives the formula $3\dot{\text{Mg}}\,2\ddot{\text{Si}} + \ddot{\bar{\text{Al}}}\ddot{\text{Si}} + 3\dot{\text{H}}$. Hence in oxygen ratio it stands very near cerolite (Kerolith), from which species Frenzel has separated it, though, as he shows, the analyses vary much. $\dot{\text{R}} : \ddot{\bar{\text{R}}} : \ddot{\text{Si}} : \dot{\text{H}} = 1 : 1 : 3 : 1$.

Occurs at Limbach, filling cavities or fissures in serpentine.

A similar mineral, occurring in serpentine at Zöblitz, has been called **ZÖBLITZITE** by Frenzel (Min. Lex. Sachsen, p. 351). Massive. Color light-yellow. An analysis gave Melling (l. c. and Jahrb. Min., 1873, 789), $\ddot{\text{Si}}$ 47·13, $\ddot{\bar{\text{Al}}}$ 2·57, Fe 2·92, $\dot{\text{Mg}}$ 36·13, $\dot{\text{H}}$ 11·50 = 100·25.

LIMBILITE, Min p. 258.—Rosenbusch thinks that the limbilite of de Saussure cannot be regarded as a result of the decomposition of chrysolite, but rather of the glassy matter of such a rock as has been called by him limburgite, Jahrb. Min., 1872, 169.

LIME-WAVELLITE, *Kosmann*, ZS. G. Ges., xxi., 795, 1869.—Appendix I., p. 9.

LITHIOPHORITE, Appendix I., p. 9.—*Laspeyres*, Jahrb. Min., 173, 1869.

29 A. Livingstonite, *Mariano Barcena*, Naturaleza, iii., 35, 1874; iii., p. 172, 1875, Am. J. Sci., III., viii., p. 145, 1874; ix., p. 64, 1875.

In prisms, and columnar groups much like stibnite, and apparently isomorphous with it. H. = 2 (Breithaupt's scale). G. = 4·81. Color bright lead-gray. Streak *red* (not black as with stibnite). Analysis, Barcena (l. c.)

S	Sb	Hg	Fe
29·08	53·12	14·00	3·50 = 99·70

Whence the atomic ratio for the sulphur, antimony, mercury and iron, 18·17 : 8·7 : 1·4 · 12 = (nearly) 15 : 7 : 1 : 1, or $4SbS_3 + HgS + FeS^2$. Fuses at the first touch of the blowpipe flame, giving off white fumes in abundance. Not sensibly attacked by cold nitric acid, but dissolved in the warm acid with a white residue.

Occurs at Huitzuco, State of Guerrero, Mexico, in a matrix of carbonate and sulphate of lime, together with sulphur, cinnabar, stibnite and valentinite.

LÖLLINGITE, Min. p. 76 (= leucopyrite, Dana).—Reichenstein, Silesia, anal. (containing gold), Güttler, Jahrb. Min., 1871, 81.

Chañarcillo, anal., Domeyko 3d Append. Min. Chili, 1871.

Dobschau, Hungary, anal., *Niedzwiedzki*, Tsch. Min. Mitth., 1872, 161.

See also Leucopyrite.

595 A. Ludwigite, *G. Tschermak*, Tsch. Min. Mitth., 1874, p. 59.

In finely fibrous masses, the fibres generally short and in a parallel position, so that on the fresh fracture it has a silky lustre. H. = 5. G. = 3·907–3·951 (lighter colored variety), 4·016 (dark-colored variety). Color blackish-green, and again almost perfectly black with a tinge of violet. Tough. Streak dark-green, of a somewhat lighter color than the mineral itself. In microscopic splinters transparent, with a greenish-brown color.

Analysis, Ludwig and Sipöcz, l. c. 1. (mean of 7 partial analyses) G. = 3·951, color dark-green. 2. G. = 4·016, black.

	$\dddot{B}$	$\dddot{\overline{Fe}}$	$\dot{Fe}$	$\dot{Mg}$
1.	16·09	39·92	12·46	31·69 = 100·16*
2.	15·06	39·29	17·67	26·91 = 98·93*

* Traces of manganese.

For analysis 2. Tschermak gives the formula $2\dot{Mg}\dddot{B} + \dot{Fe}\dddot{\overline{Fe}}$, which corresponds also to analysis 1, though here a little $\dot{Mg}$ takes the place of some $\dot{Fe}$.

A microscopic examination proved the absence of magnetite in the material analyzed, though magnetite and also sometimes calcite are generally intimately associated with it.

Heated in the air the mineral becomes red; in fine splinters fusible with difficulty to a black, strongly magnetic, slag. With the fluxes gives the reaction for iron. Dissolved slowly by cold hydrochloric acid when in the state of a fine powder.

Occurs imbedded in a crystalline limestone, with irregularly situated beds of magnetite, at Morawitza in the Banat.

According to F. Berwerth (Tsch. Min. Mitth., 1874, 247) ludwigite occurs altered to limonite. An analysis of material, having a brownish-red color, and graduating insensibly into pure ludwigite, afforded him: $\dddot{\overline{Fe}}$ 75·84, $\dot{Mn}$ tr., $\dot{Ca}$ 0·09, $\dot{Mg}$ 5·80, $\ddot{C}$ 1·65, $\ddot{Si}$ 2·83, $\dot{H}$ 14·51, $\dddot{B}$ 0·08 = 101·02. G. = 3·41. Besides the limonite (88·17 p. c.), Berwerth considers that some talc, brucite, magnesite, and calcite are also here present as mechanically mixed impurities.

LÜNEBURGITE, Nöllner, Ber. Ak. München, 1870, 291.—Appendix I., p. 10.

132. Luzonite, *Weisbach*, Tsch. Min. Mitth., 1874, p. 257.

Massive, with uneven fracture, with but little tendency to cleavage. In cavities there were also observed some minute crystals, whose form could not to be distinguished. H. = 3·5 G. = 4·42. Color dark reddish-steel gray, turning violet with time. Lustre black and metallic. Streak black. Brittle.

Analysis, Winkler, l. c.

S	Sb	As	Cu	Fe
33·14	2·15	16·52	47·51	0.93 = 100·55

This gives substantially $Cu_3AsS_4 = 3\,\overline{Cu}S + As_2S_5$, or similar to enargite

It is closely related to famatinite (q. v.) and Weisbach says, though without sufficient reason, that the two are probably isomorphous, while it forms a dimorphous group with enargite. The sole reason for separating the mineral from enargite seems to be its structureless character, nearly destitute of cleavage, but, unsupported by observations on the crystalline form, this cannot be regarded as conclusive.

Occurs in the copper veins of Mancayan, district of Lepanto, Island Luzon (Manila). Associated with the following minerals, named in the order of their deposition: Quartz, pyrite, (luzonite), enargite, quartz, tetrahedrite, barite.

447 B. Maconite, *Genth*, Amer. Phil. Soc., Philad., xiii., 396, 1873.

In irregular scales, resembling a variety of jefferisite. Soft, but slightly harder than kerrite. G. = 2·827 (Chatard). Color dark brown; lustre pearly, inclining to sub-metallic. Analysis, l. c., Chatard and Genth.

	$\ddot{\mathrm{Si}}$	$\dddot{\mathrm{Al}}$	$\dddot{\mathrm{Fe}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Ni}}$,Co	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Li}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	ign.
$\frac{2}{3}$	34·22	21·53	12·41	0·32	0·12	14·46	tr	0·51	5·70	11·85 = 101·19

Oxygen ratio, $\dot{\mathrm{R}} : \dddot{\mathrm{R}} : \ddot{\mathrm{Si}} : \dot{\mathrm{H}} = 3 : 6 : 8 : 5$ nearly, or $3\dot{\mathrm{R}}, 2\ddot{\mathrm{Si}} + 2(\dddot{\mathrm{R}}, \ddot{\mathrm{Si}}) + 5\dot{\mathrm{H}}$.

Exfoliates largely on heating, and fuses with difficulty to a brown glass; easily decomposed by hydrochloric acid, with separation of silica in scales.

Contains numerous fragments of corundum, and some microscopic reddish-brown crystals which may be sphene. Found, as an apparent result of the alteration of chlorite, at the corundum locality, Culsagee Mine, near Franklin, Macon Co., No. Carolina.

Brewster, N. Y., pseudomorph after dolomite and chondrodite, *J. D. Dana*, Am. J. Sci., III., viii., 375, 1874.

In mica from Pennsbury, reply of *J. D. Dana* and *G. J. Brush* to a note by Rose (see hematite), Am. J. Sci., II., xlviii., 360, 1869 (Jahrb. Min., 1874, 611).

Both Zirkel (Microscop. Beschaff. der Min., 1873, p. 247) and Rosenbusch (Phys. d. Min., 1873, p. 213) speak of the mineral in the mica of Pennsbury as being hematite. It is difficult, however, to see how this view can be reconciled with the investigations of Brush (l. c.). He found that the mineral was blackish to smoky-brown in color, and strongly magnetic. It had moreover a black streak. Upon being heated to redness out of contact of the air it retained its color, but heated with access to the air it became red. It was sometimes, in consequence of alteration, changed to a bright red or yellow mineral. The red substance had a red streak, the yellow substance an ochre-yellow streak; the last became red when heated. Prof. Brush concludes that the black mineral is in all probability magnetite, the red mineral is hematite (arising from the oxidation of the original magnetite), and the yellow-ochre mineral is hydrated sesquioxyd of iron, due to hydration as well as oxidation.

189. Magnochromite, *Bock*, Inaug. Dissert. Breslau, 1869. *Websky*, ZS. G. Ges., xxv., 394, 1873.

A variety of chromite from Grochau, Silesia, containing a large amount of magnesia. It has been previously described by Breithaupt (1832, III., p. 234; 1847, III., 777), and also by other authors. In physical characters it agrees with chromite, except in its want of metallic lustre and low specific gravity. According to Breithaupt G. = 4·031–4·110 (this, Websky suggests, is in part accounted for by the presence of impurities). It occurs in rounded grains embedded in a green gangue from which it cannot be entirely separated. This gangue mineral is considered by Websky as a new species, and using an analysis of it (v. grochauite) he deducts it from an analysis of a mixture of the two, made by Bock, and obtains the following as the composition of the magnochromite: $\dddot{\mathrm{Al}} = 29·92$, $\dddot{\mathrm{Cr}} = 40·78$, $\dot{\mathrm{Fe}} = 15·30$, $\mathrm{Mg} = 14·00 = 100·00$. This result agrees with the general formula $\dot{\mathrm{R}}, \dddot{\mathrm{R}}$ of the spinel group giving in this case $4(\dddot{\mathrm{Al}}, \dddot{\mathrm{Cr}}).(3\dot{\mathrm{Fe}}, 5\dot{\mathrm{Mg}})$.

MALACHITE, Min. p. 715.—Pseudomorph after atacamite, *Kokscharow*, Bull. Soc. Imp. St Pet., xviii., 186, 1872; *Tschermak*, Min. Mitth., 1873, 39.

MALDONITE, *Ulrich*.—Appendix I., p. 10.

MANGANDISTHEN. See ARDENNITE.

290 A. Manganophyllite, *Igelström*, Jahrb. Min., 1872, 296, (Kenngott, 1873, 56).
Hexagonal? In thin plates, like other micas.
Color bronze to copper-red. Streak pale red. In thin scales translucent with a rose-red color.
Analysis, Igelström (l. c.)

S̈i	Ⱥl	Ḟe	Ṁn	Ċa	Ṁg	K̇,Ṅa	ign.		
38·50	11·00	3·78	21·40	3·20	15·01	5·51	1·60	=	100

Kenngott observes (l. c.) that, if we call the loss Ḣ and reckon it with the bases, the oxygen ratio for bases to silica becomes 11·72 : 12 or Ṙ : R̶ : S̈i=1 : 3 : 4 nearly (the ratio of lepidomelane). The alkalies appear to be for the most part potash.
B. B. gives no coating on charcoal; with borax or soda affords a strong manganese reaction. Soluble in HCl with the separation of silica in the form of the original scales.
Occurs with tephroite, hydrotephroite, hamartite, magnetite, calcite, garnet, etc., at the manganese mine Pajsberg, near Filipstadt, Sweden.
Igelström calls attention to the fact that his manganophyll is in many respects similar to the imperfectly described (no analysis) alurgite of Breithaupt (Dana's Min. p. 764).

MARCASITE, Min. p. 75.—Pseudomorph after bournonite, chalcopyrite, magnetite, *Döll*, Tsch. Min. Mitth., 1874, 87, 88.
(Weisskupfererz) Halsbrüche, near Freiberg, an analysis by *Frenzel* gave results agreeing with the formula R_2S_3 (Cu=10·75 p. c., Fe=40·47), it is a compound between marcasite and chalcopyrite, and, if constant in composition, Frenzel suggests that it should have a distinctive name, Jahrb. Min., 1873, 785.

MARCELINE, Min. p. 163.—Examined by *v. Kobell*, J. pr. Ch., II., iii., 467.

MARGARITE, Min. p. 506.—No. Carolina, anal., *J. L. Smith*, Am. J. Sci., III., vi., 184; analyses, *Genth*, Am. Phil. Soc., Philad., xiii., 399, 1873.
Optical character investigated, *Bauer*, ZS. G. Ges., xxvi., 180, 1874.

Mariposite, a name proposed provisionally by Prof. Silliman for an anhydrous silicate containing as bases, according to the blowpipe, iron (protoxide), alumina, chromium, lime, magnesia and potash, with traces of manganese and sulphuric acid. It had a light apple-green color, occurs in scales and associated with pyrite in a gangue of dolomite (ankerite) mingled with quartz; from the Mariposa estate, California. (Cal. Acad. Sci., III., 380, 1868). It has since been referred provisionally to fuchsite (Min p. 811, anal., 16), though its identity with that species has not been finally determined. It is the constant associate of the ore through the Mariposa region, and in consequence of its paragenetical relations deserves further investigation.

MARMOLITE, Min. p. 465. See SERPENTINE.

MARTITE, Min. p. 142.—Brazil, *Rosenbusch*, Jahrb. Min., 1871, 78.

339 A. Maskelynite, Tschermak, Ber. Ak. Wien, lxv., p. 122, 1872.
Isometric; form a distorted cube. In grains transparent, colorless, with milky portions arising from alteration. In the microscopic section seen to have a rectangular outline, and shown by optical properties to be isometric. H. = about 6·5. B. B., fusible with difficulty to a transparent glass. Analysis, mean of two closely agreeing analyses made by different methods:

S̈i	Ⱥl	F̶eFe	Ca	Mg	Na	K		
54·3	24·8	4·7	11·1	tr	4·9	1·2	=	101·0

The iron comes from a little magnetite present, and deducting this we obtain: S̈i 56·3, Ⱥl 25·7, Ċa 11·6, Ṅa 5·1, K̇ 1·3 = 100·00.
The oxygen ratio is nearly Ṙ : R̶ : S̈i = 1 : 3 : 6, or that of labradorite.
Occurs in the meteorite from Shergotty, near Behar, India.

635 A. Maxite, *Laspeyres*, Jahrb. Min., 1872, 407, 508; 1873, 292.
Orthorhombic. Massive, crystalline. Cleavage tabular, perfect.

Optical characters—acute bisectrix normal to the cleavage surface. Double-refraction strong, character negative. Axial angle small. Apparent angle in air for red rays 19° 38′; for blue 22° 45′; for white 20° 51′. H. = 2·5–3. G. = 6·87 (leadhillite 6·26–6·44; 6·60, Sardinia, *Bertrand*). Colorless. Transparent to translucent. Lustre adamantine to pearly. Fracture conchoidal to splintery. Slightly brittle.

Analysis, Laspeyres and Eichhorn (l. c.)

$\dot{\mathrm{P}}\mathrm{b}$	$\dddot{\mathrm{S}}$	$\ddot{\mathrm{C}}$	$\dot{\mathrm{H}}$
81·91	8·14	8·08	1·87 = 100·00

Laspeyres writes the formula $5\dot{\mathrm{P}}\mathrm{b}\dddot{\mathrm{S}} + 9\dot{\mathrm{P}}\mathrm{b}\ddot{\mathrm{C}} + 4\dot{\mathrm{P}}\mathrm{b} + 5\dot{\mathrm{H}}$, making it a hydro-sulpho-carbonate of lead.

Fuses easily in the flame of a spirit lamp, forming a yellow bead, crystalline on cooling. On charcoal gives a lead coating. In the matrass decrepitates, expands and becomes white and non-transparent, giving off water. Insoluble in water. Soluble in nitric acid.

Occurs with anglesite and cerussite in galenite at the Mala-Culzetta mine near Iglesias, Sardinia.

Maxite resembles leadhillite very closely in its physical characters, especially in its optical properties, and is not far off in composition. Bertrand, on this account, has urged that the maxite is probably nothing but an altered leadhillite (Bull. Soc. Chem., xix., 17, 1873), which seems not improbable.

In dolerytes of Bergonne, analyses, *Pisani*, C. R., lxxiii., 1447, 1871.
In basalts, *Streng*, Jahrb. Min., 1874, 575.

METACINNABARITE, *Moore*, Am. J. Sci., III., iii., 36. Appendix I., p. 10.
Durand thinks, after an examination of some good crystals, though without the opportunity of making measurements, that there is a strong presumption in favor of the mineral being orthorhombic. He gives two figures, which, however, look much like a combination of the cube and octahedron, *i.e.*, isometric, as before suggested. Proc. Cal. Acad., iv., 219, 1872.

225 A. Meymacite, *Carnot*, C. R., lxxix., p. 639, 1874.
A hydrated tungstic acid, formed from the alteration of scheelite, which Carnot suggests, may have been accomplished by means of acid waters arising from the decomposition of pyrite.

Sometimes yellow or greenish-yellow, preserving the crystalline structure and cleavage of scheelite; sometimes when the alteration has been more complete, the mineral is friable between the fingers, and has a yellow or brownish color. Lustre resinous.

Analyses (l. c.) 1. and 2. on friable material, color yellow to brownish, streak sulphur yellow. G. = 3·80. 3. firm, with lamellar structure and yellowish streak. G. = 4·54.

$\dddot{W}$	$\dddot{\overline{Ta}}$	$\dddot{\overline{Fe}}$	$\dot{\overline{Mn}}$	$\dot{Ca}$	$\dot{H}$	gangue
71·85	1·00	6 00	0·75	2·50	12·93	4·50 = 99·53
74·25	1·05	6·10	0·65	4·65	11·75	1·85 = 100 30
75·12	0·70	6·25	0·32	7·00	6·85	2·55 = 98·79

Deducting the tungstate of lime and hydrated oxyd of iron, which he regards as impurities, Carnot deduces the formula $\dddot{W}, 2\dot{H}$. In the tube gives off water. On charcoal turns black. With salt of phosphorus, gives in the O. F. a yellow bead, nearly colorless on cooling. In R. F. a bead colored violet to red (iron and tungstic acid together). With acids gives the reaction of tungstic acid when treated in the usual way.

Found with wolfram and scheelite at Meymac (Corrèze), France.

MICA, Min. p. 301 et seq.—Milben, near Petersthal, anal., *Nessler*, Jahrb. Min., 1869, 949.

MICHAELSONITE, Min. p. 289.—(Erdmannite, *Blomstrand*), composition and description *Nordenskiöld*, Œfv. Ak. Stockholm, 1870, xxvii., 365.

MICROLITE, Min. p. 513.—Shepard Am. J. Sci., II., l., 95, 1870.

MICROLITES, a name proposed by Vogelsang (Philosoph. d. Geol., 1867, p. 139) and since used by Zirkel (Mikroscop. Beschaff. d. Min., 1873, pp. 33, 88) for microscopic crystals, sometimes belonging to known species, sometimes of indeterminate nature, but often observed in igneous rocks. The method of aggregation of these microlites is sometimes very remarkable. Trichite and belonite are names given by Zirkel (l. c.) to analogous forms.

Mikroplakite, Mikrophyllite. See LABRADORITE.

305 A. **Microsommite.**—Scacchi, Rend. R. Accad. Napoli, Oct., 1872, ZS. G. Ges., xxiv., 506. Further investigated by v. Rath, Pogg., Ann. Erg. Bd, vi., p. 372, 1873.

Occurs in extremely minute hexagonal crystals; often grouped together. Crystals striated vertically, occasionally with edges truncated. *O* dull. *a* (vert.) = ·347. 1 ∧ *I*=111° 50′; 1 : 1 (over *I*)=43° 40′; 1 : 1 (adj.) 158° 34′ (angles only approximate).

H. 6. G. 2·60. Transparent. Colorless. Analysis (on 0·1 gr. consisting of 1500 crystals).

$\ddot{Si}$	$\dddot{\overline{Al}}$	$\dot{Ca}$	$\dot{K}$	$\dot{Na}$	Cl	$\dddot{S}$		
33·0	29·0	11·2	11·5	8·7	9·1	1·7	=	104·2

If the Na belongs to the Cl the excess is diminished 2 p. c. Oxygen ratio for $\dddot{\overline{R}}$: $\ddot{Si}$=3 : 4.

B. B. fusible with difficulty. No loss by violent ignition; in hydrochloric acid decomposed with separation of gelatinous silica. Occurs at Vesuvius in ejected masses, and formed by sublimation in the leucitic lava. It is closely related to sodalite.

Milanite. See HALLOYSITE.

MILARITE, Kenngott, Jahrb. Min. 1870, 81.—Appendix I., p. 10.

Kenngott suggests that milarite may be identical with levynite (but see below), Jahr. Nat. Ges. Zürich, xvi., 132, 1871.

According to Frenzel the locality is Val Giuf, Graubünden, *not* Val Milar. He has made an analysis with the following results: 1. G.=2·59. Analysis 2. is by Finkener (Eck, Jahrb Min., 1874, 62). G.=2·5.

	$\ddot{Si}$	$\dddot{\overline{Al}}$	$\dot{Ca}$	$\dot{Mg}$	$\dot{Na}$	$\dot{Ka}$	$\dot{H}$	
1.	71·12	8·45	11·27	——	(7·61)	——	1·55 = 100·00	Frenzel.
2.	70·04	11·62	10·05	0·20	0·65	5·74	1·69 = 99·99	Finkener.

The water is driven off only at a high temperature; Frenzel regards it as basic, and suggests that the mineral belongs near petalite (Jahrb. Min., 1873, 797).

Can the excess of silica be due to impurity?

Millerite, Min. p. 56.—Anal., *Liebe*, Jahrb. Min., 1871, 843.

Miloschite, Min. p. 510.—May be a mixture, *Kenngott*, Jahr. Nat. Ges. Zürich, xvii., 66

Mimetite, Min. p. 537.—Nador, province Constatine, anal., *Flajolot*, ZS. G. Ges., xxiv. 49, 1872.

Miriquidite, Frenzel, Jahrb. Min., 1874, p. 673 (1873, 939).

Rhombohedral, a (vert)$=3\cdot363$. Planes R and $-\frac{1}{2}R$, $R\wedge-\frac{1}{2}R=123°$, $R\wedge R=66°$ and $114°$. Crystals very minute and hence measurements only approximate. Plane R often horizontally striated, and somewhat curved (cryst. descript. by vom Rath). Also massive in imbedded portions having a yellowish to reddish brown color. Color of crystals blackish-brown, on edges red by transmitted light. Streak ochre-yellow. Lustre glassy. Translucent to opaque. Brittle.

H.$=4$. Contains $\dot{\mathrm{P}}\mathrm{b}$, $\dddot{\mathrm{F}}\mathrm{e}$, $\overset{\cdots}{\bar{\mathrm{A}}}\mathrm{s}$, $\overset{\cdots}{\bar{\mathrm{P}}}$, $\dot{\mathrm{H}}$, but the want of sufficient quantity of pure material prevented an analysis.

B. B., fusible to a globule, coloring the charcoal yellow. In matrass gives water, and with the fluxes reacts for iron. The presence of the acids is less easily proved, and Frenzel concludes that it is probably a very basic compound.

Found at Schneeberg with chalcocite, pyromorphite, cuprite, torbernite, etc.

Mispickel, Min. p. 78.—See Arsenopyrite.

Nadorite, *Flajolot*, C. R., lxxi., 237, 406.—Appendix I., p. 11.

Namaqualite, *Church*, J. Ch. Soc., II., viii., 1.—Appendix I., p. 11.

Nantoquite. Breithaupt gives the following description of this mineral (Nantokite) previously announced by him, B. and H. Ztg., xxvii., 3, see Dana's Min. Appendix I., p. 11. Isometric, as proved by the cubic cleavage, though no crystals were observed. Granular, massive. H. $=2$–$2\cdot5$. G. $=3\cdot930$. Color white to colorless. Lustre adamantine.

Analyses give the formula Cu_2Cl or $Cu_2=64\cdot11$, $Cl=35\cdot89$.

On charcoal fuses, coloring the flame intense azure blue, leaving a coating of oxyd of silver, and a white coating farther from the assay; a ductile globule of copper remains on the coal. Easily soluble in nitric or hydrochloric acid, as also in ammonia. Rapidly decomposed on exposure to the air. Jahrb. Min., 1872, 814.

This mineral was first described by Dr. Sieveking, see Domeyko 2d Append. Min. Chili, p. 51, Feb., 1873. A more recent analysis (3d Append., 1871) gave Cu_2Cl $79\cdot32$, $\dot{C}u_2$ $12\cdot56$.

mol. 3·30, $\overline{\text{F}}\text{e}$ 0·05 = 95·23. Domeyko mentions that the mineral is remarkable for evolving in the mine an odor of chlorine which incommodes the miners. This, he says, is due to the production of ozone, which accompanies the oxidation of the Cu_2Cl.

NATROLITE, Min. p. 426.—Composition discussed, *Rammelsberg*, ZS. G. Ges., xxi., 96, 1868.
Loch Thorn, Greenock, anal., *Young*, Chem. News, xxvii., 55, 1872.
Stempel, anal. (*Klippert*), *v. Koenen*, Jahrb. Min., 1875, 87.

404 E. **Nefedieffite,** *P. Pusirewsky* (Verh. Min. Ges. St. Petersburg, II., vii., 1872), in Jahrb. Min., 1873, 420.
Amorphous, very similar to lithomarge (Steinmark). H. = 1·15. G. = 2·335. Fracture conchoidal. Color white to rose-red. Opaque, on the edges translucent. Feel greasy. Several analyses (not quoted in Jahrb. Min.) gave very discordant results, but their mean agrees most closely with the formula $H_6MgAl_2Si_5O_{17}$, although Pusirewsky prefers, on account of its simplicity, the formula $H_4MgAl_2Si_5O_{16}$, though it agrees even less well with the analyses. Scarcely soluble in acids. In water 0·2 p. c. dissolves, the solution giving an alkaline reaction; over sulphuric acid 11·30 p. c. H_2O is given off (in 22 days), which it again absorbs on exposure to the air. At 250° C. it loses 19·18 p. c. H_2O, and 4·73 p. c. more when heated to the melting point.

NIGRESCITE, *Hornstein*, ZS. G. Ges., 1867, 342.—Appendix I., p. 12.

NIOBITE. Synonym of columbite used by Rammelsberg.

Nitroglauberite. From Atacama (Dr. Schwartzemberg). Composition, $4\dot{\text{N}}\text{a}\dddot{\text{S}} + 6\dot{\text{N}}\text{a}\overset{\dots}{\text{N}} + 5\dot{\text{H}}$. An analysis gave $\dot{\text{N}}\text{a}\dddot{\text{S}}$ 33·90, $\dot{\text{N}}\text{a}\dddot{\text{S}}$ 60·35, $\dot{\text{H}}$ 5·75. Occurs in a fibrous, translucent mass, or consisting of imperfect crystals; permanent in the air. When dissolved with just sufficient water at 40° to 50° C., the double salt separates out unchanged on cooling; but treated with cold water in quantity insufficient to dissolve the whole, the salt is decomposed into crystals of mirabilite, and soda-nitre which remains in solution. Also found by Domeyko at Paposo, 3d Append. Min. Chili, 1871.

478 A. **Nohlite,** *Nordenskiöld* (Geol. För. Stockholm, Förhandl. I., p. 7), Jahrb. Min., 1872, 584.
Massive. H. = 4·5–5·0. G. = 5·04. Color black-brown. Streak brown. Fracture uneven, splintery. Opaque. Brittle. Vitreous lustre.
Analysis.

$\ddot{\text{C}}\text{b}$	$\dot{\text{U}}$	$\ddot{\text{Z}}\text{r}$	$\dot{\text{F}}\text{e}$	$\dot{\text{C}}\text{u}$	$\dot{\text{C}}\text{e}$	$\dot{\text{Y}}$	$\dot{\text{M}}\text{g}(\dot{\text{M}}\text{n})$	$\dot{\text{C}}\text{a}$	$\dot{\text{H}}$
50·48	14·43	2·96	8·09	0·11	0·25	14·36	0·28	4·67	4·62 = 100·20

Corresponding approximately to the formula $\text{R}^3\ddot{\text{C}}\text{b} + 1\tfrac{1}{2}\dot{\text{H}}$.

B.B., fuses quietly on the edges to a dull glass. Decrepitates slightly in giving off its water. With borax easily dissolved, giving a bead colored by uranium. Easily decomposed by warm sulphuric acid.

Found in a feldspar quarry at Nohl, near Kongelf, Sweden. One fragment weighing 297 grs. seemed to be a portion of a mass at least 20 times as great.

Nohlite stands near samarskite, but differs from it in its percentage of water.

NONTRONITE, Min. p. 461.—(Chloropal, Dana), anal., *Thorpe*, J. Ch. Soc., II., viii., 29, 1870.

NOSITE (nosean), Min. p. 338.—A variety of hauynite = a soda-hauynite; discussion of relation to hauynite and lapis lazuli, *Vogelsang*, Vers. Med. Ak. Amsterdam, II., vii. 161, 1873.

OCTAHEDRITE, Min. p. 161.—Binnenthal, cryst., *Klein*, Jahrb. Min., 1872, 900; 1874, 961. Found at Pfitsch Joch, Tyrol, Tsch. Min. Mitth., 1873, 49.

OKENITE, Min. p. 398.—(Dysclasite), Poonah, India, anal., *Haughton*, R. Geol. Soc. Dublin, II., 414, 1868.

OKTIBBEHITE, Min. p. 16.—In meteoric irons, *Meunier*, Ann. Ch. Phys., IV., xvii., 35.

56 A. Oldhamite, *Maskelyne*, 1862; Phil. Trans. London, 1870, I., p. 195. In small, nearly round spherules (generally coated by sulphate of lime as result of alteration). They have three equal cleavages, at right angles to each other; shown by this fact to be isometric, as also because it gives no evidence of double refraction in polarized light. H. = 4. G. = 2.58. Color pale chestnut-brown, transparent when pure.

Analysis (l. c.) after deducting foreign matter (enstatite, etc.).

	Oldhamite		Incrustation				
	CaS	MgS	$\dot{\mathrm{Ca}}\bar{\bar{\mathrm{S}}}$	$\dot{\mathrm{Ca}}\ddot{\mathrm{C}}$	troilite		
1.	89·37	3·25	3·95	3·43	——	=	100·00
2.	90·25	3·26	4·19	——	2·30	=	100·00

Maskelyne suggests that the MgS may be considered either as a mechanically mixed ingredient, or as a constituent of the mineral. Readily dissolved in acid with the evolution of sulphuretted hydrogen and deposition of sulphur. Found imbedded in enstatite or augite in the Busti meteorite, and apparently also in that of Bishopville.

OLIGOCLASE, Min. p. 346.—Vesuvius, cryst., and anal., *v. Rath*, Pogg., cxxxviii., 464, 1869.

Stebnik, Galicia, analyses, *v. Lill*, Tsch. Min. Mitth., 1874, 89.

PREDAZZITE, Min. p. 708.—According to *Hauenschild* (Ber. Ak. Wien, lx., 795, 1869) *predazzite* and *pencatite* are both mixtures of calcite and brucite. The same conclusion was reached by *Damour*, Bull. Soc. G., France, II., iv., 1050. The subject has been further investigated by *Lemberg* (ZS. G. Ges., xxiv., 229, 1872) with conclusive results. According to the latter the black color is due to the presence of finely divided pyrite (not organic matter, as urged by Hauenschild).

PREHNITE, Min. p. 410.—Composition, analyses, *Rammelsberg*, ZS. G. Ges., xx., 79.
Slate river, L. Superior, anal., *Chapman*, Can. Journal, II., xii., 267, Nov., 1869.

600 A. **Priceite.** Cryptomorphite (?), *Chase*, Am. J. Sci., III., v., 287; Priceite, *Silliman*, Am. J. Sci., III., vi., 128.

Compact, chalky, the powder consisting of minute rhombic crystals. Soft. G. = 2·262–2·298. Color milk-white, without lustre. Feel greasy and unctuous.

Analyses, 1. Silliman, l. c. 2. Chase, variety found in bowlders. 3. Chase, from veins.

		$\bar{B}$	$\dot{C}a$	$\dot{H}$	NaCl, $\bar{F}e$, $\bar{A}l$	
1.	⅔	(48·82)	31·83	18·29	·96	= 100·00
2.		(47·04)	29·96	22·75	alkalies ·25	= *100·00
3.		(45·20)	29·80	25·00	“ tr.	= 100·00

* Trace Cl.

Silliman gives as the probable formula $\dot{C}a^3\bar{B}^4 + 6\dot{H}$.

B.B. gives a green flame, and fuses at a red-heat. In the matrass gives off neutral water. Insoluble in water, but perfectly so in hydrochloric acid.

Found in a hard, compact form in layers, between a bed of slate above, the cavities and fissures of which it filled, and a tough blue steatite below; also occurring in bowlders or rounded masses completely imbedded in the steatite. These masses in the main flow formed a continuous line touching each other, and of uniform size, weighing about 200 lbs. each. Branching off from the main deposit were side flows where the bowlders were smaller, from a weight of 20 lbs. down to small pellets the size of a pea, or even smaller.

Locality, Curry Co., Oregon, five miles north of Chetko.

Galenstock, Wallis, crystals with the basal plane, *Bauer*, ZS. G. Ges., xxvi., 194, 1874.

Containing water, the so-called *enhydros*, occurrence and character described, Beechworth, Victoria, *Dunn*, p. 32; *Foord*, p. 71, Trans. Roy. Soc. Victoria, x., 1874.

Remarkable association with calcite, *v. Rath*, Ber. Ak. Berlin, 1874, 683.

Crystalline form discussed, *Kenngott*, Jahrb. Min., 1875, 27.

RABDIONITE, *v. Kobell*, Ber. Ak. München, Jan., 1870.—Appendix I., p. 13.

RALSTONITE, *Brush*, Am. J. Sci., III., ii., 30.—Appendix I., p. 13.

Nordenskiöld has further investigated the ralstonite from Ivituk, Greenland, and obtained the following results, agreeing essentially with the description given by Brush (l. c.). H. = 4·5. G. = 2·62 (on 0·13 gr.). Characters as described by Brush.

Analysis (on 0·221 gr.).

Al	Ca	Mg	Na	Ka	$\ddot{P}$	O Fl	$\dot{H}$
22·94	1·99	5·52	4·66	tr	tr	$\underbrace{(50\cdot05)}$	14·84 = 100

Nordenskiöld finds that if the loss be considered as being fluorine alone, it is insufficient to combines with the bases, so that he concludes there must also be oxygen present.

He writes the formula

$$\left.\begin{matrix}Mg\\3Ca\\Na\end{matrix}\right\}Fl\,\text{Ꞁ}\!Al\,Fl_3+\left.\begin{matrix}\dot{M}g\\2\dot{C}a\\\dot{N}a\end{matrix}\right\}\ddot{A}l+10\dot{H}$$

He also suggests the following formula, after the type of the spinel group, which it resembles in crystalline form: $R\,\text{Ꞁ}\!Al\,(O,Fl)_4+2\dot{H}$.

RAMMELSBERGITE, Min. p. 77.—Anal., *Sandberger*, Ber. Ak. München, 1871, 202.

377 A. Rauite, *Paykull*, Ber. Chem. Ges. Berlin, 1874, p. 1334.

Not crystalline. Structure finely granular. Color grayish-black Without lustre. H. = 5. G. = 2·48. An analysis gave, $\ddot{S}i$ 39·21, $\ddot{A}l$ 31·70, $\ddot{F}e$ 0·57, $\dot{C}a$ 5·07, $\dot{N}a$ 11·15, $\dot{H}$ 11·71 = 99·90. The oxygen ratio for $\dot{R}:\ddot{R}:\ddot{S}i:\dot{H}=1:3:3\frac{1}{3}:2$, or near that of thomsonite. B.B. fuses with difficulty on thin edges.

Occurs on the Island of Lamö, near Brevig, Norway. Formed from the alteration of elæolite. It may be identical with the ozarkite of Shepard (Dana Min., p. 426).

REDONDITE, Shepard, Am. J. Sci., II., xlvii., 428, l., 96.—Appendix I., p. 13.

RESIN, Min. p. 739 et seq.—Samland, Brüsterort, *Spirgatis*, Ber. Ak. München, 1871, 172.

Valley of the Arno. *Guareschi*, Boll. Com. Geol. d'Italia, 1871, 70. See BOMBICCITE.

Alaska, p. 88; Mesen, p. 90, *Chydenius*, Œfv. Finsk. Vet. Soc., xiii., 71, 1870.

Helbing has described a new resin from a quarry at Enzenau, near Heilbrunn. An analysis gave C 75·01, H 9·51, O 1·37, FeS_2 14·11 = 100·00. The part soluble in ether (19 p. c.) has the composition, $C_{10}H_{16}O_2$; 9 p. c., soluble in ether and hot alcohol, has the composition $C_{10}H_{16}O$; and 72 p. c., insoluble, gives $C_{40}H_{64}$.—Ann. Ch. Pharm., clxxii., 297 1874.

REISSITE, *Hessenberg*, Min. Not., ix., 22.—Appendix I., 14.

RESTORMELITE. *Church*, J. Ch. Soc., II., viii., 166.—Appendix I., p. 13.

346 A. Resanite, *Cleve*, Ak. H. Stockh., ix., No. 12 (Nov., 1870). Geol. West India Islands, p. 28. A hydrous silicate of copper and iron, of an olive-green color, uncrystalline. G. = 2·06. Analysis, Fiebelkorn, l. c.,

$\ddot{\text{Si}}$	$\dot{\text{Cu}}$	$\dddot{\overline{\text{Fe}}}$	$\dot{\text{H}}$ (loss at 100°)	$\dot{\text{H}}$ (ignition)
35·08	23·18	9·91	23·15	8·53 = 99·85

If the iron is protoxide it gives the formula $\dot{\text{R}}^2\ddot{\text{Si}}^3 + 9$ aq. It is easily decomposed by HCl. Found with malachite and chrysocolla, at Puerto Rico (Luquillo), West Indies, and named from Don Pedro Resano.

Retinite, Min. p. 739.—Chydenius, Œfv. Finsk. Vet. Soc., xiii., 92, 1870–71.

Retzbanyite, Min. p. 100.—Equivalent with cosalite, Frenzel, Jahrb. Min., 1874, 681.

577. Rhagite, Weisbach (Abh. Berg. u. Hüttenwesens), Jahrb Min., 1874, 302. Winkler, J. pr. Ch., II., x., p. 190, 1874.

In crystalline aggregates, spherical or mammillary (isometric), smooth on the surface. H. = 5. G. = 6·82. Color yellowish-green, sometimes wax-yellow. Lustre wax-like. On the edges translucent; brittle; fracture dense and incompletely conchoidal.

Analysis, Winkler (l. c.)

$\dddot{\overline{\text{Bi}}}$	$\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\text{As}}}$	$\dddot{\overline{\text{Fe}}}$, $\dddot{\overline{\text{Al}}}$	$\dot{\text{Co}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$	gangue
72·76	14·20	1·62	1·47	0·50	4·62	3·26 = 98·43

giving the formula, $\dddot{\overline{\text{Bi}}}^5\,\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\text{As}}}^2\,\dot{\text{H}}^8$. It is related to atelestite.

Easily soluble in hydrochloric acid, with difficulty in nitric acid. In the matrass decrepitates, and crumbles to a yellow powder, giving off its water; on charcoal fusible.

Occurs on bismutite and quarz, accompanied by walpurgite, at the "Weisser Hirsch" mine, near Schneeberg, Saxony.

Rhodite, Adam, Tableau Min., 1869, p. 83.—Rhodium-gold described by del Rio. Dana Min. p. 4.

Rhodochrosite, Min. p. 691.—Franklin, N. J., anal., *Roepper*, Am. J. Sci., II., l., 37, 1870; see also Am. J. Sci., III., iv., 146, 1872. See stirlingite.

Rionite, Jahrb. Min., 1870, 590.—Appendix I., p. 14.

Ripidolite, Min. p. 497.—Kotschubeite, analyses, *Kokscharow*, Min. Russl., v. 369; vi., 92.

Massaschlucht, anal., *v. Fellenberg*, Jahrb. Min., 1868, 746.

Monte Pisani, etc., anal. (Gherardi), *Achiardi*, Boll. Com. Geol. Ital., 1871, 156.

Brewster, N. Y., anal., *Breidenbaugh*, Am. J. Sci., III., vi., 208, 1873.

Zillerthal, anal., Tsch. Min. Mitth., 1874, 244.

Rittingerite, Min. p. 94.—Joachimsthal, consists essentially of arsenic, selenium, and silver, monoclinic ($C = 90°\,34'$), *Schrauf*, Ber. Ak. Wien, lxv., 227, 1872.

507. A. Rivotite, *Ducloux*, C. R., lxxviii., p. 1471, 1874.

Amorphous, compact, with a stony look. Fracture uneven. Opaque. Color yellowish green to grayish-green. Streak grayish-green.

H. = 3·5–4. G. = 3·55–3·62. Fragile, breaking into pieces at the blow of a hammer.

Analysis, Ducloux (l. c.)

$\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\text{Sb}}}$	$\dot{\text{Ag}}$	$\dot{\text{Cu}}$	$\ddot{\text{C}}$	$\dot{\text{Ca}}$		
42·00	1·18	39·50	21·00	tr	=	103·68

Ducloux gives the formula $\overset{\cdot\cdot\cdot\cdot\cdot}{\overline{\text{Sb}}}_2 + 4\left.\begin{matrix}\dot{\text{Cu}}\\ \dot{\text{Ag}}\end{matrix}\right\}\ddot{\text{C}}$, urging that the antimony is present in the condition of antimonic acid.

Decrepitates on heating, colors the flame green. On charcoal alone, in reducing flame, leaves a metallic globule with no odor of arsenic nor fumes of antimony. In the closed tube gives off carbonic acid and becomes black. Gives no reaction for sulphur. With the fluxes gives a copper reaction. Treated with hydrochloric acid in the cold gives off carbonic acid, but dissolves only in part.

Occurs in small irregular masses disseminated through a yellowish-white limestone, on the west side of the Sierra del Cadi, province of Lerida.

Named in honor of M. Prof. Rivot of the School of Mines, Paris.

RŒPPERITE. *Rœpper*, Am. J. Sci., II., l., 35.—*Brush*, Appendix I., p. 18.

Kenngott (Jahrb. Min., 1872, 188) has proposed to give the name *rœpperite* to the manganese dolomite, analyzed by Rœpper (l. c.), and the name *stirlingite* to the iron-manganese-zinc-chrysolite. The latter name cannot stand as it has already been given to the mineral most characteristic of the locality (Franklin, N. Y.), that is, the red oxyd of zinc (zincite, *Dana*, but see Min. 5th ed., 5th sub. ed., p. 135), Alger. Min., p. 565, 1844, by him incorrectly written sterlingite. Moreover the other mineral being only a sub-variety does not deserve a name. Almost simultaneously with the note of Kenngott, Brush gave the name rœpperite to the new chrysolite of Rœpper, and there is no question but that this name should be received; it may be added that it is already accepted by *Groth*, Tabellarische Uebersicht der Mineralien, etc., p. 52, 1874.

RŒSSLERITE, Min. p. 556.—Joachimsthal, *Tschermak*, Ber. Ak. Wien, lvi., 828, 1867.

ROMEITE, Min. 547.—Composition, *Kenngott*, Jahrb. Min., 1870, 999.

ROSELITE, Min p. 560.—This very rare mineral has been recently rediscovered at the Daniel Mine near Schneeberg. Schrauf (Tsch. Min. Mitth., 1874, 137) has investigated it thoroughly, and proved that it is beyond doubt an independent species. According to him its crystalline form is triclinic, a (vert.) : b : c = 1·4468 : 1 : 2·2046. The fundamental angles are: $\xi = 91° 0'$, $\eta = 89° 26'$. $\zeta = 90° 40'$. The habit of the crystals is quite varied, but they are especially characterized by their tendency to the formation of twins. All the crystals investigated by Schrauf proved to be twins, in many cases of the most complex nature. But without figures any description of them would be unintelligible. H. = 3·5. G. = 3·585, Rappold (on crystals, 0·08 gr.); 3·506 Daniel (crystals, 0·04 gr.); 3·738 Rappold (massive and perhaps not perfectly pure), Schrauf. G. = 3·46. Weisbach (Jahrb. Min., 1874, 871).

Analyses, 1. and 2. Schrauf (l. c.); 3. Winkler, J. pr. Ch., II., x., 191, 1874.

		$\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}\mathrm{s}}_2$	$\dot{\mathrm{C}}\mathrm{o}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{H}}$		
1.	Daniel Mine.	50·9	(12·1)	21·9	4·3	10·8	=100·00	Schrauf.
2	Rappold Mine.	49·6	(15·9)	19·2	4·8	10·5	=100·00	Schrauf.
3.	Daniel Mine.	49·96	12·45	23·72	4·67	9·69	=100·49	Winkler.

Schrauf writes the formula $\dot{\mathrm{R}}^3\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}\mathrm{s}}_2 + 3\dot{\mathrm{H}}$ or more exactly $7\dot{\mathrm{C}}\mathrm{a}, 2\dot{\mathrm{M}}\mathrm{g}3\dot{\mathrm{C}}\mathrm{o}, 8\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}\mathrm{s}}_2, 10\dot{\mathrm{H}}$, (for crystals from the Daniel Mine), and $6\dot{\mathrm{C}}\mathrm{a}, 2\dot{\mathrm{M}}\mathrm{g}, 4\dot{\mathrm{C}}\mathrm{o}, 8\overset{\cdot\cdot\cdot\cdot\cdot}{\bar{\mathrm{A}}\mathrm{s}}, 10\dot{\mathrm{H}}$ for those from the Rappold mine. The Daniel crystals have a lighter color, corresponding to the smaller percentage of cobalt, and greater amount of lime.

When heated at 100° C., the crystals break into fragments, and take a dark-blue color, but resume their red color on cooling.

ROSTHORNITE, Höfer, Jahrb. Min., 1871, 561.—Appendix I., p. 14.

SCACCHITE, Adam, Tableau Min., 1869, p. 70.—A chlorid of manganese, supposed by Scacchi to occur at Vesuvius. See Dana, Min., p. 123.

112 B. Schirmerite, Genth, Am. Phil. Soc. Philad., xiv., 230, Aug. 21st, 1874.
Massive, finely granular, disseminated through quartz; no cleavage observed. Fracture uneven; soft; brittle. G. = 6·737. Color lead-gray, inclining to iron-black. Lustre metallic. B.B. fuses easily, and gives the reactions for bismuth, lead, silver and sulphur.
Analyses, 1. (1 p. c. quartz deducted). 2. (1·07 p. c. deducted).

	Pb	Ag	Bi	Zn	Fe	S
1.	12·69	22·82	46·91	0·08	0·03	14·41 = 96·94
2.	12·76	24·75	(47·27)	0·18	0·07	15·02 = 100·00

Atomic ratio for Pb : Ag : Bi : S = 1 : 4 : 4 : 9 nearly, corresponding to PbS, $2Ag_2S$, $2Bi_2S_3$. It is allied to and closely resembles cosalite.
Occurs with other tellurium minerals at the Red Cloud mine, Colorado.
Named from J. F. L. Schirmer, Esq.

Schirmerite, Endlich, Engineering and Mining J., Aug. 29th, 1874.
Color bright lead-gray with tinge of purple. H. = 2–2·5.
Composition (according to analyses not published), (AuFe)Te + 3AgTe.
B.B. magnetic before the oxydizing flame. Occurs massive, disseminated through the ore, giving it a dark-gray color; also in thin streaks. Red Cloud mine, Colorado.
Dr. Genth (l. c.) asserts that this so-called new species "is nothing else but a mixture of petzite either with pyrite, or perhaps with a tellurid of iron," and "is based upon a partial examination of a mixture," and therefore "is not entitled to a name."

SCHREIBERSITE, Min. p. 61.—In meteoric irons, *Meunier*, Ann. Ch. Phys., IV., xvii., 43, 1869.

755 A. Schröckeringite, *Schrauf*, Tsch. Min. Mitth., 1873, p. 137.
Occurs at Joachimsthal on uraninite, in small, six-sided tabular crystals; $i\text{-}\breve{i} \wedge I = 121\frac{1}{2}°$. Prismatic, one bisectrix being normal to $i\text{-}\breve{i}$. Color greenish to yellow. It is a hydrous oxy-carbonate of uranium, containing only traces of $\bar{S}$. Loss by ignition ($\dot{H}$ and $\ddot{C}$) = 36·7 Contains also a little lime.

SCOLECITE, Min. p. 428.—Chili, anal., Domeyko, 2d App. Min. Chili, p. 47, 1867.
Composition, *Rammelsberg*, ZS. G. Ges., xxi., 96, 1868; *Kenngott*, Jahrb. Min., p. 1870, 998.
Lunddörrsfjäll, anal., *Igelström*, Jahrb. Min., 1871, 361.
(Poohnahlite), India, anal., *Haughton*, J. R. Geol. Soc. Dublin, II., 1868, 114; *Petersen*, Jahrb. Min., 1873, 852.

388 A. Seebachite, *Bauer*, ZS. G. Ges., xxiv., p. 391; xxv., p. 351, and *Rammelsberg*, xxv., p. 96.

Bauer makes the mineral described as herschelite by Ulrich (Geol. and Min. of Victoria, p. 61-66) a new species, under the name of seebachite, and in this he is supported by Rammelsberg.

Analyses (l. c.), 1. Kerl; 2. Lepsius.

	$\ddot{\mathrm{Si}}$	$\bar{\mathrm{A}}\mathrm{l}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{N}}\mathrm{a}_2$	$\dot{\mathrm{K}}_2$	$\dot{\mathrm{H}}_2$
1.	43·7	21·8	8·5	3·5	tr	22·7 = 99·7
2.	44·77	22·10	7·51	3·18	—	22·07 = 99·63

It occurs with phillipsite in the basalt quarries of Richmond near Melbourne, and according to v. Lang (Phil. Mag., IV., xxviii, p. 506) is identical crystallographically with herschelite from Sicily. (See also Jahrb. Min., 1874, 522.)

In sphærosiderite, *Schnorr*, Jahrb. Min., 1874, 631.

83 A. Spathiopyrite. Sandberger, Der rhombische Arsenkobalt, Jahrb. Min., 1868, 410; 1873, p. 59. Sitzsb. Ak. München, 1873, 135.

Orthorhombic, in rounded or complex crystals, combinations of *I* and m-$\bar{\imath}$; also, more rarely, in simple crystals, showing the same planes. Macrodome planes well polished, prismatic planes dull. Angles apparently very near those of leucopyrite, Dana.

H. = 4·5, G. = 6·7. Color tin-white on the fresh fracture, but changes rapidly to a dark steel-gray.

Analysis v. Gerichten (l. c.).

As	S	Co	Cu	Fe
61·46	2·37	14·97	4·22	16·47 = 99·49

Atomic ratio for Co, Fe, Cu to As,S = 2 : 3. It contains no nickel.

Found on smaltite (Speiskobalt), or filling cavities in it, in the cobalt veins at Bieber in Hessen.

SPHENE. See TITANITE.

Sterlingite. See DAMOURITE.

STETEFELDTITE, Min. p. 188.—An antimonite of copper, resembling stetefeldtite, has been described by Domeyko as occurring at the Potochi copper mine, near Huancavelica, Peru. It is amorphous, compact. Fracture smooth or uneven, in parts coarsely granular. Color black or greenish black. Streak yellowish-green. Lustre weakly resinous. An analysis on the purest material obtainable (though still mixed with some sub-sulphate of copper), gave SbO_5 32·93, CuO 32·27, Fe_2O_3 11·14, ZnO 0·50, SO_3 1·00, H_2O (loss at low redness), 18·58, insoluble, 1·57 = 96·94. B.B. infusible. Dissolves readily in hydrochloric acid. Domeyko regards the mineral as probably having come from the decomposition of chalcostibite, an analysis of which he adds. 3d Appendix Min. Chili, 1871.

587. Stibioferrite. E. Goldsmith, Proc. Ac. Philad., 1873, p. 366.

Generally amorphous. Crystals observed in a cavity and supposed to be the same substance (no reason given) were orthorhombic showing planes $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, *I* and *O*, approximate measurement gave $I\ (i\text{-}\bar{i})\ I = 100°\ 8'$.

H. =4. G. =3·598. Lustre slightly resinous. Color (cryst.) faint yellow; yellow to brownish-yellow (amorphous). Streak dull yellow, brittle, fracture uneven chonchoidal.

Analysis (l. c.).

$\overset{\cdot\cdot}{\overline{\text{Sb}}}$	$\overline{\text{Fe}}$	$\dot{\text{H}}$	$\ddot{\text{Si}}$	loss		
42·96	3·85	15·26	8·84	1·09	=	100·00

Deducting the iron we obtain as the oxygen ratio $\overset{\cdot\cdot}{\overline{\text{Sb}}} : \overline{\text{Fe}} : \dot{\text{H}}$, 1·1 : 1 : 1·4 or 1 : 1 : 1½= $2(\overset{\cdot\cdot}{\overline{\text{Sb}}} + \overline{\text{Fe}}) + 3\dot{\text{H}}$. B. B. gives reaction for antimony and iron. Soluble in hydrochloric acid.

Occurs as a coating, sometimes ¼ inch thick, on stibnite from Santa Clara Co., Cal.

STIBIOTRIARGENTITE, *Stibiohexargentite*, *Petersen*.—Appendix I., p. 15.

454. A. Strigovite, Becker and Websky, Jahrb. Min., 1869, p. 236. Websky, ZS. G. Ges., xxv., 388, 1873.

In minute crystals, showing hexagonal prisms under the microscope; sometimes in balls of aggregated crystals, and shown by the behavior in polarized light to belong to the hexagonal system. H.=1. G=3·144. Color dark-green (on alteration changing to brown). Streak green to grayish-green. Analyses: 1. Becker l. c. 2. Websky (G. =2·788), Jahrb. Min., 1869, 236. 3. Websky, Jahrb. Min., 1873, 391.

	$\ddot{\text{Si}}$	$\overline{\text{Al}}$	$\dot{\text{Fe}}$	$\overline{\text{Fe}}$	$\dot{\text{Mn}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{H}}$	loss	
1.	32·62	16·66	16·74	16·04	——	3·16	2·02	12·37	——	= 99·61
2.	32·60	14·08	12·47	21·94	——	3·82	——	14·81	0·28	=100·00
3.	28·43	16·60	11·43	26·21	7·26	0·36	0.36	9·31	——	= 99·96

Analyses 1. and 2. were made on material which had suffered some alteration, so that 3. alone expresses the correct composition. Oxygen ratio $\dot{\text{R}} : \overline{\text{R}} : \ddot{\text{Si}} : \dot{\text{H}}$=(approx.) 3 : 3 : 4 : 2. Easily decomposed by acid with the separation of silica in powder. In closed tube gives off water. B. B. fuses with difficulty to a black glass without coloring the flame.

Occurs as a fine coating over the minerals in druses or cavities in the granite west and north-west of Striegau in Silesia

STROMEYERITE, Min. p. 54.—Chili, anal., Domeyko, 2d App. Min. Chili, p. 35, 1867. Argentine Republic, anal., Siewert, Tsch. Min. Mitth., 1873, 251.

SYLVITE, Min. p. 111.—Stassfurt, cryst. Huyssen, ZS. G. Ges., xx., 460, 1868. Kalusz, cryst., Tschermak, Ber. Ak. Wien, lxiii., 308, 1871.

656. A. **Syngenite**, *v. Zepharovich*, Lotos, p. 137, p. 213, June, 1872; Ber. Ak. Wien, lxvii., p. 128, 1873. Kaluszite, *Rumpf*, Tsch. Min. Mitth., 1872, 117, 197; 1873, 147.

Monoclinic, *a* (vert.) : *b* (clinodiag.) : *c*=0·8738 : 1·3699 : 1 or ·63786 : 1 : 72998. *C*=76° 0′. Observed planes *O*, *i*-í, *i*-ì −1-í, −$\frac{2}{3}$-í, 1-í, 2-í, *I*, *i*-8, *i*-6, *i*-4, *i*-3, *i*-2, *i*-$\frac{3}{2}$, *i*-2̀, 1-ì, −1, −4·4, 1, 2, 2-2. *I* ∧ *I* = 73° 55′ (over *i*-í). *O* ∧ 1-ì=139° 42′. *O* ∧ −1-í = 151° 49′. *O* ∧ 1-í =143° 48′. *O* ∧ −1=137° 44′; *i*-í ∧ −1 = 124° 19′, *i*-ì ∧ −1=122° 55′.

In generally small tabular crystals, elongated in the direction of the vertical axis, the plane *i*-í always predominates, and is striated vertically.

Cleavage *I* perfect, also *i*-í. In other directions fracture conchoidal. Plane of optic axes parallel to the orthodiagonal section, acute bisectrix makes an angle of 2° 46′ with *i*-í. Optic-axial angle apparent in air—red=41° 35′, blue=46° 22′; actual angle, red=26·31, blue, 29· 24′ (Vrba). Index of refraction 1·55 (Vrba). Double refraction negative. Dispersion of axes $\rho < \upsilon$.

H.=2·5. G.=2·603 (mean), 2·252 (Rumpf, l. c.). Colorless or milky-white.

Analyses, 1. Ullik (mean of four closely agreeing analyses, in one of which was also found 1·42 p. c. NaCl), Tsch. Min. Mitth., 1872, 120; 2. Völker, Ber. Ak. Wien, lxvi., 197, 1872.

	$\dot{\text{C}}\text{a}$	$\dot{\text{K}}$	$\dddot{\bar{\text{S}}}$	$\dot{\text{H}}$		
1.	16·88	28·55	48·45	5·47		= 99.35
2.	16.97	28·03	49·04	5·85	(also 0·46 $\dot{\text{M}}\text{g}$.)	= 99·89

These give the formula $\dot{\text{C}}\text{a}\dddot{\bar{\text{S}}}$, $\dot{\text{K}}\dddot{\bar{\text{S}}}+\dot{\text{H}}$, or the same with the artificial salt, which Zepharovich shows to be also monoclinic (ib., p. 139). In form the syngenite is closely related to gypsum, particularly in the angles of the prismatic zone.

In the flame of a Bunsen gas-burner becomes milky, colors the flame violet, and melts easily to a colorless (on cooling white) bead, with a crystalline granular texture. In matrass gives off water, decrepitating violently. Easily attacked by water, dissolving in part with the separation of sulphate of lime. Vrba found that one part of syngenite dissolved in 400 pts. of water. Found in cavities in halite at Kalusz, East Galicia. Name derived from συγγενής (related), alluding to its close relation to polyhalite.

TELLURATE OF COPPER AND LEAD, discovered by Mr. Knabe, at the Iron Rod Mine, Silver Star District, Montana, occurring in fissures in the rock. At the Green Campbell Mine it is found as a thin coating upon the selvage of the foot wall. Proved to contain copper, lead, and telluric acid. The sample sent to Dr. Genth consisted of an apparently uniform siskine-green powder. He speaks (priv. contrib.) of proposing to investigate the material further, and, if its supposed character is sustained, will give it a distinctive name. *Genth*, Am. Phil. Soc. Philad., xiv., 229, 1874.

Tocornalite, Domeyko, 2d Append. Min. Chili, p. 41, 1867.

Amorphous, structure granular. Color a pale-yellow, by the action of the air it grows darker, and passes to a grayish-green, and finally to a grayish-black and black. Soft, easily reduced to a powder. Streak yellow.

Composition Ag I + Hg^2I. An analysis gave Ag 33·80, Hg 3·90. I 41·77, siliceous residue 16·65 = 96·12. The loss is due to some water belonging with the residue, and probably some iodine.

In the closed tube gives off first water, then a yellow ring, followed by a mixed sublimate (mercurial), and finally a red ring. With carbonate of soda in the matrass gives only pure mercury. Decomposed by nitric acid. From the mines of Chañarcillo, Chili.

TRÖGERITE, *Weisbach*, Jahrb. Min., 1871, 870; 1873, 315.—Appendix I., p. 16.

Winkler has analyzed the trögerite of Weisbach with the following results; Analyses 1 3 p. c. impurities deducted. 2. 4½ p. c. deducted. 3. on pure material.

	$\dddot{\overline{\mathrm{As}}}$	$\overline{\mathrm{U}}$	$\dot{\mathrm{H}}$
1.	18·48	63·44	18·08 = 100·00
2.	18·83	62·42	18·75 = 100·00
3.	19·64	63·76	14·81 = 98·21

which correspond to the formula $3\overline{\mathrm{U}}\,\dddot{\overline{\mathrm{As}}} + 12\dot{\mathrm{H}}$.

On heating it gives off water, and takes a golden-brown color, but resumes a yellow on cooling. J. pr. Ch., II., vii., 6. 1873.

TROILITE, Min. p. 57.—*Meunier* concludes that the composition of troilite is (FeNi)'Si (not FeS), Ann. Ch. Phys., IV., xvii., 36, 1869; C. R., lxviii., 763, 1874. *Rammelsberg*, Abh. Ak. Berlin, 1870, 84).

TSCHEFFKINITE, Min. p. 387.—Composition, *Hermann*, J. pr. Ch., cvi., 332, 368.

314 A. Tschermakite, *v. Kobell*, J. pr. Chem., II., viii., 411, 1873.

Massive, cleavage on two surfaces, making an angle of 94°. Striations on face of better cleavage. H. 6. G. 2·64. Phosphorescent. Color grayish to white. Translucent. Lustre vitreous. Analysis, l. c.;

$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Na}}$($\dot{\mathrm{K}}$ tr)	$\dot{\mathrm{H}}$
66·57	15·80	8·00	6·80	2·70 = 99·87

This would give the formula $3\dot{\mathrm{R}}\,\ddot{\mathrm{Si}} + \bar{\mathrm{Al}}\,\ddot{\mathrm{Si}}_3$, or that of a magnesian oligoclase. It occurs with kjerulfine and quartz at Bamle, Norway.

G. W. Hawes (Am. J. Sci., III., vii., 579, 1874) has analyzed a mineral from the above locality, and labelled tschermakite, with the following results: G. = 2·67.

$\ddot{\mathrm{Si}}$	$\bar{\mathrm{Al}}$	$\bar{\mathrm{Fe}}$	$\dot{\mathrm{Ca}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{K}}$	$\dot{\mathrm{Na}}$	ign.
66·04	20·37	0·29	1·29	1·10	0·21	9·91	0·96 = 100·17

This gives a composition very near that of albite.

The mineral agreed in all its physical characters with the description of tschermakite, but was almost destitute of magnesia, which suggests the idea that the material analyzed by v. Kobell may have been impure.

Des Cloizeaux has since (C. R., lxxx., Feb. 8, 1875) found that the so-called tschermakite from Bamle is identical with albite in optical properties. He quotes, moreover, the following analysis by Pisani: $\ddot{\mathrm{Si}}$ 66·37, $\bar{\mathrm{Al}}$ 22·70, $\dot{\mathrm{Ca}}$ 1·40, $\dot{\mathrm{Mg}}$ 0·95, $\dot{\mathrm{Na}}$ 9·70, $\dot{\mathrm{H}}$ 0·70 = 101·82 G. = 2·60. This gives the oxygen ratio for $\dot{\mathrm{R}} : \bar{\mathrm{R}} : \ddot{\mathrm{Si}}$ = 1 : 3 : 11, or nearly that of albite.

URANINITE, Min. p. 154.—Colorado, Am. J. Sci., III., v., 386, 1873.

URANOPHANE, Min. p. 805.—Discussion of composition, = a thomsonite in which ½ alumina is replaced by uranium, *Websky*, ZS. G. Ges., xxi., 92, 1869; see also *Weisbach*, Jahrb. Min., 1873, 326.

624 A. Uranosphærite. Weisbach, Jahrb. Min., 1873, 315; Winkler, J. pr. Chem., II., vii., 5.

In half-globular aggregated forms, sometimes with a dull, or slightly lustrous surface, sometimes rough and drusy, showing under the miscroscope that they are made up of minute acutely-terminated crystals. Structure concentric, also radiated. H. = 2-3, G. = 5·36. Color orange-yellow, brick-red (Winkler). Lustre greasy. Streak yellow.

Analyses, Winkler, l. c., 1. impurities (11 p. c.) deducted, 2. perfectly pure material.

	$\ddot{\bar{U}}$	$\dddot{\bar{Bi}}$	$\dot{H}$
1.	50·32	44·13	5·56
2.	50·88	44·34	4·75

These give the formula $\dddot{\bar{Bi}}\ 2\ddot{\bar{U}} + 3\dot{H}$.

Decrepitates on heating, and falls to pieces to a mass of crystalline needles, with silky lustre, homogeneous and of brown color.

Occurs with other related uranium minerals at the mine Weisser Hirsch, near Schneeberg. Saxony.

573 C. **Uranospinite.** Weisbach, Jahrb. Min., 1873, 315; Winkler, J. pr. Ch. II., vii., 11.

Orthorhombic. In scale-like crystals, with quadratic or rectangular outlines. Cleavage perfect, parallel to the planes of the scales. H. = 2-3. G. = 3·45. Color siskine-green.

Analysis, Winkler (l. c.);

$\overset{.....}{\bar{As}}$	$\ddot{\bar{U}}$	$\dot{Ca}$	$\dot{H}$
19·37	59·18	5·47	16·29 = 100·31

which corresponds approximately with the formula $\dot{Ca}$, $\ddot{\bar{U}}\ \overset{.....}{\bar{As}} + 8\dot{H}$.

Weisbach regards it as an arsenate corresponding to autunite. Winkler succeeded in making uranospinite artificially with the following composition: $\overset{.....}{\bar{As}}$ 23·01, $\ddot{\bar{U}}$ 59·01, $\dot{Ca}$ 5·62, $\dot{H}$ 14·27 = 101·91.

Found with other related uranium minerals, at the mine Weisser Hirsch, near Schneeberg, Saxony.

URANOTIL, *Boricky*, Jahrb. Min., 1870, 780; see also Jahrb. Min., 1873, 296, 316.—Appendix I., p. 16.

445 D. **Vaalite,** *Maskelyne* and *Flight*, Q. J. G. Soc., xxx., 409, Nov., 1874.

Monoclinic. $C = 76°\ 30'$. Occurring in hexagonal prisms; $I \wedge I = 60°\ 10'$. $I \wedge O = 96°\ 40'$ (calc. $= 96°\ 41'$).

Cleavage *O* easy, *I* much less so. Normal to *O* coincident, or very nearly so, with the mean line of the optic axes; optic-axial angle very small; double-refraction negative.

Color drap, in spots fine blue.

Analysis (l. c.)

$\dddot{Si}$	$\dddot{\bar{Al}}$	$\dddot{\bar{Fe}}$	$\dot{Mg}$	$\dot{Na}$	$\dot{H}$	$\ddot{C}$	$\dddot{\bar{Cr}}$
40·83	9·80	6·84	31·34	0.67	9·72	tr	tr = 99·20.

giving the formula $\dddot{\bar{R}}\ \dddot{Si} + 2\ (3\dot{Mg}, 2\dddot{Si}, 2\dot{H})$. Oxygen ratio for $\dot{R} : \dddot{\bar{R}} : \dddot{Si} : \dot{H} = 6 : 3 : 10 : 4$. Expands on heating on a platinum foil to six times original size, in powder no expansion at all. Loses no water at 100 C. Occurs in an altered bronzitic rock from the diamond-diggings, called Du Toit's Pan, So. Africa.

Valleriite, Blomstrand, Œfv. K. Akad. Stockholm, xxvii., p. 19, 1870.

Massive, without a trace of crystalline texture. Color very like that of pyrrhotite. Lustre perfectly metallic; fracture uneven. Resembling graphite in its unusual softness (yields to the nail, and can be cut with a knife), and in its property of leaving a dark streak, when scratched on paper. G. = 3·14.

Analyses (l. c.) in part from different samples, (neglecting a small insoluble portion).

	Fe	Al	Cu	Mg	Ca	Na	K	S	$\dot{H}$
1.	29·32		17·00	6·26	——	0·59	0·31	22·20	——
2.	——	——	——	——	——	——	——	——	10·77
3.	——	——	18·66	——	——	——	——	22·73	——
4.	27·18	2·29	18·91	4·97	——	0·31	0·16	22·68	——
5.	25·50	3·18	16·51	7·80	0·18	——	——	——	——
Mean	26·34	2·73	17·77	6·34	0·18	0·45	0·23	22·54	10·77 = 87·35

The variation in Cu and Mg in the analyses is regarded by Blomstrand as showing a possible variation in the composition of the species. Regarding all the Cu as combined as $Cu\bar{S}$

and giving the remainder of the sulphur to the iron (FeS_2), and calculating the other metals as oxyds, we obtain:

CuS	FeS^3	$\overline{\text{Fe}}$	$\overline{\text{Al}}$	$\dot{\text{Mg}}$	$\dot{\text{Ca}}$	$\dot{\text{Na}}$	$\dot{\text{K}}$	$\dot{\text{H}}$
26·74	29·40	15·01	5·14	10·57	0·25	0·61	0·27	10·77=98·76

Giving essentially the formula $2CuS, FeS^3+2\dot{\text{Mg}}\overline{\text{Fe}}+4\dot{\text{H}}$.

B. B., loses its lustre and becomes darker. In the matrass gives off water and a slight coating of sulphur. The water is strongly combined, and is given off only at a full red heat.

Very rare; occurs in small (large as hazelnuts) fragments in a dark-greenish limestone, which is much mixed with mica and other minerals, at the Aurora Mine, Nya-Kopparberg, Sweden.

Named for the Swedish mineralogist Vallerius. [A very doubtful compound.]

VANADINITE, Min. p. 610.—So. Africa, anal., *Maskelyne* and *Flight*, J. Ch. Soc., II., x., 1053, 1872.

The researches of Roscoe have shown that vanadic acid is V_2O_5, not V_2O_3, which explains the similarity of vanadinite crystals to those of pyromorphite, Phil. Trans., 1869, 1870.

WACKENRODITE, Adam, Tableau Min., 1869, p. 76. A variety of wad containing 12·22 p. c. $\dot{\text{Pb}}$; see Dana, Min., p. 182, anal. 6.

WAD, Min. p. 181.—Groroilite, district Jacala, Mexico, *M. Barcena*, Naturaleza, iii. 186, 1874.

WAGNERITE, Min. p. 538.—Anal., showing the presence of 4 p. c. alkalies, *v. Kobell*, J. pr. Ch., II., vii., 275, 1873.

WALPURGITE, Weisbach, Jahrb. Min., 1871, 870; 1873, 315; in Appendix I., p. 16
Winkler has analyzed the walpurgite of Weisbach, with the following results:

$\ddot{\bar{\mathrm{A}}}\mathrm{s}$	$\bar{\mathrm{U}}$	$\bar{\mathrm{B}}\mathrm{i}$	$\dot{\mathrm{H}}$
11·88	20·29	61·43	4·32 = 97·92
13·03	20·54	59·34	4·65 = 97·56

These correspond to the formula $5\bar{\mathrm{B}}\mathrm{i}, \ddot{\bar{\mathrm{A}}}\mathrm{s} + 3\bar{\mathrm{U}}\,\ddot{\bar{\mathrm{A}}}\mathrm{s} + 10\dot{\mathrm{H}}$.

In a red-heat the crystals take a brown color, which passes into an orange-yellow on cooling. No decrepitation on heating takes place, and no change of form. Decomposed by nitric acid, leaving a white residue of arsenate of bismuth, which goes into solution on the addition of hydrochloric acid. J. pr. Ch., II., vii., p. 6, 1873.

520 C. Wapplerite, *Frenzel*, Tsch. Min. Mitth., 1874, 279.

Triclinic. Crystals minute and highly modified, resembling augite or wolframite in habit. Also in incrustations sometimes crystalline, or globular, sometimes glassy, with a reniform surface. Cleavage clinodiagonal. H. 2-2·5. G. 2·48. Color white. Translucent, the crystals colorless. Lustre strongly vitreous. [Crystallographic determination by Schrauf, (priv. contrib., dated Vienna, March 20th, 1875). Triclinic. a (vert.) : b : c = 0·29037 : 1 : 1·11002. $\xi = 90° 13' 55''$; $\eta = 95° 20'$; $\zeta = 90° 10' 35''$. Observed planes, *i*-ĭ, *i*-2̆, *i*-2̆′, *I*, *I*′, *i*-ī, 1-ĭ, 1-ĭ′, 3-ĭ, 3-ĭ′, 10-ĭ, −2-2̆, 2-2̆, −2-2′, 2-2′, −4-4̆, 4-4̆, −4-4̆′ 4-4̆′, −3-3/2, −3-3/2′, −5-5/4, −5-5/4′, −7-7/4, −7-7/4′. *i*-ĭ ∧ *I* = 132° 0′; *i*-ĭ ∧ *I*′ = 131° 40½′; *i*-ĭ ∧ 1-ĭ = 104° 50′; *i*-ĭ ∧ −2-2′ = 123° 14′.]

The crystals are characterized by prevalence of zones, by which means nearly all of the planes could be determined.

Wapplerite undergoes alteration, by taking up one equivalent of water, forming white opaque pseudomorphs which have been described as *rœsslerite* (Dana, Min., p. 556).

Analyses, Frenzel (l. c.).

$\ddot{\bar{\mathrm{A}}}\mathrm{s}$	$\dot{\mathrm{C}}\mathrm{a}$	$\dot{\mathrm{M}}\mathrm{g}$	$\dot{\mathrm{H}}$
47·70	14·15	8·29	29·40 = 99·58
47·69	15·60	7·35	29·49 = 100·13

These give for the composition $2\dot{\mathrm{C}}\mathrm{a}\,\ddot{\bar{\mathrm{A}}}\mathrm{s} + 8\dot{\mathrm{H}}$, where some lime is replaced by magnesia. Of the water 5 atoms go off at 100° C., the remainder at 360°.

Found with pharmacolite at Joachimsthal.

WARRINGTONITE, Min. p. 664.—See *brochantite*. Domeyko, 2d Appendix, Min. Chili, p. 23, 1867.

WERNERITE, Min. p. 319.—Bucks Co., Penn., anal., *Leeds*, Am. J. Sci., III., viii., 433, 1874.

WESTANITE, *Blomstrand*, J. pr. Ch., cv., 341.—Appendix I., p. 16.

813 B. Wheelerite. O. Loew, Am. J. Sci., III., vii., p. 571.

A resin, yellowish in color, found in the Cretaceous beds of northern New Mexico, filling the fissures of the lignite, or interstratified in thin layers in it. Most abundantly observed in the vicinity of Nacimiento.

Two analyses gave Loew (l. c.)

	C	H
1.	73·07	7·95
2.	72·87	7·88

which agree closely with the formula $n\,(C_5H_6O)$, where n is probably 5 or 6.

Soluble in ether, less so in bisulphide of carbon. In concentrated sulphuric acid dissolves, producing a dark-brown solution, from which it is precipitated by water. In alcohol the principal portion is readily dissolved, while a small part remains insoluble. The hot alcoholic extract of the resin deposits, on cooling, a few yellow flocculi. The solution, on evaporation, gives a yellowish resin very brittle, and becoming strongly electric on friction. It melts at 154° C.

Named for Lieut. G. M. Wheeler, U. S. Army.

WHEWELLITE, Min. p. 718.—Cryst., *Schmid*, Pogg., cxlii., 111, (Ann. Ch. Pharm., xcvii., 325).

WHITNEYITE, Min. p. 37.—From southern Arizona, analyses, Am. J. Sci., II., xlv., 306.
A variety from Fortuna di Paposa, Chili, *Bertrand*, Ann. d. Mines, VII., i., 413, 1872.

459 B. Willcoxite. Genth, Am. Phil. Soc. Philad., xiii., p. 397, 1873.
In scales white to greenish or grayish-white, with pearly lustre, and resembling talc.
Analyses, Kœnig (l. c.). 1. Shooting Creek; 2. Cullakenee Mine.

	$\ddot{\mathrm{Si}}$	$\dddot{\overline{\mathrm{Al}}}$	$\dddot{\overline{\mathrm{Fe}}}$	$\dot{\mathrm{Fe}}$	$\dot{\mathrm{Mg}}$	$\dot{\mathrm{Li}}$	$\dot{\mathrm{Na}}$	$\dot{\mathrm{K}}$	ign.
1.	28·96	37·49	1·26	2·44	17·35	tr	6·73	2·46	4·00 = 100·69
2.	29·50	37·56	1·40	2·38	17·20	tr	6·24	2·42	3·32 = 100·02

Oxygen ratio $\dot{\mathrm{R}} : \dddot{\overline{\mathrm{R}}} : \ddot{\mathrm{Si}} : \dot{\mathrm{H}} = 6 : 12 : 10 : 2$ nearly, or $3(2\dot{\mathrm{R}}, \ddot{\mathrm{Si}}) + 2\,(2\dddot{\overline{\mathrm{R}}}\,\ddot{\mathrm{Si}}) + 2\dot{\mathrm{H}}$.

B. B. fuses in fine splinters with difficulty to a white enamel, coloring the outer flame yellow. In hydrochloric acid decomposed with difficulty, with separation of silica in scales. Rare, occurring as a coating about a nucleus of corundum, and resulting from its alteration at Shooting Creek and Cullakenee Mine, Clay Co., No. Carolina.

Named in honor of Col. Joseph Willcox.

WILLEMITE, Min. p. 262.—Franklin, N. J., analyses, *Mixter*, Am. J. Sci., II., xlvi., 230, 1868; sp. gravity for transparent crystals 4·26, 4·25, 4·29, *Cornwall*, Am. Chemist., Oct., 1873, p. 126.
Altenberg, near Aachen, *Arzruni*, Pogg., clii., 281, 1874.

526 C. Winklerite, Breithaupt, Jahrb. Min., 1872, 816.
Amorphous, massive. H.=3. G.=3·432. Color bluish-black to violet-black. Streak dark-brown. Fracture conchoidal, with but slight lustre.
Analysis, Winkler (l. c.) 1. original analysis; 2. same after deduction of $\dddot{\overline{\mathrm{Fe}}}$ and $\ddot{\mathrm{Si}}$.

$\overset{.....}{\overline{\mathrm{As}}}$	$\dot{\mathrm{Cu}}$	$\dddot{\overline{\mathrm{Co}}}$	$\dot{\mathrm{Co}}$	$\dot{\mathrm{Ni}}$	$\dddot{\overline{\mathrm{Fe}}}$	$\dot{\mathrm{Ca}}$	$\ddot{\mathrm{Si}}$	$\ddot{\mathrm{C}}$	$\dot{\mathrm{H}}$
10·29	13·21	10·34	28·91	2·58	3·05	5·35	2·64	10·37	14·08=100·82
10·83	13·89	10·86	33·10			5·62		10·90	14·80=100·00

Breithaupt thinks that the mineral may have been formed by the gradual decomposition of erythrite (cobalt bloom) by water containing carbonic acid in the presence of some copper-mineral.

In the matrass gives off water. On charcoal decrepitates, but does not alter its appearance. B. B. infusible, coloring the flame green. With the fluxes gives reaction for cobalt. Effervesces with hydrochloric acid and the solution thus obtained upon heating evolves chlorine.

Found at Pria near Motril in Spain, occurring with galapectite, also with erythrite and malachite.

WINKWORTHITE, *How*, Phil. Mag., April, 1871.—Appendix I., p. 17.
Kenngott (Jahrb. Min., 1872, 300) repeats the suggestion of Brush that winkworthite is a mixture of gypsum and howlite.

WISERINE, Min. p. 528.—Cryst. memoir, with many new planes and discussion of relation to xenotime and zircon. Brezina remarks that the wiserine from the Binnenthal is very different in habit from that of other localities, and may possibly be a distinct species, Tsch. Min. Mitth., 1872, 8. Klein shows that the supposed mineral from the Binnenthal is in fact octahedrite, Jahrb. Min., 1872, 900.

WITTICHENITE, Min. p. 98.—Böckelsbach, Wittichen, Baden, anal., *Petersen*, Pogg., cxxxiv., 92; cxxxvi., 500. (Jahrb. Min., 1869, 337.)

ZEPHAROVICHITE, *Boricky*,—Ber. Ak. Wien, lix., 593, 1869.—Appendix I., p. 17.

572 A. **Zeunerite**. *Weisbach*, Jahrb Min., 1872, 207; 1873, 315; see also *Winkler*, J. pr. Ch., II., vii., p. 8, 1873; *Laube*, Lotos, xxii., 1872, p. 210; *Frenzel*, Jahrb. Min., 1873, 947.
Tetragonal. In crystals sometimes tabular, sometimes pyramidal, with planes *I*, *O*, *m*. Cleavage, basal perfect, the surface having a pearly lustre. H.=2-2·5. G.=3·2. Color grass-green and apple-green. In appearance and physical characters very similar to torbernite (Min. p. 585), with which it is isomorphous according to Weisbach.*
Analyses, Winkler, 1. l. c., 2. quoted by Weisbach l. c.

	$\dddot{\text{As}}$	$\bar{\text{U}}$	$\dot{\text{Cu}}$	$\dot{\text{H}}$		
1.	20·94	55·86	7·49	15·68		= 99·97
2.	15·1	55·6	8·7	14·5	($\dot{\text{Fe}}$ 5·2, $\dot{\text{Ca}}$ 1·2)	= 100·3

---

* See *Schrauf*, Tsch. Min. Mitth., 1872, 181.

From analysis 1. Winkler writes $\dot{C}u\ 2\ \overline{\ddot{U}}\ \overset{...}{\overline{A}}s + 8\dot{H}$.

First found with other uranium minerals at the mine Weisser Hirsch, near Schneeberg, Saxony; the crystals rest upon quartz or upon iron ochre. Since identified from Geisterhalde, near Joachimsthal, Laube (l. c.), and from Huel Gorland, Cornwall (on smoky quarz with chalcocite and melaconite), and from Zinnwald, Saxony (on quarz), Frenzel (l. c.).

Winkler (l. c. p. 14) has made zeunerite artificially, having the following composition: $\dot{C}u$ 7·01, $\overset{...}{\overline{A}}s$ 22·11, $\overline{\ddot{U}}$ 57·21, $\dot{H}$ 14·65 = 100·98.

ZINCITE, Min. p. 135.—Artificial oxyd of zinc in twinned crystals, v. Rath, Pogg., cxliv., 580, 1871.

Hayes has investigated the zincite from New Jersey, and thinks he has confirmed his previous observations that the red color is due to the presence of scales of hematite (Am. J Sci., III., iv., 191, 1872). The writer has made a study of some thin sections under the microscope, and has found that while there are present, at times, irregular scales (the hematite of Hayes) the red or yellow color is always uniformly diffused, and is not due to these scales. See Dana, Min. p. 136.

ZIRCON, Min. p. 272.—Observed in the hypersthenyte, near Harzburg, *Rose*, ZS. G. Ges., xxii., 754.

Expailly, France, anal., *Mylander*, Jahrb. Min., 1870, 488.

Ceylon, analyses, *Forbes*, Chem. News, xxv., 305, June, 1872.

Zirlite. Pichler has given this name to an opal-like hydrate of alumina closely related to, if not identical with, gibbsite. Found at Zirl, in the Tyrol (Jahrb. Min., 1871, 57; 1875, 51).

Zoblitzite. See LIMBACHITE.

ZOISITE, Min. p. 290.—Tuscany, province of Lucca, *Achiardi*, Boll. Com. Geol. Ital., 1871, 137.

No. Carolina, *J. L. Smith*, Am. J. Sci., III., vi., 184; *Genth*, Am. Phil. Soc. Philad., viii., 374, 406, 1873.

Thulite, Norway, anal., Herter, ZS. G. Ges., xxiii., 268.

Rammelsberg, ZS. G. Ges., xxiv., 649.

Zonochlorite, Foote, Rep. Amer. Assoc., 1873, p. 65.

Associated with laumontite, stilbite, prehnite and related minerals in the amygdoid of Neepigon Bay, Lake Superior.

Massive, banded with different shades of dark-green. H.=6½–7. G.=3·113. Water determinations gave 8·7, 12·9 and 7·03 p. c., and the presence of iron and alumina, also lime and soda (spectroscope) was proved. B. B. fuses with difficulty to a dark glass, and with fluxes reacts for iron. Upon this very imperfect examination the author concludes that the species is new. [Probably identical with chlorastrolite, Dana, Min., p. 412.]

PARAGONITE.—**Cossaite.** Gastaldi has given this name to a mineral which in oxygen ratio and chemical composition is identical with paragonite, but he separates it from this species on the ground of the absence of distinct micaceous cleavage. He first identified it in an antique ring (possibly a bracelet) dug up in the neighborhood of Turin, but he has also found it at the mines of Borgofranco, near Ivrea, and at Mt. Blasier.

The description as given by Prof. Cossa is as follows:

Structure crystalline, finely lamellar; in some portions having a micaceous aspect (Borgofranco; this tendency to micaceous structure is absent in the mineral from Mt. Blasier). Opaque, slightly translucent on the edges. H. = 2.5. G. = 2·896 and 2·890. Color green. Streak white.

Analyses; 1. and 2. by Cossa, l. c. 1. Borgofranco; 2. Mt. Blasier; 3. paragonite, Rammelsberg (Dana, Min., p. 488).

	$\ddot{S}i$	$\overline{\dddot{A}}l$	$\overline{\dddot{F}}e$	$\dot{M}g$	$\dot{C}a$	$\dot{N}a$	$\dot{K}$	$\dot{H}$		
1. Cossaite.	46·67	39·02	2·01	——	——	6·37	1·36	4·91	= 100·38	Cossa.
2. "	46·68	39·88	1·06	——	——	6·91	0·84	5·08	= 100 45	Cossa.
3. Paragonite.	46·81	40·06	tr.	0·65	1·26	6·40	tr.	4·82	= 100	Ramm.

The oxygen ratio for $\dot{R} : \overline{\dddot{R}} : \ddot{S}i : \dot{H} = 1 : 9 : 12 : 2$.

B.B. fusible with difficulty; exfoliates and becomes opaque white, moistened with cobalt solution; after ignition gives an intense blue color. Not decomposed by hydrochloric acid. Gastaldi calls the cossaite a soda-oncosin (pinite). He adds the following analysis by Cossa of what he considers a normal oncosin from Fenestrelle: $\ddot{S}i$ 47·96, $\dddot{A}l$ 31·03, $\dot{C}a$ 1·07, $\dot{M}g$ 3·42, $\dot{K}$ 10·44, $\dot{N}a$ 4·08, $\dot{H}$ 2·41 = 100·41. (*O.* ratio $\dot{R} : \dddot{R} : \ddot{S}i = 1 : 3 : 6$.) Very similar to cossaite in physical characters. B.B. fusible. (Atti Accad. Sci. Torino, x., Dec., 1874).

652 A. Guanovulite, *Wibel*, Ber. Chem. Ges. Berlin, 1874, 392.

Found in crystalline deposits filling the eggs of birds in Peruvian guano. H. = 2. G. = 2·33–2·65. Color yellowish-white. Lustre silky. An analysis gave, after deduction of impurities, $\dot{K}$ 35·49, NH_4O 5·09, $\dddot{S}$ 49·60, $\dot{H}$ 9·82 = 100·00. Wibel writes the formula $NH_4O\dddot{S} + 2\dot{K}\dddot{S} + 3(\dot{K}\dddot{S}, \dot{H}\dddot{S})$ + 4 aq.

In water it dissolves, leaving a very small residue, and giving a light-yellowish solution, which has a salty taste. Insoluble in ether or alcohol. Heated in a glass tube it first loses water and ammonia, then becomes black, and on stronger heating melts and gives off much sulphuric acid.

THIRD APPENDIX

TO THE

FIFTH EDITION

OF

DANA'S MINERALOGY,

BY

EDWARD S. DANA,

CURATOR OF MINERALOGY, YALE COLLEGE.

COMPLETING THE WORK TO 1882.

NEW YORK:
JOHN WILEY AND SONS,
53 East Tenth Street,
Second door west of Broadway.
1890.

COPYRIGHT,
1882,
BY E. S. DANA.

PREFATORY NOTE.

THIS Third Appendix to the fifth edition of the System of Mineralogy is designed to make the work complete up to January, 1882. Its publication has been unavoidably delayed long after the date originally set for its completion. The fact that seven years have elapsed since the issue of the Second Appendix (March, 1875), will be a sufficient explanation of the perhaps inconvenient length to which it extends.

This Appendix contains: (1), full descriptions of all species announced asnew since the publication of Appendix II.; and (2), references to all important mineralogical articles which have been published during the same period, with citations from them of many new analyses and new facts as to physical characters and localities. Under each species the entries are, for the most part, arranged under two heads: that of Crystallization (**Cryst.**), for the articles which treat of the crystalline form; and that of Analyses (**Anal.**), for those containing chemical analyses, with or without other matter.

The number of "new species" is very large, aggregating fully three hundred (300). Unfortunately the original descriptions of a large part of them are very incomplete, and in too many cases the names are contributions only to the nomenclature of the Science. If two very simple rules could be conscientiously followed by those investigating supposed new species, the Science of Mineralogy would be vastly benefited. These are: first, that the material analyzed should in every case be proved by a careful microscopic and chemical examination to be *homogeneous;* and, second, that the thorough investigation which is to establish the position of a "new species" should *precede*, not follow, the giving of a new name. A mineral which can be only partially described does not deserve a name.

In the classified list of new names on p. xi., those which seem to have a fair claim to recognition (including the names of some well-characterized varieties) are placed first. Following these in each division, are given in a paragraph the names, (1), of ordinary varieties having no especially distinctive character; (2), of imperfectly described or doubtful species, for which further study is much to be desired; and (3), of those so-called species which are obviously bad. The names of all species, new and old, are arranged in the body of the work in alphabetical order; the former are printed in black-faced type. References are given both to the System and also to Appendixes I. and II.; Appendix III. is, consequently, an index for the earlier Appendixes.

The Bibliography includes a list of mineralogical works published since January, 1875. To this is added a list of new journals devoted wholly, or in part, to mineralogical subjects, and also a list of memoirs upon a single subject of more than ordinary importance. For the explanation of *Abbreviations*, see the System, pp. xxxv.-xlv., and also this Introduction, p. viii. The thanks of the writer are due to Professor George J. Brush for his kindness in reading a set of the proofs as the work was going through the press.

NEW HAVEN, *April 1st*, 1882.

R. Comitato Geologico d' Italia; Bolletino (*Boll. Com. Geol.*). Commenced in 1869, published in yearly volumes of 12 numbers.

Bulletin de la Société Minéralogique de France (*Bull. Soc. Min.*). Commenced in 1878, published in yearly volumes of 8 or 9 numbers.

Geologiska Föreningens i Stockholm Förhandlingar (*Geol. För. Förh.*). Commenced in 1872. Vol. i. (Nos. 1 to 14), 1872–73; ii. (Nos. 15 to 28), 1874–75; iii. (Nos. 29 to 42), 1876–77; iv. (Nos. 43 to 56), 1878–79; v. (Nos. 57 to 70), 1880–81.

The Mineralogical Magazine and Journal of the Mineralogical Society of Gt. Britain and Ireland (*Min. Mag.*). Commenced April, 1876. Vol. i. (Nos. 1 and 2, 1876, 3–7 incl., 1877); ii. (Nos. 8, 9, 10, 1878; 11, 12, 12*, 1879); iii. (Nos. 13, 14, 15, 1879; 16, 17, 1880; iv. (Nos. 18, 19, 1880; 20, 1881).

Mineralogische Mittheilungen gesammelt von G. Tschermak (*Min. Mitth.*). Commenced 1871. Since 1878 published in separate form of smaller size as

Mineralogische und Petrographische Mittheilungen (*Min. Petr. Mitth.*), in yearly volumes of 6 numbers. Vol. i., 1878; ii., 1879; iii., 1880; iv., 1881.

Zeitschrift für Krystallographie und Mineralogie, unter Mitwirkung zahlreicher Fachgenossen des In- und Auslandes, herausgegeben von P. Groth (*Z. Kryst.*). Commenced in 1877, published in yearly volumes of 9 numbers. Numbers 1 and 2 of each volume are generally published in the closing part of the preceding year.

Annalen der Physik und Chemie: long known as Poggendorff's Annalen (*Pogg. Ann.*); since 1877 published by G. Wiedemann, and hence called Wiedemann's Annalen (*Wied. Ann.*). Three volumes annually; vols. i., ii., 1877; iii., iv., v., 1878, etc.

Neues Jahrbuch für Mineralogie, Geologie und Palæontologie, etc. (*J. Min.*). Since 1880 (strictly Oct., 1879), edited by E. W. Benecke, C. Klein, and H. Rosenbusch; and published in two volumes yearly. Vol. 1880, i., ii. ; 1881, i., ii. Also Beilage-Band i., Heft I., 1880, II., 1881, III., 1882. In the regular volumes the original memoirs and the abstracts of papers (*Referate, ref.*) are separately paged. An Index to the Jahrbuch for 1870–79 was issued in 1880.

V.—MEMOIRS ON THE "OPTICAL ANOMALIES" OF SOME CRYSTALLIZED MINERALS.

The question as to the true explanation of the "optical anomalies" presented by many crystallized minerals has been widely discussed in the past few years. That the crystals of many species exhibit in polarized light optical phenomena, not in harmony with their apparent geometrical form, has long been recognized; and the explanations which have been offered in earlier years are well understood: that is, the theory of lamellar polarization of *Biot*, of internal tension of *Reusch*, of disturbed molecular structure of *Marbach*, and so on. The recent discussion of this subject has taken a wide range, and many new facts have been recorded. Attention has been especially directed to it by the classical memoir of *Mallard*, the importance of which cannot be overestimated, even if his conclusions are not always accepted (for title see below). According to Mallard's view, as far as it can be explained in a word, these optical anomalies are explained on the assumption that the crystal exhibiting them is in fact made up of separate individuals regularly grouped, which are of a lower grade of symmetry than that which the complete form simulates. Thus, an apparent isometric cube may be made up of 6 square pyramids, each optically uniaxial, placed with their vertices at the centre of the solid, and their bases forming its sides. Similarly an apparent isometric octahedron may be made up of eight anisotropic triangular pyramids grouped in an analogous manner; and so on. Mallard thus includes under *pseudo-isometric* species: alum, analcite, boracite, fluorite, garnet, and senarmontite; among the *pseudo-tetragonal* species: apophylite, brookite, mellite, octahedrite, rutile, vesuvianite, zircon; among *pseudo-hexagonal* species: apatite, beryl, corundum, penninite, ripidolite, tourmaline; *pseudo-orthorhombic* species: harmotome, topaz; *pseudo-monoclinic*, orthoclase (microcline). Many additional facts to which the hypothesis of Mallard is applicable have been published by *Bertrand* (see below, and under the various species in the body of this work), who has also devised an arrangement of the microscope by means of which, with a high magnifying power, optical investigations may be made in many cases where it was before impossible. *Grattarola* includes calcite, quartz, nephelite, barite, etc. in the list of species which have an apparent symmetry higher than that which really belongs to them; his conclusions, however, are not based upon observations.

In many other cases observers have, on the basis of variation in angles, or of optical characters, reached the conclusion that the species in question really belongs to a system of lower symmetry than that to which it has been ordinarily referred. These cases are recorded in Appendixes II. and III. These last named observations, however, do not in most cases admit of being explained on the hypothesis of Mallard. In many of them the conclusions reached are beyond doubt correct, in others the question must be regarded as still undecided.

Tschermak proposes the term *mimetic* for those forms ("mimetische Formen"), which imitate a higher grade of symmetry by the grouping (twinning) of individuals of a lower grade of symmetry, as for example, aragonite.

Mallard's hypothesis has been opposed by various investigators on the ground that it does not explain many observed facts and is decidedly at variance with others. The observations of *Klocke*, *Jannettaz*, *Klein*, *Ben Saude*, are especially to be mentioned. A few of the facts bearing upon the question are given under boracite (p. 17) and analcite (p. 5). Klocke shows that the same crystal of alum may contain truly isotropic (normal) and anisotropic (abnormal) portions; also that the so-called distortion of the crystals and their position during their formation influences the optical phenomena observed. He shows, also, that preparations of gelatine, hardened under tension, show all the optical phenomena of the crystals under discussion. This subject cannot be elaborated here; it is enough to say that the observations of the mineralogists mentioned, as also of others, seem to confirm the view of Reusch, that at least in many cases (e. g. analcite, garnet, vesuvianite, etc.) the "optical anomalies" are to be explained as due to the state of molecular tension existing within the crystal. The investigation of this subject cannot, however, be regarded as entirely completed. A good general review of this subject is given by Zirkel in the 11th edition of Naumann's Mineralogy, pp. 152 et seq., also p. 722, 1881. The following are titles of important papers bearing upon this subject.

Arzruni u. Koch, S. Ueber den Analcim, Z. Kryst. v., 488, 1881.

Baumhauer. Ueber den Perowskit, Z. Kryst., iv, 187, 1879.

Becke. Über die Zwillingsbildung und die optischen Eigenschaften des Chabasit, Min. Petr. Mitth., ii., 391, 1879.

Ben Saude. Ueber den Analcim, J. Min., 1882. i., 41.

Bertrand. Sur les différences entre les propriétés optiques des corps cristallisées biréfringents, et celles que peuvent présenter les corps monoréfringents après qu'ils ont été modifiés par des retraits, compressions, dilatations, ou toute autre cause, Bull. Soc. Min., v., 3, 1882.

APPENDIX III.

Abriachanite. *Heddle*, Min. Mag., iii., 61, 193, 1879. *Aitken*, ib. p. 69. "An apparently new mineral," *Jolly and Cameron*, Q. J. G. Soc., xxxvi., 109, 1880.

Amorphous, clay-like; sometimes showing a distinct fibrous structure; also pulverulent. Color bright ultramarine blue. G. = 3·326 Heddle; 2·01 J. and C. Analyses: 1, Heddle, fragments from Dochfour; 2, Heddle, similar material crushed and then washed by decantation; 3, mean of several analyses from different localities, Jolly and Cameron.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	Na_2O	K_2O	H_2O		
1.	51·15	....	14·92	9·80	0·30	10·80	1·12	6·52	0·63	4·77*	S tr.	= 100·01.
2.	52·40	....	9·34	15·17	0·40	10·50	1·17	7·11	0·61	1·00		= 100·67.
3.	55·02	3·37	19·03	3·83	....	12·95	2·53	1·74	....	1·45	P_2O_5 0·33	= 100·25.

* Loss 0·95 at 100° C.

B. B. infusible, but loses color. Occurs abundantly in seams and cavities of the gneiss and granite of the Abriachan district, near Loch Ness, in Inverness-shire, Scotland.

[The material examined by Heddle, and that analyzed by Jolly and Cameron, was derived, at least in part, from the same source, and was similar in appearance; although in specific gravity there is a wide discrepancy, and the analyses do not entirely agree, especially as regards the alkalies. Heddle's analysis is near crocidolite (compare anal. 3, Min., p. 243). The facts at least prove the correctness of the opinion expressed by Jolly and Cameron, that, until a more complete examination can be made on purer material, the substance does not deserve a new name.]

ACANTHITE, Min., p. 51; App. II., p. 1.—*Groth* has described crystals from Annaberg, which are orthorhombic with marked monoclinic symmetry, Min.-Samml., Strassburg, p. 51, 1878.

Achrematite. *J. W. Mallet*, J. Chem. Soc., II., xiii., 1141, 1875.

Massive, crypto-crystalline. Tetragonal or hexagonal (?). H. = 3–4. G. = 5·965, in powder, 6·178. Color pale sulphur-yellow to orange and red, in the mass liver brown, from admixed limonite. Streak pale cinnamon brown. Lustre resinous to adamantine. Translucent on thin edges. Fracture uneven to subconchoidal. Brittle. Analyses:

	As_2O_5	P_2O_5	MoO_3	PbO	Pb(for Cl)	Cl	Fe_2O_3	H_2O	F,Cu,Ag	
1.	15·90	0·02	4·58	60·35	5·51	1·89	9·93	1·63	tr.	= 99·81.
2.	16.25	0·03	4·40	62·32	5·48	1·88	8·53	1·38	tr.	= 100·27.
3.	15·75	0·02	4·19	56·77	5·48	1·88	13·08	2·27	tr.	= 99·44.

The iron and water are present in the amount required for limonite, the presence of which is suggested by microscopic examination; this limonite is deducted, viz., 11·56 p. c. for (1), 9·91 for (2), and 15·35 for (3); then calculating to 100, the results are:

	As_2O_5	MoO_3	PbO	Pb(for Cl)	Cl	
1.	18·02	5·19	68·40	6·25	2·14	= 100.
2.	17·99	4·87	68·99	6·07	2·08	= 100.
3.	18·73	4·98	67·53	6·52	2·24	= 100.
Mean	18·25	5·01	68·31	6·28	2·15	= 100.

The formula calculated is $3\,[3Pb_3As_2O_8 + PbCl_2] + 4\,[Pb_2MoO_5]$. [That the mineral is homogeneous, and not a mixture of an arsenate and molybdate of lead, is considered by the author as sufficiently proved; but the composition proposed is certainly not a probable one]. B. B., decrepitates slightly, turns dark brick-red, and fuses easily to a nearly black globule, which shows indistinct crystalline facets on cooling. On charcoal yields arsenical odors, a lead coating, and finally globules of lead. With the fluxes, reacts for iron, which, however, is only present as an impurity.

From the mines of Guanaceré, Chihuahua, Mexico. Named from ἀχρήματος, *useless*, in allusion to the fact that it was received as a silver ore, while, in fact, of no intrinsic value.

ACHTARAGDITE.—Min., p. 478; App. II., p. 1.

ACMITE, Min., p. 224; App. II., p. 1.—**Anal.** and discussion of composition, Norway, *Dölter*, Min. Petr. Mitth., i., 379, 1878.

Probable occurrence at Ditró, Transylvania, *Becke*, Min. Petr. Mitth., i., 554, 1878.

ADAMITE, Min., p. 565.—From the ancient mines recently reopened at Laurium, Greece. —Occurrence announced, *Klien*, J. Min., 1878, 53; cryst. and optical description, *Des Cloizeaux*, C. R., lxxxvi., 88, Jan., 1878; cryst. description, *Laspeyres*, Z. Kryst., ii., 147, Feb., 1878; *Des Cloizeaux*, Bull. Soc. Min., i., 30, May, 1878.

Occurs in small crystals, colorless to deep emerald green, implanted on smithsonite; also in radiated mammillary groups. The forms, as shown independently by Des Cloizeaux and Laspeyres, are closely similar to those of the original mineral from Chili, as also of that from Cape Garonne (App. II., p. 1). Laspeyres finds that, with identical prismatic angles, the vertical axes in the colorless and deep green crystals differ, as 20 : 19 respectively; the habit is also different. An analysis of the green mammillary variety gave Friedel (Bull. Soc. Min., i., 31) As_2O_5 40·17, ZnO 55·97, CuO 0·64, FeO 0·18, H_2O 4·01 = 100·97.

ÆGIRITE, Min., p. 223; App. II., p. 1.—**Anal.**, Hot Springs, Arkansas, *J. L. Smith*, Am. J. Sc., III., x., 60, 1875. Analysis and discussion of composition, *Dölter*, Min. Petr. Mitth., i., 374, 1878.

Aërinite. *v. Lasaulx*, J. Min., 1876, 352; *Des Cloizeaux*, ib., 1877, 60 (Bull. Soc. Min., i., 125, 1878). A compact, earthy mineral, of a bright blue color, from the Pyrenees. H. = 3-4, G. = 3·018. Shown by Des Cloizeaux to be a heterogeneous mass, consisting of a blue paste, inclosing different minerals, perhaps owing its blue color to artificial means. Analyses: 1, Lasaulx (see also J. Min., 1877, 60); 2, *id.*, part (18·28 p. c.) soluble in HCl (in other trials 29·17 p. c., and 32·45 p. c., went into solution); 3, Damour; 4, *id.*, insoluble portion; 5, *id.*, soluble portion; 6, total of 4 and 5; 7 and 8, Rammelsberg, ZS. G. Ges., xxviii., 234, 1876.

	SiO_2	Al_2O_3	Mn_2O_3	Fe_2O_3	FeO	MgO	CaO	K_2O	H_2O

8.	44·00	15·39	....	8·88	3·16	2·44	13·88	....	13·00	= 100·75.

[It seems to be sufficiently proved that the substance above described is not be regarded as a mineral species.]

ÆRUGITE.—App. II., p. 1.

ÆSCHYNITE, Min., p. 522.—**Cryst.**, Hitterö, Norway, *Brögger*, Z. Kryst., iii., 481, 1879. Miask, an analysis has afforded *Rammelsberg* (ZS. G. Ges., xxix., 315, 1877),

Cb_2O_5	TiO_2	ThO	$(Ce,La,Di)_2O_3$	Y_2O_3, Er_2O_3	Fe_2O_3	CaO	
32·51	21·20	17·55	19·41	3·10	3·71	2·50	= 99·98.

The formula deduced from this is $[R_2]Cb_2(Ti,Th)_3O_{14}$, or $[R_2]Cb_2O_8 + 3(Ti,Th)O_2$.

Aglaite.—See *Spodumene*, p. 112.

AGRICOLITE.—App. II., p. 1.

Ajkite. A resin near amber, Ajka, Hungary (Bull. Soc. Min., i., 126, 1878).

ALABANDITE, Min., p. 46.—**Anal.**, Morococha, Peru, *Raimondi*, Min. Pérou, p. 239, 1878.

Alaskaite. *G. A. König*, Am. Phil. Soc., Philad., 1881, 472, or Z. Kryst., vi., 42.

Massive, small foliated, with occasional cleavage planes. G. = 6·878. Lustre metallic. Color whitish lead-gray. Powder bluish gray. Opaque. Easily friable in the mortar. Analyses : 1; 1*, after deducting from (1) 2·28 p. c. chalcopyrite, and 15 p. c. barite ; 2, independent variety.

	S	Bi	Sb	Pb	Ag	Cu	Fe	Zn	Insol.
1 (⅔)	15·85	46·87	0·51	9·70	7·10	3·64	0·70	0·64	15·00 = 100·01.
1*	17·63	56·97	0·62	11·79	8·74	3·46	....	0·79	..... = 100.
2 (⅓)	17·85	51·35	....	17·51	3·00	5·38	1·43	0·20	2·83 = 99·55.

For (1*) the ratio of R : Bi : S = 1 : 2·02 : 4·14, and for (2) after deducting as in (1) = 1 : 1·89 : 3·88, or, approximately 1 : 2 : 4, corresponding to $(R_2,R)S + Bi_2S_3$, with R_2 = Ag_2, Cu_2, and R = Pb.

B. B. in closed tube decrepitates, and melts without giving a sublimate ; in the open tube gives fumes of SO_2 and a slight sublimate of Sb_2O_3. On charcoal a lead coating, and on continued blowing that for silver ; also with potassium iodide and sulphur, a strong reaction for bismuth. After roasting reacts for copper and iron with the fluxes. Slowly attacked by cold concentrated HCl, rapidly decomposed by the hot acid, leaving flocculent silver chloride.

Occurs intimately mixed with quartz, barite, chalcopyrite, and tetrahedrite, at the Alaska mine, Poughkeepsie Gulch, Colorado.

Rammelsberg (ZS. G. Ges., xxix., 80, 1877) has described under the name of SILBERWISMUTHGLANZ, a mineral which is the bismuth compound corresponding to miargyrite, and is very near alaskaite.—Massive, soft. G. = 6·92. Color gray. Streak light gray. Analysis (⅓) after deducting admixed galenite : S 17·24, Bi 54·50, Ag 28·26 = 100. This corresponds to $AgBiS_2$, or $Ag_2S + Bi_2S_3$, requiring S 17·0, Bi 54·7, Ag 28·3 = 100. B. B. on charcoal fuses readily, giving a coating of bismuth oxide, and after long blowing a globule of silver. Soluble in HNO_3 with separation of sulphur. Associated with tetrahedrite, galenite, sphalerite and pyrite at the Matilda mine, near Morococha, Peru. [The two minerals above described are essentially identical, and as the name of Rammelsberg cannot be employed outside of Germany, that of König may be accepted to cover both. The corresponding mineral, miargyrite, has also some varieties which contain lead.]

ALBITE, Min., p. 348; App. II., p. 1.—**Cryst.** Kuchelbad, near Prague, Bohemia, *Vrba*, Ber. Böhm. Ges., 1879, 472, and Z. Kryst., iv., 360, 1880. Switzerland, *vom Rath*, Z. Kryst., v., 27; Zöptau, ibid., v., 253, 1880. Mt. Cau., Pyrenees, *v. Lasaulx*, Z. Kryst., v., 341, 1881.

ALLOPHANE, Min., p. 419; App. II., p. 2.—**Anal.**, Steinbrück, *Gamper*, Verh. Geol. Reichs., 1876, 354.

Muck describes (Z. Berg.-Sal.-Wesen., xxviii., 192, 1880) an earthy, white to pale wine yellow, or greenish yellow substance, from the clay of the Schwelm mine. It corresponds with the *kieselalluminite* of Kornwestheim (Min., p. 420), but the name SULFATALLOPHAN is preferred, as it behaves like allophane. Soluble in HCl. Analyses: 1, yellowish, translucent; 2, white, earthy; 3, soft, of butter-like consistency; 4, kieselalluminite.

	SiO_2	Al_2O_3	SO_3	H_2O
1.	14·84	38·55	7·98	38·63.
2.	18·74	36·73	6·04	38·49.
3.	21·83	40·07	10·54	27·52.
4.	13·06	42·59	5·04	39·32.

As remarked by Muck, these substances are varying mixtures of aluminum silicate and basic aluminum sulphate.

Wallerawang, New South Wales, *Liversidge*, Proc. R. Soc., N. S. W., Nov. 3, 1880.

ALVITE, Min., p. 511.—According to a suggestion of *W. C. Brögger* (Geol. För. Förh., v., 352, 1881), alvite is to be regarded as simply zircon and xenotime, compounded as described by Zschau (Min., p. 529). Crystals from Ånneröd, near Moss, Norway, gave him 36·58 SiO_2 and 18·84 P_2O_5, supporting this view. [This may be true of some so-called alvite, but can hardly apply to the mineral originally analyzed by Forbes.]

AMALGAM, Min., p. 13; App. II., p. 2.—Domeyko (3d Ed. Min., Chili, p. 358, 1879) describes several varieties of silver amalgam from Chili. One of these from the mines of Arqueros, Coquimbo, Chili, has Ag 94·4, Hg 5·6, and corresponds to *kongsbergite* (App. II., p. 32). Another has Ag 69·21, Hg 30·76, and is called *bordosite* (but see App. II., p. 8) from the locality, the mines of Bordos. Various intermediate compounds are mentioned.

An amalgam from Vitalle Creek, British Columbia, lat. 53° N., afforded: Ag 86·15, Hg 11·90, SiO_2 0·45 = 98·50 (*Hanks*, priv. contrib.); it hence corresponds with *arquerite* (Min., p. 14). An amalgam from the Sala mine, Sweden, gave *Nordström*: Ag 46·30, Hg 51·12, Fe 0·81, Zn, Pb, tr., $CaCO_3$ 0·21, insol., 1·01 = 99·45, Geol. För. Förh., v., 715, 1881.

AMBLYGONITE, Min., p. 545.—**Analyses** by *Penfield*, Am. J. Sc., III. xviii., 295, 1879.

	P_2O_5	Al_2O_3	Li_2O	Na_2O	H_2O	F	
1. Penig, (½)	48·24	33·55	8·97	2·04	1·75	11·26	Mn_2O_3 0.18 = 105·94, deduct 4·74 O (= F) = 101·20.
2. Montebras, A. (½) G. 3.088	47·09	33·22	7·92	3·48	2·27	9·93	CaO 0·24 = 104·15, deduct 4·02 O = 100·13.
3. Auburn, Me. (½) G. = 3·059	48·48	33·78	9·46	0·99	3·57	6·20	= 102·48, deduct 2·61 O = 99·87.
4. Hebron, Me., A.	[48·53]	34·12	9·54	0·34	4·44	5·24.	
5. Paris, Me. (½) G. = 3·035	48·31	33·68	9·82	0·34	4·89	4·82	K_2O 0·08 = 101·89, deduct 2·03 O = 99·86.
6. Hebron, Me., B. (½) G. = 3·032	47·44	33·90	9·24	0·66	5·05	5·45	= 101·74, deduct 2·29 O = 99·45.
7. Branchville, Ct. (½) G. = 3·032	48·80	34·26	9·80	0·19	5·91	1·75	Fe_2O_3 0·29, Mn_2O_3 0·10 = 101·10, deduct 0·74 O = 100·36.
8. Montebras, B. (½) G. 3·007	48·34	33·55	9·52	0·33	6·61	1·75	CaO 0·35 = 100·45, deduct 0·74 O = 99·71.

These analyses are arranged so as to show the variation in the relative amounts of water and fluorine. For all of them the author shows that the ratio of P : Al : R : (F,OH) = 1:1:1:1 nearly, corresponding to the formula $Al_2P_2O_8 + 2R(F,OH)$. The conclusion reached is that the varieties (see *hebronite* and *montebrasite* in Appendixes I. and II.) differ only in the extent to which the fluorine is isomorphously replaced by hydroxyl (HO). See also *triploidite*, in this Appendix.

Occurrence at Montebras, with analyses, *Thenard*, Monit. Scientif., III., ix., 1175 (Jahresb. Ch., 1879, 1204).

AMBLYSTEGITE.—App. I., p. 1.

AMBROSINE.—App. I., p. 1.

Amesite.—See *Corundophilite*, p. 31.

Practical determination by optical methods in thin sections of rocks, *Fouqué* and *Lévy*, Ann. Min., VII., xii., 429, 1877; *Thoulet*, ib., xiv., 111, 1878.

Analyses of Scottish varieties, and discussion of results of alteration, *Heddle*, Trans. Soc. Edinb., xxviii., 502, 1878. Amelia Co., Va., *Massie*; Amherst Co., Va., *Baker*, Ch. News, xlii., 194, 1880.

A variety of amphibole containing no magnesia is called BERGAMASKITE, by *Lucchetti* (Mem. Acc., Bologna, IV., ii., 397, 1881; Z. Kryst., vi., 199). Occurs in a quartzose hornblende-porphyry, from Monte Altino, Province of Bergamo, Italy. Forms acicular crystals, vertically striated, and arranged in parallel or radiated groups; cleavage prismatic, 124°. G. = 3·075. Analysis: (½) SiO_2 36·78, Al_2O_3 15·13, Fe_2O_3 14·46, FeO 22·89, CaO 5·14, MgO 0·93, Na_2O 4·00, K_2O 0·42, loss [0·25], MnO tr. = 100; characterized by the small amount of magnesia present.

A manganesian (1·37 p. c. MnO) variety from Edwards, St. Lawrence Co., N. Y., was described under the name HEXAGONITE, as "a new hexagonal bisilicate," by *Goldsmith* (Proc. Acad. Nat. Sc., Philad., 1876, 160). Its true character was shown by *König* (ib., p. 180).

Bertels (Verh. Würzb. Ges., II., viii., in Jahresb. Ch., 1874, 1267) has given the name PHÄACTINITE to an alteration product of amphibole, forming radiated masses, doubly refracting. H. = 2. G. = 2·997–3·057. Color dirty grayish brown. Analysis after deducting a little magnetite: SiO_2 35·5, Al_2O_3 16·9, Fe_2O_3 25·4, MnO 1·4, MgO 5·3, CaO 7·2, H_2O 8·1 = 99·8, corresponding approximately to $R_3[R_2]_2Si_4O_{14} + 3$ aq. From the rock called by the same author isenite, occurring in Nassau, Germany. [An uncertain decomposition product hardly deserves a distinct name; the substance is not very far from delessite.]

ANALCITE, Min., p. 432; App. II., p. 2.—**Cryst.** Kerguelen Is., *Laspeyres*, Z. Kryst., i., 204, 1877. Radauthal, *Lüdecke*, Z. gesammt. Nat., III., iv., 325, 1879.

Anal., Montreal, Canada, *Harrington*, Geol. Canada, 1878. Bohemia, *Preis* and *Vrba*, Ber. Böhm. Ges., 1879, 467.

Bamberger shows (Z. Kryst., vi., 32, 1881) that Bechi's picranalcite is identical with ordinary analcite, containing only a trace of magnesia.

The question as to the CRYSTALLINE SYSTEM of analcite has been recently discussed, as follows: *Schrauf* (Anzeig. Ak. Wien, 1876), referred crystals from Friedeck, Bohemia, to the orthorhombic system, describing them as complex twins, analogous to those of leucite described by vom Rath. *Mallard* (Ann. Min., VII., x., 111, 1876) describes the optical anomalies of the species, and explains them by assuming that a crystal is formed by the interpenetration of three pseudo-tetragonal individuals, each one of which is formed of two orthorhombic crystals, with nearly equal axes; these 24 orthorhombic crystals, composing a single pseudo-isometric crystal, correspond to the 24 planes of a tetrahexahedron. *Lasaulx* (J. Min., 1878, 510) describes the results of an optical examination of crystals of picranalcite from Monte Catini, Tuscany, and concludes (but see below) that they can be only explained by the assumption that a crystal is made up of 12 triclinic individuals interpenetrating each other, analogous to the compound crystals of phillipsite (q. v.). *Schulten* (Bull. Soc. Min., iii., 150, 1880) has obtained trapezohedral crystals by artificial means, and on optical grounds claims for them a complex structure, analogous to that assumed by Mallard (see above); with him, however, the crystals are rhombohedral. Crystals obtained later by a different method were isotropic (ib., v., 7, 1882.)

On the other hand, later investigations by *v. Lasaulx* (Z. Kryst., v., 330, 1881) on crystals from the Cyclopean Is., have led him to the conclusion that the optical phenomena are to be explained (as formerly accepted) by reference to the varying degrees of tension existing in the interior of the crystal. *Arzruni* and *Koch* (Z. Kryst., v., 483, 1881) have also, after a review of the whole subject, and an extended optical examination of specimens, especially from Kerguelen Is. and the Cyclopean Islands, concluded that analcite is to be referred to the isometric system. Finally, the whole subject has been exhaustively reviewed and further investigated by *Ben Saude* (Inaug. Diss., Stuttgart, 1881, and J. Min., 1882, i., 41). He describes the results of an optical examination of sections of many crystals cut parallel to the cubic, octahedral, dodecahedral, and trapezohedral (2–2) planes, and shows that they do not correspond with *Mallard's* hypothesis, but can be explained on the supposition of internal tension. He found, further, that gelatine cast into moulds corresponding to the crystalline forms acquired on solidifying similar optical characters.

ANATASE.—See *Octahedrite*, p. 85.

ANKERITE, Min., p. 685; App. II., p. 3.—**Anal.**, Phenixville, Penn., ***König***, Proc. Ac. Nat. Sc. Phil., 1877, 290.

Boricky has examined a series of minerals from Bohemia, related to ankerite, and discusses the relation in composition between them and other similar carbonates (Min. Mitth., 1876, 47). He writes the general formula $CaFeC_2O_6 + x(CaMgC_2O_6)$, for all the related minerals, where x may have one of the values $\frac{1}{2}$, 1, $\frac{4}{3}$, $\frac{3}{2}$, $\frac{5}{3}$, 2, 3, 4, 5, 10; those varieties in which $x < 2$ are included under *ankerite*, and the remainder under the name *parankerite*. For normal ankerite he takes $x = 1$, and for normal parankerite $x = 2$.

Ånnerödite, *W. C. Brögger*, Geol. För. Förh., v., 354, 1881.

Orthorhombic: Axes—$\breve{c}:\bar{b}:\breve{a}$ = 0·36108 : 1. : 0·40369. Observed planes *i*-ī, *i*-ĭ, *O*, *I*, *i*-3̆, *i*-5̆, 2-ī, ½-ĭ, 1-ĭ, 1, 2, 2-2̄, 2-2̈, 3-3̆. *I* ∧ *I* = 136° 2′, *i*-3̆ ∧ *i*-3̆ = 100° 44′, 2-ī ∧ 2-ī = 58° 25′. In prismatic crystals of varied habit, often closely resembling columbite; planes sometimes developed according to monoclinic symmetry. Angles near those of columbite (the position taken is that of Schrauf, *I* = *i*-3̆, Min., p. 516), and also not far from those of polycrase. Twinning plane *i*-5̆. Many crystals often grouped in parallel position, thus forming an apparently single crystal of considerable size.

H. = 6. G. = 5·7 of anhydrous crystals. Lustre metallic to greasy submetallic. Color black. Streak dark blackish brown to brownish or greenish gray. Opaque, or translucent in very thin splinters. Fracture subconchoidal. Brittle. B. B., fuses on the edges to a black glass. Analysis by C. W. Blomstrand:

Cb_2O_5	SnO_2	ZrO_2	SiO_2	ThO_2	Ce_2O_3	Y_2O_3	UO	PbO	FeO	MnO	CaO	MgO	K_2O	Na_2O	Al_2O_3	H_2O
48·13	0·16	1·97	2·51	2·37	2·56	7·10	16·28	2·40	3·38	0·20	3·35	0·15	0·16	0·32	0·28	8·19 = 99·51.

Neglecting the silica, the formula calculated by Blomstrand is $R_2Cb_2O_7$ + 2¼ aq., which makes it nearly identical with samarskite, and also to the less certain nohlite (App. II., p. 41), except in the water; Brögger, however, shows that the water is not essential, but is due to a partial alteration which is accompanied by a lowering of the hardness (to 4·5) and specific gravity (to 4·28), and a loss of lustre. A crystal with G. = 5·7 showed only a trace of water. The mineral is consequently hardly to be separated from samarskite in composition, but it is different in form (see E. S. Dana, Am. J. Sc., III., xi., 201, 1876). Brögger shows further, that ånnerödite (euxenite and polycrase) bears the same relation to columbite that samarskite does to tantalite; the two last being very near in form, as are ånnerödite and columbite. From the pegmatite vein at Ånneröd, near Moss, Norway, where it is associated with monazite, alvite (q. v.), apatite, magnetite, beryl, topaz, and other minerals.

Anomite.—See *Mica Group*, p. 77.

ANORTHITE, Min., p. 337; App. II., p. 3.—**Cryst.**, Albani Mts., *Q. Sella*, Accad. Linc. Mem., III., i., 96, or Z. Kryst., i., 241, 1877. Pesmeda Alp, Monzoni, Tyrol, rose-red variety, *vom Rath*, Ber. nied. Ges. Bonn., July 2, 1877; anal. by *Gamper*, Verh. geol. Reichs., 1877, 134. Aranyer Berg, Transylvania, *vom Rath*, Z. Kryst., v., 23, 1880. Mt. Etna (cyclopite) *v. Lasaulx*, Z. Kryst., v., 326, 1880.

Expansion of crystals with heat, *Beckenkamp*, Z. Kryst., v., 441, 1881.

Pseudomorph, Franklin Furnace, N. J., *Ræpper*, Am. J. Sc., III., xvi., 364, 1878.

The esmarkite from Kjörrestad, in Bamle, Norway, is regarded by *Brögger* and *Reusch* (ZS. G. Ges., xxvii., 676, 1875) as probably a distinct species, although they show that it follows the same twinning laws as the anorthite of Vesuvius. For Des Cloizeaux's results see App. II., p. 19.

See also *Feldspar Group*, p. 45, and *Barsowite*, p. 12.

ANTHOPHYLLITE, Min., p. 231; App. II., p. 3.—Opt. exam., Bamle, Norway, *Des Cloizeaux*, C. R., lxxxiv., 1478, 1877. *Pisani* (C. R., lxxxiv., 1510) has analyzed the Bamle mineral (1), and also (2) the *snarumite* of Breithaupt (Min., p. 316). Des Cloizeaux (l. c.), in view of these analyses, and also of the relation in optical character, suggests that the snarumite may be an alteration product of an aluminous anthophyllite. Analysis 3 (by Rosenius) and 4 (by Stadius) are of an orthorhombic mineral referred to anthophyllite (G. = 3·022–3·045) from Stansvik, near Helsingfors, Finland, *F. J. Wiik* (Z. Kryst., ii., 498, 1878).

	SiO_2	Al_2O_3	FeO	MgO	CaO	Na_2O, K_2O	ign.	
1. Bamle, G. 2·98.	51·80	12·40	3·67	27·60	....	1·44	3·00	= 99·91.

3. Stansvik	51·74	8·55	20·35	16·45	1·79	0·41 MnO	....	= 99·29.
4. Stansvik	52·05	9·46	20·72	17·24	1·35	0·26 MnO	....	= 101·08.

ANTILLITE.—App. I., p. 1.

ANTIMONY, Min., p. 18.—Description of artificial crystals, *Laspeyres*, ZS. G. Ges., xxvii., 574, 1875.

APATITE, Min., p. 530; App. II., p. 8.—**Cryst.**, from different localities, *Groth*, Min. Samml., Strassburg, 174, 1878. Lama dello Spedalaccio, *Uzielli*, Accad. Linc. Mem., i., 159, 1876.

According to *Mallard* (Ann. Min., VII., x., 147, 1876), apatite is to be regarded as pseudo-hexagonal, being formed by the intergrouping of orthorhombic individuals; a thin section of a Schlaggenwald crystal showed three irregularly joined sectors, of different optical orientation, and each distinctly biaxial; others from Estremadura, Spain, showed six sectors, two opposite belonging to the same crystal. In other cases normal uniaxial characters were observed and explained by the intimate union of the different molecular aggregations.

Etching figures corresponding to the pyramidal hemihedrism, *Baumhauer*, Ber. Ak. München, 1875, 169. Pyro-electrical characters, *Hankel*, Wied. Ann., vi., 52, 1879. Absorption bands in spectrum (Ce, La, Di), *Cossa*, Accad. Linc. Mem., III., iii, 17 et seq., 1878.

Analyses, etc. Occurrence at Kjörrestad, Bamle, Norway, *Brögger* and *Reusch*, ZS. G. Ges., xxvii., 646, 1875. Nischne Novgorod (phosphorite), *v. Möller*, Verh. Min. Ges. St Pet., II., xii., 61. Method of occurrence in Canadian veins, often of immense size, *Harrington*, Geol. Canada, 1878; composition of Canadian apatites, *C. Hoffmann*, Geol. Canada, 1879.

Siewert (Z. Gesammt. Nat., II., x., 339, 1874) found 6·7 p. c. MnO in an apatite from San Roque, near Cordoba, Argentine Republic, and calls this variety, in which part of the calcium is replaced by manganese, MANGANAPATITE. *Penfield* (Am. J. Sc., III., xix., 367, 1880) has analyzed apatites from Branchville, Conn., and Franklin Furnace, N. J., containing manganese; one variety from Branchville afforded 10·59 p. c. MnO.

APHROSIDERITE, Min., p. 502; App. II., p. 3.—Striegau, Silesia, *Websky* (anal. by Rammelsberg), ZS. G. Ges., xxxi., 211, 1879.

ARAGOTITE, App. II., p. 4.—Optical examination, *Bertrand*, Bull. Soc. Min., iv., 87, 1881.

Arctolite. ARKTOLITE, *Blomstrand*, "Ett högnordiskt mineral," Geol. För. Förh., v., 210, 1880.

Occurs in a crystalline limestone, forming small irregularly curved crystalline plates, generally compact, occasionally showing prismatic angles of 124°–126° (Sjögren, l. c.). H. = 5. G. 3·03. Colorless or yellowish to greenish. **Analysis** (½): SiO_2 44·93, TiO_2 0·38, Al_2O_3 23·55, Fe_2O_3 1·24, CaO 13·28, MgO 10·30, Na_2O 1·78, K_2O 0·79, H_2O 3·15 =

99·74. This corresponds to the formula $H_2R_2[Al_2]Si_3O_{12}$. B. B. fuses with difficulty to a white enamel; partially attacked by acids with the separation of flocculent silica. Found in 1861 on Hvitholm, near Spitzbergen. [A relation to prehnite, on the ground of the composition, and to hornblende, because of the prismatic angle, is suggested, but the mineral needs further examination before its true character can be settled.]

ARDENNITE, App. II., p. 4.—Supplementary description by *v. Lasaulx*, J. Min., 1876, 363, and *Bettendorff*, Pogg. Ann., clx., 126, 1877. Analyses by Bettendorff, (1) sulphur-yellow opaque var., G. = 3·656; (2) brown transparent var., G. = 3·648.

	SiO_2	Al_2O_3	Fe_2O_3	MnO	CuO	MgO	CaO	V_2O_5	As_2O_5	H_2O
1.	27·50	22·76	1·15	30·61	0·17	1·38	1·83	0·53	9·33	5·13 = 100·39
2.	27·84	24·22		26·70	....	3·01	2·17	9·20	2·76	5·01 = 100·91.

It is concluded by Bettendorff, that in this mineral arsenic and vanadium replace each other in varying proportions, with a consequent variation in color; in several other trials 1·83, 2·31, 2·53, 2·98, 6·64 p. c. As_2O_5 were found; v. Lasaulx (l. c.) shows that the vanadium ardennite is probably the original mineral, and that the presence of the arsenic is due to gradual alteration.

Arequipite.—*A. Raimondi*, Minéraux du Pérou, Paris, 1878, p. 167.

Compact, wax-like. H. nearly 6. Color honey yellow. Fracture conchoidal. According to a qualitative analysis, a silico-antimoniate of lead. B. B. on charcoal fuses with difficulty, yielding buttons of lead, and gives off antimonial vapors. Slightly attacked by nitric acid, dissolves slowly in hydrochloric acid to which a little nitric has been added, and leaves a residue of silica. Occurs sparingly in a quartzose gangue, with argentiferous lead carbonate and chrysocolla, at the Victoria mine, Montagne de la Trinité, near Tibaya, Province of Arequipa, Peru. [Needs further examination, probably a mixture.]

ARGENTOPYRITE, Min., p. 39; App. II., p. 4.—See *Sternbergite*, p. 115.

Argyropyrite.—See *Sternbergite*, p. 115.

ARITE.—App. II., p. 4.

Arrhenite.—*Nordenskiöld*; *Engström*, Inaug. Diss., Upsala, 1877 (Abstr. by Brögger, Z. Kryst., iii., 201, 1878).—A substance looking like red feldspar; occurs with fergusonite and cyrtolite at Ytterby, Sweden. G. = 3·68. Analysis: Ta_2O_5 21·28, Cb_2O_5 2·67, SiO_2 17·65, ZrO_2 3·42, Fe_2O_3 1·87, Al_2O_3 3·88, $Ce_2(Di_2, La_2)O_3$ 2·59, Y_2O_3 22·06, Er_2O_3 11·10, CaO 5·22, BeO 0·74, H_2O 6·87 = 100·35.

[Regarded as only a decomposition product, and hence not deserving of a distinct name.]

Arsenargentite.—*J. B. Hannay*, Min. Mag., i., 149, 1877. In orthorhombic acicular crystals imbedded in native arsenic. Analysis gave: As 18·43, Ag 81·37 = 99·80, corresponding to the formula Ag_3As. Source "probably Freiberg."

[An imperfect description from a single specimen of uncertain origin is a most unsatisfactory basis for a new name.]

ARSENIC, Min., p. 17; App. II., p. 5.—Cryst., anal. (Janovsky), Joachimsthal, *v. Zepharovich*, Ber. Ak. Wien, lxxi., 272, 1875.

ARSENIOSIDERITE.—Min., p. 76, App. II., p. 5.

ARSENOLITE, Min., p. 183.—Anomalous optical characters of artificial crystals, perhaps pseudo-isometric, *Grosse-Bohle*, Z. Kryst., v., 233, 1880. See also *Senarmontite*, p. 108.

ARSENOPYRITE, Min., p. 78; App. II., p. 5.—**Cryst.**, Joachimsthal, *Gamper*, Verh. geol. Reichs., 1876, 354. With pyrite in parallel position, *Sadebeck*, Wied. Ann., v., 576, 1878; do. with galenite, *Groth*, Min.-Samml., Strassburg, p. 39, 1878. Reichenstein, Silesia, *Hare*, Z. Kryst., iv., 296, 1879.

Arzruni (Z. Kryst., ii., 430, 1878) has examined (but see Hare l. c.) crystals from eight localities, and has shown considerable variation in angle between them. He also states that while the composition is different for different localities, it agrees neither with $FeS_2 + AsS_2$, nor with $mFeS_2 + nFeAs_2$, but that the percentage amount of iron remains nearly constant.

Becke (Min. Mitth., 1877, 101) discusses the relations in crystalline axes between arsenopyrite, danaite, and glaucodot, and concludes that they do not correspond with the amount of cobalt present, as suggested by Scheerer; this result, however, is questioned by Groth (Z. Kryst., ii., 520).

ARSENOTELLURITE.—App. II., p. 5.

ARSENSTIBITE.—App. II., p. 5.

ASMANITE, App. II., p. 5.—In meteoric iron of Rittersgrün, *Weisbach*, J. Min., 1876, 934; *Winkler*, ib., 1879, 903. According to Weisbach, asmanite is identical with tridymite, as suggested by *v. Lasaulx* (Z. Kryst., ii., 274, 1878). See in Nov. Act. Leopold.-Car. Ak., xl., 358, 1878. See also *Groth*, Tab. Uebers. Min., p. 33, 1882.

ASPIDOLITE.—App. I., p. 2, II., p. 5.

ASTEROITE.—App. I., p. 2.

ASTROPHYLLITE, Min., p. 308; App. II., p. 6.—With arfvedsonite and zirkon, El Paso Co., Colorado, *König*, Am. Phil. Soc., Philad., xvi., 509, 1877 (or Z. Kryst., i., 423). An analysis gave: SiO_2 34·68, TiO_2 13·58, ZrO_2 2·20, Fe_2O_3 6·56, Al_2O_3 0·70, FeO 26·10, MnO 3·48, Na_2O 2·54, K_2O 5·01, H_2O 3·54, MgO 0·30, CuO 0·42, Ta_2O_5 (?) 0·80 = 99·91.

Cryst. and optical exam., Norway and Colorado, *Bücking*, Z. Kryst., i., 433, 1877; *Brögger*, Z. Kryst., ii., 278, 1878. Brögger concludes that the mineral belongs to the triclinic system. It is now referred to the pyroxene group.

ATACAMITE, Min., p. 121; App. II., p. 6.—**Cryst.**, Chili, *Brögger*, Z. Kryst., iii., 488, 1879; *v. Rath*, Z. Kryst., v., 256, 1880.

Atelina, ATELITE.—See *Tenorite*, p. 119.

Atopite.—*Nordenskiöld*, Geol. För. Förh., iii., 376, 1877.

Isometric; in octahedrons, with cube and dodecahedron, also *m–m*, and *i–n* planes. H. = 5·5–6. G. = 5·03. Lustre greasy. Color yellow to resin brown. Translucent. Composition $R_2Sb_2O_7$ = Sb_2O_5 78·12, CaO 17·51, FeO 2·71, MgO 1·50, K_2O 0·84, Na_2O 4·32 = 100. Analyses: 1, the mineral fused with sodium carbonate; 2, do. reduced with hydrogen; 3, mean of (1) and (2).

	Sb_2O_5	FeO	MnO	CaO	K_2O	Na_2O		
1.	72·61	3·04	1·34	18·05	....	....		
2.	.....	2·54	1·72	17·65	0·86	4·40		
3.	72·61	2·79	1·53	17·85	0·86	4·40	=	100·04

B. B. in forceps in O. F. unchanged. On charcoal in R. F. sublimes in part, fuses at first with difficulty, and gives finally, when the antimony pentoxide is all reduced to the metallic state and driven off, a dark infusible slag. In salt of phosphorus dissolves to a clear bead, yellow while hot, and colorless on cooling. Insoluble in acids; decomposed with difficulty by fusion with sodium carbonate. Easily reduced by hydrogen. (cf. *romeite.*)
Occurs as octahedrons imbedded in hedyphane, which in turn forms little veins in rhodonite; rare. Locality Långban, in Wermland, Sweden. Named from *ἄτοπος, unusual.*

AUGITE.—See *Pyroxene*, p. 100.

AUTUNITE, Min., p. 586; App. II., p. 6.—Himmelfahrt mine, Johanngeorgenstadt, Saxony; *Brezina* makes the crystals to be monoclinic (or triclinic), with pseudo-tetragonal symmetry, Z. Kryst., iii., 273, 1879.

AZURITE, Min., p. 715; App. II., p. 6.—Cryst. descript. (twins), Chessy near Lyons, *Groth*, Min.-Samml., Strassburg, p. 138, 1878.

BABINGTONITE, Min., p. 227; App. II., p. 6.—Observed in slag from Bessemer steel, *Klemm*, Chem. Centralbl., 1874, 215. See also *Szaboite*, p. 118.

Balvraidite.—*Heddle*, Min. Mag., iv., 117, 1880.
Structure saccharoidal. H. = 6. G. = 2·905–2·908. Color pale purplish brown. Analyses (1) dark var.; (2) paler var.:

SiO_2	Al_2O_3	Fe_2O_3	MnO	MgO	CaO	Na_2O	K_2O	H_2O	
46·04	20·11	2·52	0·79	8·80	13·47	2·72	1·36	4·71	= 100·02.
46·17	20·95	1·86	0·84	7·36	13·25	3·25	1·56	4·90	= 100·14.

B. B. fuses with intumescence to a vesicular pale blue glass. Presents a mottled appearance under the microscope, and was judged to be homogeneous. Occurs in a granular limestone, at Balvraid, Inverness-shire, Scotland. [Needs further examination; as the description stands at present, this substance, "which may prove to be a new mineral," certainly does not deserve a distinct name.]

Barcenite.—*J. W. Mallet*, Am. J. Sc., xvi., 306, 1878.
Massive; structure finely granular, compact or porous; also columnar (pseudomorphous after livingstonite). H. = 5·5. G. = 5·343. Lustre dull, earthy, sometimes slightly resinous. Color, dark gray, nearly black. Streak ash gray, with slight greenish tint. Fracture tolerably even. Brittle. Analysis by J. R. Santos:

Sb*	S	Hg	Ca	O	H_2O	
50·11	2·82	20·75	8·88	[17·61]	4·73 (below 130°C. 1·23)	SiO_2 0·10 = 100.

* Atomic weight = 120.

The sulphur is assumed to exist as HgS, and is accordingly deducted with a corresponding amount of mercury. For the remainder the following atomic ratios are then obtained:—RO : Sb_2O_3 : Sb_2O_5 = 4 : 1 : 5, and Sb_2O_5 : H_2O = 1 : 5. The antimonic acid (Sb_2O_5. 5 H_2O) is again assumed to exist independently as an impurity, and the formula for the remainder written: [Sb_2O_3 4(RO)] $(Sb_2O_5)_5$ corresponding to a normal antimonate $\dot{M}SbO_3$.
B. B. in O. F. decrepitates slightly, turns nearly white, and becomes rounded on the edges; in R.F. gives off antimony fumes, accompanied with a greenish blue flame. In

the closed tube gives off water, metallic mercury, black mercury sulphide, and a little antimony trioxide; in the open tube metallic mercury is deposited, and also more antimony trioxide, the fumes of sulphur dioxide passing off. On charcoal a white antimonial sublimate, and with soda antimony is obtained in metallic beads. With borax in O. F. a clear colorless glass, which in R.F. becomes turbid.

From Huitzuco, State of Guerrero, Mexico. Associated with livingstonite, from the decomposition of which it has been formed. Named after Sr. Mariano Barcena, the Mexican mineralogist. [That the original material examined is, as assumed, a mixture, cannot be questioned, but that the true nature of the compounds present has been, or in fact can be, definitely settled so as to establish beyond doubt the nature of a new species seems very improbable.]

Barsowite, Min., p. 340.—Re-examined microscopically by *Bauer* and analyzed by *Friederici*, and shown to have the composition of anorthite, with which it does not, however, in all respects correspond; G. = 2·584 after deduction for the corundum present, J. Min., 1880, ii., 63.

Bartholomite.—App. II., p. 6.

Barylite.—*C. W. Blomstrand*, Geol. För. Förh., iii., 128, 1876.

In groups of prismatic crystals, more or less tabular in habit. Two distinct cleavages forming an angle of about 84°. H. = 7. G. = 4·03. Lustre greasy. Colorless. Semi-transparent. Analysis:

	SiO_2	Al_2O_3	Fe_2O_3	BaO	PbO	CaO	MgO	CuO	Bi_2O_3	ign
$(\frac{2}{2})$	34·36	16·02	0·98	46·23	0·93	0·68	0·27	0·09	0·19	0·15 = 99·90.

Formula calculated: $Ba_4[Al_2]_2Si_7O_{24}$, which requires: SiO_2 33·94, Al_2O_3 16·61, BaO 49·45 = 100. B. B. infusible; not attacked by acid. Named from *βαρύς heavy*, and *λίθος stone*. Occurs with hedyphane in crystalline limestone at Långban, in Wermland, Sweden. [A mineral of so unusual composition deserves to be more thoroughly described on the crystallographical side.]

Barytocalcite, Min., p. 701.—**Anal.** (by Lundström), corresponding to $CaCO_3 + BaCO_3$, Långban, Sweden, *Sjögren*, Geol. För. Förh., iii., 289, 1876. According to Des Cloizeaux (Bull. Soc. Min., iv., 95, 1881), the mineral analyzed by Lundström is rhombohedral with a cleavage angle of about 105°.

Barytocelestite.—See *Celestite*, p. 21, and App. II., p. 7.

Baryturanite = *Uranocircite*, p. 127.

Bastite, Min., 469.—Anal., Elba, *Pisani*, C. R., lxxxiii., July 10, 1876.

Bastnäsite.—See *Tysonite*, p. 126, and App. I., p. 2.

Beauxite, Min., p. 174; App. II., p. 7.—**Analyses**, Feistritz and Nassau, showing wide variation in composition, *Henatsch*, Inaug. Diss., Breslau, 1879 (Z. Kryst., iv., 642, 1880). Age, origin, etc., *Dieulafait*, C. R., xciii., 804, 1881.

Beccarite.—See *Zirkon*, p. 134.

Beegerite.—*König*, Am. Chem. Journ., ii., 379, 1881 (or Z. Kryst., v., 322).
Isometric, in elongated crystals; also massive. Cleavage cubic. G. = 7·273. Color light to dark gray. Lustre brilliant metallic. Mean of 4 partial analyses, after deduction of quartz (2·6 p. c.):

S	Bi	Pb	Cu
14·97	20·59	64·23	1·70 = 10·49.

This corresponds nearly to $Pb_6Bi_2S_9$ or $6PbS + Bi_2S_3$ = S 14·78, Bi 21·36, Pb 63·84. B. B. decrepitates, giving on charcoal reactions for lead and bismuth. Dissolves readily in warm HCl. From the Baltic Lode, near Grant P. O., Park Co., Colorado. Named after Mr. Hermann Beeger, of Denver.

BERAUNITE—ELEONORITE, *Nies*, xix. Ber. Oberhess. Ges. Nat.-u. Heilk., p. 111, 1880. *Streng*, J. Min., 1881, i., 102.
Monoclinic crystals, tabular (*i-i*) and prismatic (in direction of *b*), in habit similar to some crystals of lazulite from Georgia. Axes $\grave{c} : b : \grave{a}$ = 4·0157 : 1 : 2·755, β = 48° 33′. *O* ∧ *i-i* = 131° 27′, *i-i* ∧ 1 = 104° 24′; 1 ∧ 1 (clinodiag.) = 89° 56′. Twins with *i-i* as twinning plane, also penetration twins. Cleavage *i-i*. Often in druses, and in radiated foliated crusts (Streng). H. = 3–4. Lustre vitreous, on *i-i* inclining to pearly. Color red brown to dark hyacinth red. Streak yellow, strongly dichroic.
Analyses by Streng: 1, crystals; 2, radiated coating on limonite:

	P_2O_5	Fe_2O_3	H_2O
1.	31·88	51·94	16·37 = 100·19.
2.	31·78	52·05	16·56 = 100·39.

Formula $[Fe_2]_3P_4O_{19}, 8H_2O$, or $2[Fe_2]P_2O_8 + [Fe_2]H_6O_6 + 5$ aq. B. B. fuses easily to a black bead metallic in appearance, crystalline on cooling. Easily soluble in HCl. Occurs on limonite at the Eleonore mine on the Dünsberg, near Giessen, and at the Rothläufchen mine near Waldgirmes, in the same region.

Streng (l. c.) calls attention to the close relation of eleonorite to beraunite from St. Benigna, Bohemia (Min., p. 558). The following are analyses of the original beraunite: 1. Tschermak, Ber. Ak. Wien, xlix., 341, 1864; 2, 3. Boricky, ib., lvi., 11, 1867; 4. Frenzel, from Scheibenberg, Saxony, J. Min., 1873, 23.

	P_2O_5	Fe_2O_3	H_2O
1. St. Benigna	30·5	55·0	14·0 Na_2O 1·5 = 101.
2. "	30·2	55·8	15·1 = 101.
3. "	28·99	55·98	14·41 = 99·38.
4. Scheibenberg	28·65	54·50	16·55 = 99·70.

Streng shows that in composition the St. Benigna mineral is nearly identical with eleonorite, but regards the differences in physical characters too great to allow of their being united. The mineral of Frenzel seems to have a different crystalline form.

Bertrand (Bull. Soc. Min., iv., 88, 1881), has subjected both the beraunite and eleonorite to a new examination, and concludes that in angles, dichroism and optical qualities they are the same. There would seem consequently to be little doubt of their identity.

Bergamaskite.—See *Amphibole*, p. 5.

Bernardinite.—Described as a new fossil resin from San Bernardino, Cal., by *J. M. Stillman* (Am. J. Sc., III., xviii., 57, 1879); since shown by him to be an exudation from a species of conifer, which has received its particular characters from exposure to the atmosphere (ib., xx., 93, 1880).

BERYL, Min., p. 245; App. II., p. 7.—**Cryst.**, Eidsvold, Norway, *Websky*, Min. Mitth., 1876, 117. Alexander Co., N. C., *Hidden*, Am. J. Sc., III., xxi., 159; xxii., 24, 1881.

Santa Fé, Bogota, New Granada, *Vrba*, Z. Kryst., v., 430, 1881. Gold sands of the Ural, *N. v. Kokscharof, Jr.*, Bull. Ac. St. Pet., xxvii., 85, 1881 (or Min. Russl., viii., 223).

Pyro-electrical properties, *Hankel*, Pogg. Ann., clvii., 161, 1876. Specific gravity of different specimens, *Church*, Geol. Mag., II., ii., 320, 1875.

Occurrence of emeralds of unusual size (one crystal 10 inches long) and beauty of color, in Alexander Co., N. C., *Hidden*, Am. J. Sc., xxii., 489, 1881.

Mallard (Ann. Min., VII., x., 148, 1876) describes the optical anomalies observed in crystals of beryl, and concludes that it is *pseudo-hexagonal*, the individuals of which a crystal is made up being orthorhombic; the relations are regarded as similar to those in apatite. See also *Des Cloizeaux*, Bull. Soc. Min., iv., 94, 1881.

Atterberg (Geol. För. Förh., ii., 405, 1874) uses the name PSEUDO-EMERALD (pseudosmaragd) to designate a mineral resulting from the alteration of beryl. The name was introduced by Berzelius for pseudomorphous crystals, consisting, as he regarded it, of ordinary beryl and mica. Atterberg retains the name for the hard portion of similar pseudomorphs, which, however, he finds to be not true beryl. Its characters are: hardness 5·5 ; G. = 2·70 ; lustre waxy; color dark grayish green ; fracture splintery. Intimately mixed with mica scales. Analyses : 1, 2, the latter on material not entirely free from mica :

	SiO_2	Al_2O_3	BeO	FeO	MgO	K_2O	H_2O	
1.	57·32	17·46	13·11	0·30	0·32	7·82	3·64	= 99·97.
2.	56·23	19·05	12·55	0·18	0·50	7·45	4·83	= 100·79.

If the water is considered basic, the ratio for bases to silica is 2 : 3. The mineral differs from ordinary beryl in having lost part of its silica and gained potash and water; the alumina and glucina are sensibly unchanged. From Kårarfvet, near Fahlun, Sweden.

Grattarola (Riv. Scientif.-industr., No. 19, 1880, Florence) has given the name ROSTERITE to a mineral which he regards as a distinct variety of beryl. It occurs in short prismatic to tabular doubly-terminated crystals. Basal plane rounded, and apparently formed of many planes of varying position, belonging to the second series. In polarized light a basal section is divided into six sectors, corresponding to the prismatic edges, for the three alternate of which the extinction is the same. Biaxial interference figures (angle 15°) observed, the extinction plane in part parallel to the prism, in part inclined from 3½° to 7°. Color pale rose red. Analyses : 1, 2, from the respective ends of a crystal, which had a nucleus of normal beryl (anal. 3) ; 4, "typical rosterite."

		SiO_2	Al_2O_3	BeO	MgO	CaO	Na_2O, K_2O	Li_2O	H_2O	
1.	G. = 2·77	61·97	21·93	8·62	1·26	0·42	undet.	....	undet.	
2.	G. = 2·74	60·26	21·18	9·71	1·57	2·55	undet. 0·58	tr.	3·07	= 98·92
3.	G. = 2·77	62·88	17·09(?)	15·97(?)	2·62	2·99	undet.	....	2·32	= 103·87.
4.	G. = 2·75	61·34	23·20	8·81	0·50	2·19	1·00	....	2·03	= 99·07.

[The reasons for regarding this as a distinct variety of beryl are: its crystalline habit, its optical character, and the variation in chemical composition. To the first, however, no weight can be given, and as little to the second, since analogous optical anomalies have been previously observed in ordinary beryl ; as to the composition, further careful analyses are needed to establish that point.] Locality, Island of Elba.

BERZELIITE, Min., p. 544.—*W. Lindgren* (Geol. För Förh., v., 552, 1881) states that the hitherto accepted description of berzeliite is incorrect, in consequence of its having been confounded with another mineral which occurs at Långban, associated with it. The characters of true berzeliite are :

Massive ; isometric (Sjögren, Geol. För. Förh., ii., 533, 1875, and A. Wichmann, Z. Kryst., v., 105, 1880) ; no distinct cleavage. H. = 5. G. = 4·07–4·09. Lustre resinous. Color honey yellow to sulphur yellow. Transparent to translucent. Fracture semi-conchoidal. Brittle. B. B. fuses rather easily to a brown bead. Soluble in hydrochloric and nitric acids. Occurs imbedded in small grains in a granular calcite ; with calcite in hausmannite and in braunite; with caryinite. Sometimes of a green color, from minute inclosed hausmannite crystals.

There also occurs at Långban another arsenate, having the following characters : Massive ; anisotrope, but crystalline system uncertain ; no distinct cleavage. H. = 5. G. = 4·03–4·04 ; 3·89. Color dirty yellowish white or light sulphur yellow. An analysis by L. W. McCay gave : As_2O_5 62·00, CaO 20·00, MgO 12·81, MnO 4·18, PbO, FeO tr., insol. (SiO_2) 0·68 = 99·67 ; this corresponds to a simple ortho-arsenate, $R_3As_2O_8$. Occurs massive in a light brown fine granular mixture of calcite and manganiferous mica, often penetrated by hausmannite. This mineral is regarded as the one to which the earlier descriptions belong (Min., p. 541), but while optically distinct from berzeliite, their true relation is still very uncertain.

[The above observations only increase the doubts as to the true nature of berzeliite; as possibly bearing upon the question as to the relation of the isotrope and anisotrope minerals mentioned, attention may be called to the fact that Des Cloizeaux has observed isotropic varieties of gadolinite and also of homilite, supposed to be due to alteration.]

See also *Caryinite*, p. 20.

Beudantite, Min., p. 589.—Optical exam., the same characters belong to the beudantite of Horhausen, of Cork (Adam's corkite), and of Dernbach (Adam's dernbachite); *Bertrand*, Bull. Soc. Min., iv., 255, 1881.

Beyrichite.—App. I., p. 8.

Bhreckite (or **Vreckite**), *Heddle*, Min. Mag., iii., 57, 1879. Fine granular, scaly ; soft and friable. Occurs as a light apple-green coating on quartz crystals. An analysis gave : SiO_2 34·92, Al_2O_3 7·16, Fe_2O_3 12·71, FeO 2·11, MnO 0·41, CaO 16·08, MgO 8·26, H_2O 17·77 (1·03 at 100° C.) = 99·42 (alkalies in traces). Soluble in HCl. From a cavity in a bowlder of syenitic granite, found on the hill of Ben Bhreck, near Tongue, in Sutherland, Scotland. [Provisionally named on the ground that "the substance may prove to be a new mineral"—needs further examination. No sufficient proof of the homogeneity of the material analyzed is given.]

Bieirosite.—App. II., p. 7.

Bindheimite, Min., p. 591.—**Anal.**, Sevier Co., Ark., *Dunnington*, Amer. Assoc., 1877, 182; *C. E. Wait*, Trans. Am. Inst. Min. Eng., viii., 50, 1880.

Bischofite.—See *Chloromagnesite*, p. 25.

Bismite, Min., p. 785 ; App. II., p. 7.

Bismuth, Min., p. 19; App. II., p. 7.—**Cryst.**, Schneeberg, *Fletcher*, Phil. Mag., V., ix., 185, 1880.

Anal. (with galenite), Mossgrufva, Nordmark, *Sjögren*, Geol. För. Förh., iv., 106, 1878.

Bismuthinite, Min., p. 30 ; App. II., p. 7.—**Cryst.**, Tazna, Bolivia, *Groth*, Z. Kryst., v., 252, 1880.

Anal., Choroloque, Bolivia, *Domeyko*, 6th App. Min. Chili, p. 22, 1878.

Bismutite, Min., p. 716 ; App. II., p. 7.—*Weisbach* (Jahrb. Berg.-Hutt., 1877) has described a supposed new bismuth carbonate under the name of BISMUTOSPHÆRITE.—Occurs in spherical forms with concentric structure, fine fibrous, radiated. H. = 3. G. = 7·28–7·32. Color bright yellow to blackish brown, different in successive layers. Streak yellowish gray. An analysis gave *Winkler* : CO_2 8·97, Bi_2O_3 88·58, quartz 0·98 = 97·83. Formula calculated Bi_2CO_5 (= $Bi_2C_3O_9$ + $2Bi_2O_3$), which requires CO_2 8·66, Bi_2O_3 91·34 = 100 [but uncertain, as the analysis shows a considerable loss] ; found at Neustädtel, near Schneeberg, Saxony. Weisbach states that this mineral is the original *Arsenik-wismuth* of

Breithaupt; Frenzel previously described what he regarded as Breithaupt's mineral under the name of agricolite (App. II., p. 1).

Other analyses of bismuth carbonates have been made by Carnot (C. R., lxxix., 304, 1874) of the mineral from Meymac, Corrèze, he found Bi_2O_3 86–90 p. c., CO_2 3·14–6·43, H_2O 1·94–4·86. He distinguishes three types: 1 (anal. 1), grayish white, somewhat foliated; 2 (anal. 2), dark gray, slightly greenish, fibrous; 3 (anal. 3), white, earthy, with yellowish spots. Anal. 4 by *Frenzel* (J. Min., 1873, 801, 946), from San Luis Potosi, Mexico (see also Barcena, Rev. Cientif. Mex., i., 8, Dec., 1879). Anal. 5 by Liversidge, with stream tin from Pond's Creek, New South Wales (Proc. Roy. Soc. N. S. W., Nov. 3, 1880). Anal. 6 by Winkler, quoted by Weisbach (J. Min., 1880, ii., 112), from Neustädtel, G. = 6·12–6·27, pseudomorph after native bismuth.

		CO_2	Bi_2O_3	H_2O	PbO	FeO	CaO	MgO	As_2O_5	Sb_2O_5	SO_3	HCl	gangue	
1. Meymac,	G. = 6·94	3·74	89·75	2·76	0·55	0·58	0·35	tr.	0·78	0·57	0·25	0·37	0·20	= 99·80.
2. "	G. = 7·26	4·15	87·50	3·55	0·44	0·50	0·55	0·07	0·80	1·25	0·22	0·20	0·30	= 99·53.
3. "	G. = 7·08	5·35	86·90	3·02	0·40	0·43	0·38	0·05	0·65	1·20	0·13	0·14	1·10	= 99·75.
4. San Luis,	G. = 7·59	7·00	90·10	1·80, SO_3 0·27, gangue 0·30 = 99·47.										
5. Pond's Creek		5·43	76·06	[11·84], SiO_2 4·69, Al_2O_3 (Fe_2O_3 tr.) 1·98 = 100.										
6. Neudstädtel,	G. = 6·20	2·91	95·90	1·04 = 99·85.										

[These analyses show a wide variation, due chiefly, without doubt, to the impurity of the material analyzed. Frenzel's mineral is rather near the bismutosphærite of Weisbach, which last seems to be distinct from the other minerals; if the loss (see anal.) is not water, it is an anhydrous carbonate.]

The bismuth carbonate described by Vogl as occurring at Joachimsthal (Min., p. 717, 753 A), since called WALTHERITE, includes, according to Bertrand (Bull. Soc. Min., iv., 58, 1881) two species, the one brown, the other green, optically unlike.

BISMUTOFERRITE.—App. I., p. 3; II., p. 7.

Bjelkite.—See *Cosalite*, p. 31.

Blackmorite.—See *Opal*, p. 86.

BLENDE.—See *Sphalerite*, p. 111.

BLÖDITE, Min., p. 643; App. II., p. 8.—Cryst., Pendschab, India, *Schimper*, Z. Kryst., i., 71, 1877.

Occurrence at Ischl, Min. Mitth., 1877, 97.

Blomstrandite. *Lindström*, Geol. För. Förh., ii., 162, 1874.

Massive. H. = 5·5. G. = 4·17–4·25. Lustre vitreous. Color black. Powder coffee brown. Opaque, only translucent in very thin splinters.

Analyses:

	Cb_2O_5	Ta_2O_5	TiO_2	UO	FeO	CaO	H_2O	
1.	49·76		10·71	23·68	3·33	3·45	7·96,	MgO 0·16, Al_2O_3 0·11, MnO 0·04, precip. by H_2S 0·12 = 99·32.
2.	60·77			23·37	3·39	3·04	8·17,*	MgO tr. MnO 0·06, precip. by H_2S 0·20 = 99.

* At 100° 2·78 (in another trial 2·65), above 100° 5·39.

The atomic ratio of R : Cb, Ti = 1 : 2·5, and for Ti : Cb = 1 : 3·75. B. B. fuses with difficulty. Gives off water in the closed tube. With borax in O. F. a reddish yellow, on cooling a yellow bead; in R. F. reddish brown. With salt of phosphorus in O. F. a red brown bead when hot, and yellow when cold; in R. F. reddish yellow hot, and green cold.

Found very sparingly with nohlite (App. II., p. 41) in a feldspar quarry, at Nohl, Sweden. Named for Prof. C. W. Blomstrand of Lund. [Apparently distinct from other known minerals of this group, but needs further examination.]

Bolivite. *Domeyko*, 6th App. Min. Chili, p. 19, 1878. Described in some detail as a bismuth oxysulphide, Bi_2O_3 with Bi_2S_3. It is derived from the oxidation of the sulphide bismuthinite, and is of very uncertain composition. The description would apply to a mixture of the oxide with the original sulphide, which is enclosed in it, and it is very improbable that they are in chemical combination. The uncertain character of the mineral seems to have been later accepted by Domeyko, for in the 3d Ed. of his Mineralogy (1879, p. 304) the occurrence is only mentioned briefly, and without any name. Locality, mines of Tazna, in the province of Choroloque, Bolivia.

BOMBICCITE.—App. II., p. 8.

BORACITE, Min., p. 595; App. II., p. 8.—The question as to the true explanation of the long recognized "optical anomalies" of boracite has been recently discussed by *Mallard*, Ann. Min., VII., x., 93, 1876; and Bull. Soc. Min., ii., 147; *E. Geinitz*, J. Min., 1876, 484; 1877, 394; *Baumhauer*, Z. Kryst., iii., 337, 1879; *Klein*, J. Min., 1880, ii., 209; 1881, i., 239.

Geinitz shows that (contrary to the earlier explanation) unaltered boracite is anisotropic; Mallard makes the species pseudo-isometric, explaining the optical phenomena by the grouping of twelve orthorhombic individuals (as remarked by Klein this hypothesis was proposed by Hartmann in 1826). Baumhauer reaches a conclusion somewhat similar to that of Mallard on the basis of the results of etching experiments. Klein, however, seems to settle the question conclusively in favor of the true isometric character of the species. He shows, for example, that the interior optical structure does not correspond to the exterior planes; that the distribution of the etching figures does not depend on the interior optical limits; and further, that upon an increase of temperature the former optical limits disappear or become indistinct, and that the optical fields change their position without affecting the form of the etching figures. He concludes that all the optical anomalies can be explained by the internal tension produced in the course of the growth of the crystal.

BOWENITE, Min., p. 465.—From New Zealand, *Berwerth*, Ber. Ak. Wien, lxxx., 116, 1879.

Bowlingite. *J. B. Hannay*, Min. Mag., i., 154, 1877.

Massive, consisting of minute crystals. Soft, feel like steatite. G. = 2·282–2·290. Color deep green. In thin sections semi-transparent. Analyses: 1, 2, 3, 4, Hannay; 5, Young, Trans. Geol. Soc. Glasgow, ii., 212:

			SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	$CaCO_3$	H_2O	
1.	Bowling	G. = 2·282	34·32	18·07	3·65	6·81	9·57	5·14	22·70	= 100·26.
2.	"		35·08	16·85	3·92	6·95	10·22	4·89	21·85	= 99·76.
3.	Cuthbin	G. = 2·29	35·66	15·09	5·22	7·02	12·41	5·02	19·89	= 100·31.
4.	"		35·82	16·14	4·85	6·99	11·73	4·87	19·63	= 100·03.
5.	Cathcart		31·95	15·40	....	21·40	20·95	4·30	[6.30]	= 100·00.

Analysis 5, by Young, is said to have been made on the same material as that examined by Hannay! Found at Bowling, near Dumbarton, on the Clyde, and from the Cuthbin hills, Scotland, where it forms little veins in dolerite, being intimately associated with chrysolite, from which it may have been formed. Heddle (Trans. Soc. Edinb., xxix., 97, 1879), gives two analyses of the original mineral, of which the following is one: SiO_2 38·08, Al_2O_3 6·26, Fe_2O_3 4·36, FeO 4·97, MnO 0·23, CaO 2·97, MgO 21·46, K_2O 0·95, Na_2O 0·11, H_2O 20·48 = 99·97 (H_2O at 100°, 12·31). He concludes that Hannay's analyses were erroneous, and that the mineral is really a saponite. [The describer suggests a doubt as to the purity of the original material, which is a suggestion the accuracy of which no one will question.]

Brackebuschite.—See *Des Cloizite*, p. 36.

Braunite, Min., p. 163.—**Anal.**, Nagpur, India, *F. R. Mallet*, Rec. Geol. Surv. India, xii., 73, 1879. See also *Pyrolusite*, p. 99.

Bravaisite. *E. Mallard*, Bull. Soc. Min., i., 5, 1878.
Orthorhombic (on optical grounds); in thin layers and schistose masses consisting of fine crystalline fibres, mostly parallel in position. H. = 1–2. G. = 2·6. Color gray to greenish gray. Double refraction negative, strong; 2 E_a = 40°. Unctuous to the touch. Paste-like when wet. Analysis:

SiO_2	Al_2O_3	Fe_2O_3	CaO	MgO	K_2O	H_2O
51·4	18·9	4·0	2·0	3·3	6·5	13·3 = 99·4.

The formula deduced, after the deduction of the iron as due to the presence of pyrites, is $R_2[Al_2]_2Si_9O_{26} + 8$ aq. B. B. fuses easily to a white glass. In the closed tube gives off water and becomes brown. Partially attacked by acids. Found in layers in the coal and bituminous schists of Noyant (Allier Dept.), France. Named after the French crystallographer M. Bravais. [Near some varieties of glauconite.]

Breislakite, Min., p. 216. According to *v. Lasaulx* (J. Min., 1878, 380), to be referred to amphibole instead of to pyroxene.

Breunnerite, Min., p. 686.—**Cryst.**, *v. Kokscharof*, Min. Russl., vii., 181, 221, 1878.

Brochantite, Min., p. 664; App. II., p. 9.—**Optical properties determined** (orthorhombic?), *Bertrand*, Bull. Soc. Min., iii., 56, 1880.
From Pisco, Peru, anal. by Mannington, *Semmons*, Min. Mag., iv., 259, 1881.
Made artificially, *Meunier*, C. R., lxxxvi., 686, 1878.

Bronzite, Min., p. 208; App. II., p. 9.—**Anal.**, Dun Mt., New Zealand, *Hilger*, J. Min., 1879, 129.

Brookite, Min., p. 164; App. II., p. 9.—*Mallard* (Ann. Min., VII., x., 134, 1876) regards the three forms of titanium dioxide—brookite, octahedrite, and rutile—as having the same primitive form (monoclinic), and argues that the differences between the species in the forms of the crystals and in physical characters, are due to the different ways in which the individuals are grouped together. *Schrauf* (Ber. Ak. Wien, lxxiv., 535, 1876), after an extended study of crystals from different localities, concludes that they are all monoclinic and isomorphous with wolframite; he, however, distinguishes among them three types varying in the crystallographic constants (this result was announced earlier, see App. II., p. 9; also J. Min., 1877, 800; 1878, 50). Later (Z. Kryst., i., 274, 1877) he discusses the optical characters of the species in their relation to the crystalline system. The conclusions of Schrauf are questioned by *Groth* (Min.-Samml. Strassburg, 109, 1878), and measurements by Bücking are quoted agreeing with the orthorhombic form. Vom Rath earlier (Pogg. Ann., clviii., 405, 1876) found crystals from Atliansk to be orthorhombic.
See also *Pseudobrookite*, p. 97.

Brucite, Min., p. 175; App. II., p. 9.—Pyro-electrical properties, *Hankel*, Wied. Ann., vi., 53, 1879. Calculation of the indices of refraction by a method based upon the measured diameters of the rings observed in the axial interference figures in a plate of known thickness, *Bauer*, Ber. Ak. Berlin, 1881, 958.

An anal. of a partially decomposed brucite from Siebenlehn, near Freiberg, gave Petersen: MgO 38·92, FeO 18·73, CO_2 7·38, H_2O 30·46, SiO_2 4·15, Al_2O_3, CaO tr. = 99·64. After deducting the SiO_2 as quartz, and 24·49 p. c. hydromagnesite believed to be present as a decomposition product, and after calculating the remainder to 100, the result is MgO 39·89, FeO 24·92, H_2O 35·19 = 100. This is called EISENBRUCIT. *Sandberger*, J. Min., 1880, ii., 288.

Bunsenin.—See *Krennerite*, p. 66.

Thermo-electric properties investigated, *Hankel*, Pogg. Ann., clvii., 156, 1876. On the relation between the different crystalline forms, *Scharff*, Abhandl. Senck. Ges., x., 1876; Jahresb. Senck. Ges., 1879–80, p. 113.

Långban, Sweden, anal., $CaCO_3$ 87·14, $MnCO_3$ 10·06, $BaCO_3$ 2·04 = 99·24, *Sjögren*, Geol., För. Förh., iv., 111, 1878. Lindgren found 1·09 p. c. $ZnCO_3$ in calcite from Långban, ib., v., 557, 1881. Anal. of so-called onyx from Tecali, Mexico, *Damour*, C. R., lxxxii., 1085, 1876; *Barcena*, Proc. Am. Nat. Sc. Phil., 1876, 166. Analyses of calcite and other rhombohedral carbonates, *Heddle*, Trans. Acad. Ed., xxvii., 493, 1876.

"Isomorphism" with soda nitre and relation to the other rhombohedral carbonates discussed, *Tschermak*, Min. Petr. Mitth., iv., 99, 1881.

See also *Thinolite*, p. 51.

Calcozincite. *Shepard*, Contrib. Min., Amherst, 1876 (Am. J. Sc., III., xii., 231). A substance described as having a fine granular to columnar structure, light orange yellow color. H. = 3·5. G. = 3·95. Anal.: ZnO 81·00, CaO 7·56, CO_2 5·80, H_2O 4·26, MnO tr. = 98·62. Effervesces slightly with acid. From Stirling Hill, New Jersey. [5·8 CO_2 requires CaO 7·4 for $CaCO_3$—the substance is doubtless a mechanical mixture of zincite and calcite.]

Caledonite.—Min., p. 625; App. II., p. 10.

Callainite.—See *Variscite*, p. 128.

Calomel, Min., p. 111.—Cryst., El Doctor, Mexico, *Websky*, Ber. Ak. Berlin, 1877, 461.

The occurrence of native corrosive sublimate ($HgCl_2$) is reported by Besnou near Iquique, in the desert of Atacama; the determination, however, was baced only on some qualitative trials, Assoc. Franc. Adv. Sc., 1878, 533.

Calvonigrite.—See *Pyrolusite*, p. 99.

Cancrinite, Min., p. 329; App. II., p. 10.—*Rauff* (Z. Kryst., ii., 456, 1878) has subjected the original cancrinite of Miask to a thorough microscopic and chemical examination, and *A. Koch* (J. Min. Beil. Bd., i., 144, 1880) has done the same for that occurring in the syenite of Ditró, Transylvania. Both show that there is every reason, both as regards the physical characters and the constancy of chemical composition, to consider the mineral as an original species, and not as a decomposition product arising from the action on nephelite of a carbonated solution. The observations of Koch on the behavior of a thin section, when treated with HCl, are especially conclusive as showing that the CO_2 is present, not as calcite mechanically mixed, but as a true element in the composition of the silicate. Analyses: 1, Rauff; 2, Koch:

	SiO_2	Al_2O_3	Fe_2O_3	CaO	Na_2O	K_2O	CO_2	H_2O	
1. Miask, G. = 2·450, (⅔)	37·28	28·20	0·44	6·95	17·75	0·20	6·16	4·03	= 101·01.
2. Ditró	38·58	28·72	tr.	5·24	12·22	5·23	8·78		= 98·77.

The formula deduced by Rauff is $Na_8[Al_2]_4Si_9O_{34} + 2Ca(Na_2)CO_3 + 3H_2O$, and that of Koch for the Ditró mineral is $Na_6K_2[Al_2]_5Si_{11}O_{41} + 2Ca(Na_2)CO_3 + 4H_2O$. Rauff finds the ratio in the carbonate of Ca : Na_2 = 8 : 1, and Koch 7 : 1.

Carbonyttrine.—App. II., p. 10.

Carnallite.—Min., p. 113; App. II., p. 10.

Carpholite, App. II., p. 10; Min., p. 419.—Anal., Meuville, Ardennes, *de Koninck*, Bull. Ac. Belg., II., xlv., 15, 1878; xlvii., 564, 1879.

Caryinite. *C. H. Lundström*, Geol. För. Förh., ii., 178, 223, 1874.

Massive. H. = 3–3·5. G. = 4·25. Lustre greasy. Color brown to yellowish brown. Streak yellowish white. Fracture splintery. Analysis:

As_2O_5	PbO	MnO	FeO	CaO	MgO	CO_2	Cl	insol.	
47·17	10·52	15·82	0·54	16·40	4·25	3·86	0·07	0·65	= 99·28.

This corresponds, though only approximately, to the general formula $R_3As_2O_8$, after deducting the calcium carbonate. B. B. fuses easily to a black slag, giving reactions for arsenic, lead, and manganese. Dissolves readily, with slight effervescence in nitric acid. Occurs intimately mixed with calcite and hausmannite, at Långban, Wermland, Sweden. Named from *καρύινος*, *nut-brown*. *Sjögren* remarks that berzeliite occurs with caryinite, and sometimes enclosing it. He finds the berzeliite isotropic (isometric), and the caryinite anisotrope (monoclinic ?), and as the two species have analogous composition, he suggests that the former may have been formed from the latter (Geol. För. Förh., ii., 533, 1875). Lindgren (ib., v., 556, 1881), however, describes the way in which the minerals occur together, and concludes, for certain cases, that the caryinite is altered into berzeliite. [The genetic relation between caryinite and berzeliite merits further examination.]

According to *Des Cloizeaux* (Bull. Soc. Min., iv., 56, 1881), the mineral has two cleavages, at an angle of 130°. 2E = 41° 58′ to 47°. Dispersion $\rho > v$, also horizontal (hence monoclinic).

CASSINITE.—See *Feldspar Group*, p. 45.

CASSITERITE, Min., p. 157; App. II., p. 10.—**Cryst.** monograph, with a list of all observed planes, also analysis, *Becke*, Min. Mitth., 1877, 244. *Groth*, Min.-Samml., Strassburg, p. 104, 1878. Schlaggenwald, *v. Zepharovich*, Lotos, 1880.

CASTILLITE. Not castillite of Rammelsberg (Min., p. 46), but synonym of guanajuatite (q. v., p. 53), *Domeyko*, Min. Chili, 3d Ed., p. 310, 1879.

CASTORITE.—See *Petalite*, p. 91.

CELADONITE, Min., p. 463.—Analyses, in igneous rocks of Scotland, *Heddle*, Trans. Roy. Soc. Ed., xxix., 102, 1879.

Celestialite. *J. Lawrence Smith*, C. R., lxxxi., 1055, 1875. On treating the graphite from the interior of the meteoric iron of Sevier, Tenn., with ether, Smith obtained small quantities of acicular crystals having a peculiar odor, mixed with some small rounded points. These he regards as identical with crystals obtained from the iron of Alais, France (Mar. 15, 1806), by Roscoe (Proc. Lit. Phil. Soc. Manchester, iii., 57, 1863). Smith has obtained the same crystals from the Alais meteorite. In the closed tube he finds that they fuse at 115°–120°, and at a higher temperature the sulphur is sublimed, and a black residue left behind. He regards these crystals as proof of the presence of a sulpho-hydrocarbon, for which he proposes the name CELESTIALITE. Roscoe (l. c) found that 1·94 p. c. of the meteorite dissolved in ether, and from the solution he obtained crystals melting at 114° C., and in two forms: acicular, which he considered as near to könlite (Min., p. 737), and rhombic, which he identified as free sulphur.

CELESTITE, Min., p. 619; App. II., p. 10.—**Cryst.**, twins, Sicily, *Kenngott*, J. Min., 1875, 293. *Neminar* (barytocelestite), Min. Mitth., 1876, 59. Cryst. and optical exam., Jühnde, near Göttingen, *Babcock*, J. Min., 1879, 835. Perticara, *Schmidt*, J. Min., 1881, ii., 169 ref., (or Z. Kryst., vi., 99). Ville-sur-Saulx, *v. Lasaulx*, Z. Kryst., vi., 203, 1881.

Effect of heat on indices of refraction, *Arzruni*, Z. Kryst., i., 177, 1877. Pyro-electrical characters, *Hankel*, Wied. Ann., vi., 54, 1879.

Anal., occurrence in marl at Bristol, England, *Stoddart*, Min. Mag., i., 4, 1876. Clifton, England (barytocelestite), *Collie*, ib., ii., 220, 1879. Found at Bell's Mills, Blair Co., Pa. (not Frankstown, Huntington Co.). Recent formation at Bourbon d'Archambault, *de Gouvenain*, C. R., lxxx., 1299, 1875.

CENTRALLASSITE, Min., p. 796.—Composition discussed, *How*, Phil. Mag., V., i., 128, 1876.

CERARGYRITE, Min., p. 114; App. II., p. 10.—A mercurial variety of cerargyrite, from the mine "la Julia," of the Cerro de Caracoles, Desert of Atacama, is described by Domeyko

(Ann. d. Min., VII., x., 15, 1876; or Min. Chili, 3d Ed., 1879, p. 416). Amorphous, forming irregular masses. Lustre waxy, less brilliant than the pure chloride. Color on the fresh fracture reddish, yellowish, or hair-brown, becoming nearly black on exposure. Malleable and sectile, but less so than ordinary cerargyrite. Can be crushed in a mortar, yielding a bright yellowish powder. The mean of two analyses gave:

Ag	Hg	Cl	NaCl	Fe_2O_3	SiO_2 (insol.)	$CaCO_3$ and loss	
66·68	2·20	22·64	1·75	1·60	1·07	[4·06]	= 100.
91·53							

According to Moesta, the cerargyrite of Los Bordos, Copiapo, contains 1·31 p. c. of mercury.

CERBOLITE.—App. II., p. 10.

CERITE, Min., p. 418; App. II., p. 10.—Anal. by *Stolba* and *Kettner*, of cerite from Bastnäs, giving: SiO_2 18·18, Ce_2O_3 33·25, $La_2O_3 + Di_2O_3$ 34·60, FeO 3·18, CaO 1·69, H_2O 5·18 = 96·08, Ber. Böhm. Ges., p. 372, 1879.

CERUSSITE, Min., p. 700; App. II., p. 11.—Cryst., twins, *Sadebeck*, Pogg. Ann., clvi., 558, 1875. *Groth*, Min.-Samml., Strassburg, p. 133, 1878. Rodna, Transylvania, *Vrba*, Z. CERVANTITE, Min., p. 187.—Occurrence in Sevier Co., Ark., *Dunnington*, Amer. Assoc., 1877, 182.

CHABAZITE, Min., p. 434; App. II., p. 11.—*Becke* has studied minutely the optical characters of chabazite crystals from different localities, and concludes that the long recognized optical anomalies are to be explained by the assumption of a complicated twinning of triclinic individuals; this twinning, however, is according to the accepted principles (analogous to aragonite), and does not require any new hypothesis as that of Mallard. He finds, for example, that a basal section in polarized light shows a composition of six differently orientired individuals, of which the extinction directions of two neighboring portions are symmetrically arranged with reference to the line of union. A section parallel to a rhombohedral plane, under the same conditions, is divided into two parts along the shorter diagonal. For further details see the original paper (Min. Petr. Mitth., ii., 391, 1879), or the abstracts (Z. Kryst., v., 377, and J. Min., 1880, ii., 135). *Streng* (see below) also discusses the same problem, but without arriving at so definite a conclusion. *Becke* finds gmelinite related in structure to chabazite, while herschelite (q. v.) differs from both, and to the latter levynite is probably related. *Des Cloizeaux* (Bull. Soc. Min., iv., 259, 1881) has examined optically the haydenite of Baltimore, double-refraction positive.

Discussion of chemical composition with several analyses (by Burkhardt and Hammerschlag), *Streng*, Ber. Oberhess. Ges., xvi., 74, 1877 (abstr., Z. Kryst., i., 519, 1877); he shows the variation in composition (e. g. of 4·4 p. c. in SiO_2), and argues from it that this and the related species (phacolite, gmelinite, levynite) may be regarded as varying isomorphous mixtures of two end compounds, as has been assumed in the case of the triclinic feldspars.

Anal., Csódiberg, Hungary, *Koch*, ZS. G. Ges., xxviii., 304, 1876. Lausanne, in a gelatinous condition (Bischoff), *Renevier*, Bull. Soc. Vaud., II., xvi., 15, 1879. Branchville, Conn. (Penfield), *Brush* and *Dana*, Am. J. Sc., xviii., 49, 1879. Elba, *Sansoni*, Att. Soc. Tosc., iv., 316, 1879.

Recent formation at Bourbonne-les-Bains, *Daubrée*, C. R., lxxx., 606, 1875; at Oran, Algiers, ib., lxxxiv., 157, 1877.

CHALCOCITE, Min., p. 52.—Recent formation at Bourbonne-les-Bains, *Daubrée*, C. R., lxxx., 462, 1875; see also xciii., 572, 1861.

Chalcomenite, *Des Cloizeaux* and *Damour*, Bull. Soc. Min., iv., 51, 1881.

Monoclinic; in isolated crystals and crystalline crusts. $I \wedge I = 108° 20'$. $O \wedge i\text{-}i = 89° 9'$. Commonly in prismatic crystals terminated by the basal plane and 1-*i*. Optic axial plane parallel, and acute (negative) bisectrix perpendicular, to the horizontal edge $O \mid i\text{-}i$. Angle small, dispersion strong $\rho < v$; so that in the polariscope with a green glass the lemniscates have the form of circular rings traversed by a black cross, while with a blue glass they take the form of ellipses elongated normal to the plane of polarization. G. = 3·76. Color bright blue. Transparent. Analysis, Damour (Bull. Soc. Min., iv., 167, 1881):

SeO_2	CuO	H_2O
48·12	35·40	15·30 = 98·82.

Corresponding to the formula $CuSeO_3 + 2aq$ or a copper selenite, an example of a group of compounds not before met with in mineralogy. B. B. on charcoal fuses to a black slag, giving off selenium fumes, and coloring the flame deep blue. In the closed tube yields a little water and a sublimate of SeO_2 in white needles. In salt of phosphorus gives in O. F. a greenish blue glass, which becomes blood-red when reduced with the addition of metallic tin. Soluble in acids.

Occurs in minute crystals in the various selenides of silver, copper, and lead, which are found in small veins; Cerro de Cacheuta, Mendoza, Argentine Republic. Often intimately mixed with azurite, iron oxide, and lead carbonate, which have been formed by the alteration of the selenides and of the pyrites which form the gangue.

MM. Friedel and Sarasin have succeeded in forming artificially (Bull. Soc. Min., iv., 176, 225, 1881) a copper selenite having the same form and composition as chalcomenite, and another differing in crystalline form.

CHALCOMICLITE.—App. II., p. 11.

CHALCOMORPHITE.—App. II., p. 11.

Chalcophanite. *G. E. Moore*, Amer. Chemist, July, 1875.

Rhombohedral; in druses of minute tabular crystals. $R \wedge R = 114° 30'$, $R \wedge O = 103° 48'$; $\dot{c} = 3·5267$. Also in foliated aggregates; in stalactitic and plumose forms. Cleavage basal perfect. H. = 2·5. G. = 3·907. Lustre metallic, brilliant. Color bluish to iron black. Streak chocolate brown, dull. Opaque. Flexible in thin laminæ. Analyses: 1, of crystals; 2, of the stalactitic form:

	MnO_2	MnO	ZnO	Fe_2O_3	H_2O
1.	59·94	6·58	(½) 21·70	0·25	11·58 = 100·05.
2.*	(½) 61·57	4·41	20·80	....	12·66 = 99·44.

* After deduction of 1·27 p. c. limonite as impurity.

Formula $(Mn, Zn)O + 2MnO_2 + 2aq$. If half the water be made basic, the formula may be written $2(\overset{\text{ii}}{R} + \overset{\text{iv}}{R})O_3 + aq$, which is equivalent to $2[R_2]O_3 + aq$. In the closed tube gives off water and oxygen, exfoliates slowly, and changes to a golden bronze color. B. B. becomes yellowish bronze to copper red in color, and fuses slightly on the edges. With borax a manganese bead; on charcoal with soda a zinc coating.

Occurs at the calamine deposits of Sterling Hill, N. J. It is a product of the decomposition of franklinite. Named from χαλκός, *brass*, and φαίνω, *to appear*, in allusion to the change of color on ignition.

CHALCOPYRITE, Min., p. 65; App. II., p. 11.—Cryst., *v. Kokscharof*, Bull., Soc. St. Pet., xix., 562, 1875. With tetrahedrite in parallel position, *Sadebeck*, Ber. Ges. Nat. Fr. Berlin, Oct., 1878 (J. Min., 1879, 154). *Groth*, Min.-Samml., Strassburg, p. 53, 1878.

Recent formation at Bourbonne-les-Bains, *Daubrée*, C. R., lxxx., 463, 1875; do. at Bourbon d'Archambault, *de Gouvenain*, ib., p. 1297.

CHALCOPYRRHOTITE.—App. II., p. 11.

Chalcosiderite. *Maskelyne* (J. Ch. Soc., July, 1875) identifies a mineral from Cornwall with the chalcosiderite of Ullmann, and shows it to be a distinct species, and not to be united with dufrenite (see Min., p. 583). Occurs in minute triclinic crystals, generally in sheaf-like groups. Cleavage easy in one direction. H. = 4·5. G. = 3·108. Color light siskin green. Analysis, Flight (l. c.):

P_2O_5	As_2O_5	Fe_2O_3	Al_2O_3	CuO	H_2O*	U_2O_3
29·93	0·61	42·81	4·45	8·15	15·00	tr. = 100·95.

* Loss at 100° C. 0·46, at 120°–130° additional loss 0·13; remainder at a red heat.

Composition expressed by the formula $2[Fe_2] P_2O_8 + [Fe_2] H_6O_6 + CuH_2O_2 + 4aq$. Implanted on andrewsite at the West Phœnix mine, Cornwall.

Chalypite.—App. II., p. 11.

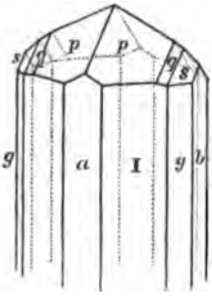
Childrenite, Min., p. 579; App. II., p. 11.—Tavistock, Cornwall, analyses by *S. L. Penfield*, Am. J. Sc. III., xix., 315, 1880:

	P_2O_5	Al_2O_3	FeO	MnO	CaO	H_2O	Quartz.
1.	30·19	21·17	26·54	4·87	1·21	15·87	0·10 = 99·95.
2.	29·98	21·44	26·20	....	....	....	....

Penfield removes the doubt as to the true composition of childrenite, the formula deduced being $R_2Al_2P_2O_{10}, 4H_2O$ or $Al_2P_2O_8 + 2RH_2O_2 + 2aq$. This requires P_2O_5 30·80, Al_2O_3 22·31, FeO 26·37, MnO 4·87, H_2O 15·65. It also follows from this that childrenite and eosphorite (see below) are essentially the same species.

Childrenite—Eosphorite. *G. J. Brush* and *E. S. Dana*, Am. J. Sci., III., xvi., 35, 1878; xviii., 47, 1879.

Orthorhombic. Axes, $\dot{c} : \bar{b} : \breve{a}$ = 0·66299 : 1·28732 : 1. Observed planes (see figure): $i\text{-}\bar{i}$ (*a*), $i\text{-}\breve{i}$ (*b*), *I*, $i\text{-}\breve{2}$ (*g*), 1 (*p*), $\frac{3}{2}\text{-}\breve{\frac{3}{2}}$ (*q*), 2–2 (*s*). $I \wedge I$ = 104° 19′, $p \wedge p$ (front) = 133° 32′, $p \wedge p$ (side) = 118° 58′, $a \wedge p$ = 120° 31. In prismatic crystals vertically striated. Also more generally massive, cleavable to closely compact. Cleavage: macrodiagonal nearly perfect.



H. = 5. G. = 3·11–3·145. Lustre vitreous to sub-resinous, of massive mineral often greasy. Color rose-pink, yellowish to colorless, also of compact forms grayish, bluish, yellowish white, and white. Streak white. Transparent to translucent. Fracture uneven to subconchoidal. Optic axial plane macrodiagonal; acute bisectrix negative, normal to brachypinacoid. Axial angle in air 54° 30′ red, 60° 30′ blue. Axial colors yellowish ($\parallel \bar{b}$), deep pink ($\parallel \breve{a}$), faint pink to nearly colorless ($\parallel \dot{c}$).

Composition: $R_2Al_2P_2O_{10}, 4H_2O$ or $Al_2P_2O_8 + 2RH_2O_2 + 2aq$. If R = Mn : Fe = 10 : 3, percentage composition: P_2O_5 30·93, Al_2O_3 22·35, FeO 7·24, MnO 23·80, H_2O 15·68 = 100. Analyses: 1, S. L. Penfield (Am. J. Sc., xvi., 40), pure crystals, G. = 3·134; 2, H. L. Wells (xvi., 41), white compact mineral, containing 14·41 p. c. impurities, mostly quartz, here deducted; 3, H. L. Wells (xviii., 48), pink massive mineral, G. = 3·11.

	P_2O_5	Al_2O_3	FeO	MnO	CaO	Na_2O	H_2O	
1. (½)	31·05	22·19	7·40	23·51	0·54	0·33	15·60	= 100·62, Penfield.
2.	31·43	21·83	6·84	22·43	3·01	....	15·07	= 100·61, Wells.
3.	31·39	21·34	6·62	22·92	1·48	....	15·28,	insol. 1·46 = 100·49, Wells.

In the closed tube decrepitates, whitens, gives off abundance of neutral water, and the residue turns first black, then gray, and finally liver brown with a metallic lustre, and becomes magnetic. B. B. in the forceps cracks open, sprouts and whitens, colors the flame pale green, and fuses at about 4 to a black magnetic mass. Reacts for iron and manganese with the fluxes. Soluble in acids.

Occurs at Branchville, Fairfield Co., Conn., in a vein of pegmatite associated with rhodochrosite and the manganesian phosphates, triploidite, dickinsonite, lithiophilite. Also as imbedded nodules (anal. 3, above), in a massive green chloritic mineral. The massive mineral (anal. 2, above, G. = 2·92–3·08) often impure from the presence of quartz, dickinsonite, and apatite. Named from *ἑωσφόρος* (synonym of *φωσφόρος*) which means *dawn-bearing*, in allusion to the characteristic pink color.

[Since the hitherto uncertain composition of childrenite (q. v.) has been settled by Penfield, it appears that eosphorite and childrenite, having similar form and composition, are essentially the same mineral, only differing in that the first contains mostly manganese and the second mostly iron.]

Chlorallumimite. *Scacchi*, Att. Accad. Napoli, vi. (read Dec. 13, 1873). Aluminum chloride ($Al_2Cl_6 + xH_2O$), produced with molisite and chloromagnesite, at Vesuvius, at the eruption of April, 1872.

CHLORASTROLITE.—See *Prehnite*, p. 96.

CHLORITE. Pseudomorph after garnet, Lake Superior, *Pumpelly*, Am. J. Sc., III., x., 17, 1875.

Chemical monograph of the "Chlorite Group," *Heddle*, Trans. Roy. Soc. Ed., xxix., 55 et seq., 1879.

CHLORITOID, Min., p. 504.—See *Clintonite*, p. 28.

CHLOROCALCITE, App. II., p. 11.—*Scacchi*, Att. Accad. Napoli, vi., 1873.

Calcium chloride, from Guy's Cliff, Warwickshire, *Spiller*, J. Ch. Soc., p. 154, Feb., 1876. Calcium chloride, more or less mixed with clay, has been identified in the Province of Tarapaca, of Chincha, and elsewhere in Peru, by *Raimondi* (Min. Pérou, p. 267, 1878); it was called HYDROPHILITE by Adam.

Chloromagnesite. *Scacchi*, Att. Accad. Napoli, vi., 1873. Magnesium chloride ($MgCl_2 + x$aq), formed at Vesuvius at the eruption of April, 1872.

A mineral, apparently identical with that of Scacchi, has been called BISCHOFITE by *Ochsenius* and *Pfeiffer*, Arch. Pharm., III., xi., 296, 1877 (Bull. Soc. Min., i., 128, 1878, and Jahresb. Ch., 1877, 1284, 1285). Crystalline-granular and foliated, sometimes fibrous. H. = 1–2. G. = 1·65. Colorless (pure) to white. Lustre vitreous to dull. Mean of two analyses by König gave: Mg 11·86, Cl 35·04, H_2O 53·10 = 100; this corresponds to $MgCl_2$ + 6aq, requiring Mg 11·83, Cl 34·95, H_2O 53·22. Soluble in 0·6 parts of cold water. Occurs in layers 2–3 cm. thick in halite, with kieserite and carnallite, fibres transverse to the layers; Leopoldshall, Prussia. The assumption of water is said to commence as soon as the layer is exposed to the air. The artificial salt is monoclinic.

CHLOROPAL, Min., p. 461.—Anal., Mugrau, Bohemia, *Schrauf*, J. Min., 1877, 255. Mudgee, New South Wales, *Liversidge*, Proc. Roy. Soc. N. S. W., Nov. 3, 1880. A related mineral from Sweden, *Weibull*, Geol. För. Förh., v., 627, 1881.

Composition of related minerals discussed, *Collins*, Min. Mag., i., 67, 1877.

CHLOROPHÆITE, Min., p. 510.—Anal., from the Scuir More ridge, in Rum, Scotland, *Heddle* (Trans. Soc. Edinb., xxix., 84, 1879): SiO_2 36·00, Fe_2O_3 22·80, FeO 2·46, MnO 0·50, CaO 2·52, MgO 9·50, alkalies tr., H_2O 26·46 = 100·25 (H_2O at 100° 19·28).

Chlorothionite, *Scacchi*, Att. Accad. Napoli, vi., 1873 (Contrib. Min., ii., p. 59).

Occurs in thin crystalline mammillary crusts of a bright blue color. An analysis gave: SO_4 32·99, Cl 20·04, Cu 19·56, K 26·29, loss 1·12 = 100. Crystals obtained by recrystallization from a solution, and thus purer than the original material, gave essentially the same result. The composition is expressed by the formula $K_2SO_4 + CuCl_2$, which requires: SO_4 31·12, Cl 22·98, Cu 20·55, K 25·35 = 100. From Vesuvius, as a result of the eruption of April, 1872. The name records the presence of chlorine and sulphur (θεῖον). [Is not this a mixture of two salts ?].

Chlorotile. *Frenzel*, Min. Mitth., 1875, 42; J. Min., 1875, 517.

In minute capillary crystals of prismatic habit (orthorhombic), also fibrous and massive; soft. Color in the mass pale green to emerald green, microscopic crystals colorless. Transparent. Composition asserted to be $Cu_3As_2O_8 + 6aq$; an approximate analysis gave: As_2O_5 41, CuO 41, H_2O 18 = 100. Occurs with aragonite and wapplerite, at Schneeberg. and with quartz and scheelite at Zinnwald. [A more complete description is to be desired.]

CHONDRODITE, Min., p. 363; App. II., p. 12.—**Cryst.**, Brewster, N. Y., monograph by *E. S. Dana*, proving the presence of crystals corresponding to each of the so-called "types" of the Vesuvian humite; also giving measurements and many occurring planes. Further, it is shown, that the optical characters of the crystals of the more common "second type" prove them to be, in fact, *monoclinic:* the axes lie in the plane of symmetry, axial plane inclined 25° 48′ to the basal plane, $2H_{a.\rho} = 88° 48'$ ($n = 1{\cdot}466$), Conn. Acad., iii., 67–96, 1875 (abstr. in Am. J. Sc., III., x., 89). It has also been proved by the same author, that the crystals of the "third type" belong to the monoclinic system (Am. J. Sc., III., xi., 139, 1876). The measured angles alone, however, would not imply any variation from the orthorhombic type, although it has long been observed that the hemihedral development of the planes was in accordance with monoclinic symmetry.

The corresponding Vesuvian species, HUMITE, has been studied by *Des Cloizeaux* (Phil. Mag. III., ii., 286, 1876, and iii., 357, 1877; or see J. Min., 1876, 641; 1877, 500) and by *Klein* (J. Min., 1876, 633). Des Cloizeaux finds the three types of humite to be optically distinct, and proposes to retain for the "first type," which he shows to be orthorhombic, the name HUMITE; for the "second type," which he finds to be monoclinic, he retains the name CHONDRODITE, and to the "third type," also monoclinic, he gives the name CLINOHUMITE (the observations on the second and third types confirm those of E. S. Dana on Brewster crystals). Klein (l. c.) obtained for third type crystals of humite (*clinohumite*) results agreeing with those of Des Cloizeaux.

Sjögren describes crystals from the Ladu mine, Wermland, Sweden, which are holohedral orthorhombic, and near in angle to "Type I." of the Vesuvian mineral, also others from Kafveltorp, Westmanland, which are monoclinic, and similar (see above) to common chondrodite, Œfv. Ak. Stockh., xxxviii., 5, p. 29, 1881. An exhaustive monograph of the Kafveltorp chondrodite is given by the same author in vol. xvii. of the Lund. Univ. Årsskrift (abstr. in Geol. För. Förh., v., 655, 1881).

Analyses and discussion of composition: Brewster, N. Y., *Hawes*, Am. J. Sc., III., x., 96, 1875; Kafveltorp, Sweden, *Widman*, Geol. För. Förh., iii., 118, 1876; *Websky*, Ber. Ak. Berlin, 1876, 201; Pargas, Finland, *Berwerth*, Min. Mitth., 1877, 272.

CHROMITE, Min., p. 153; App. II., p. 12.—In thin sections not opaque, but transmits a yellowish-red color, according to *Thoulet*, Bull. Soc. Min., ii., 34, 1879. See also *Fischer*, Mikr. Stud., 1870, and Z. Kryst., iv., 363.

Anal., platinum washings, Wisimo Schaitansk, Ural, *Waller*, Œfv. Ak. Stockh., xxxiii., No. 10, p. 23, 1876.

Occurrence in meteorites, *J. Lawrence Smith*, Am. J. Sc., III., xxi., 461, 1881.

Chromowulfenite.—See *Wulfenite*, p. 182.

CHROMPICOTITE.—App. I., p. 3.

CHRYSOBERYL, Min., p. 155; App. II., p. 12.—**Specific gravity determinations**, *Church*, Geol. Mag., II., ii, 321, 1875.

CHRYSOCOLLA, Min., p. 402.—An aluminous variety of chrysocolla is called PILARITE by *Kramberger* (Z. Kryst., v., 260, 1880). Like chrysocolla in appearance. Apparently homogeneous under the microscope. H. = 3. G. = 2·62. Lustre dull. Color light greenish blue. Analysis (½): SiO_2 38 6, Al_2O_3 16·9, CuO 19·0, CaO 2·5, ign. 21·7 = 98·7. Locality, Chili. Named after Prof. Pilar in Agram.

J. R. Santos (Chem. News, xxxvi., 167, 1876) has analyzed an aluminous chrysocolla from Utah: SiO_2 37·19, Al_2O_3 10·78, CuO 26·03, H_2O 25·76 = 99·76. König describes a substance from Bergen's Ranch, 25 m. from Denver, Col., forming a thin, slightly bluish crust on limonite; it contains 33·85 p. c. Al_2O_3, 5·40 CuO, and corresponds to allophane and chrysocolla in the ratio of 5 : 1, probably to be regarded as a mixture, Proc. Ac. Nat. Sc. Philad., 1877, 294. See also *Semmons*, Min. Mag., ii., 197, 1879.

Other analyses, Lower California, *Hutchings*, Chem. News, xxxvi., 18, 1877; also xxxiv., 141, 1876; Cerro Blanco, Chili, *Pellegrini*, Z. Kryst., iv., 408; Wheco, New South Wales, *Liversidge*, Proc. Roy. Soc. N. S. W., Nov. 3, 1880.

CHRYSOLITE, Min., p. 256; App. II., p. 12.—Vesuvius (hyalosiderite), *Scacchi*, Att. Acc. Nap., vi., 1873 (Contr. Min., II., 66); with humite (clinohumite) crystals in parallel position, *Scacchi*, J. Min., 1876, 637. Determinations of specific gravity, *Church*, Geol. Mag., II., ii., 321, 1875.

Anal., Skurruvuselv, Norway, *Hjortdahl* (Z. Kryst., ii., 305). Zermatt, with 6 p. c. TiO_2 (titanolivine, Groth), *Damour*, Bull. Soc. Min., ii., 15, 1879. In meteoric iron of Bragiu, Retschinsk, *Inostranzef*, Min. Russl., vi., 216; Ste. Anne, Ottawa River, Canada, *Harrington*, Geol. Canada, 1878.

A variety is called NEOCHRYSOLITE, by *Scacchi* (Rend. Accad. Napoli, Oct. 14, 1876). In small, black, crystalline plates, crystallographically identical with chrysolite. Peculiar in containing a considerable amount of manganese (compare hortonolite). Found in the cavities of the lava of 1631, at the Cupa di Sabataniello, Vesuvius.

CHRYSTOPHITE.—See *Sphalerite*, p. 111.

CIMOLITE, Min., p. 457.—**Anal.**, Richmond, N. S. W., *Liversidge*, Proc. Roy. Soc. New South Wales, Dec. 6, 1876.

CINNABAR, Min., p. 55; App. II., p. 12.—**Cryst.**, *v. Kokscharof*, Min. Russl., vi., 257, 1875. With metacinnabarite, Reddington mine, Cal., *Bertrand*, Z. Kryst., ii., 199, 1877. Tuscany, *d'Achiardi*, Att. Soc. Tosc., iii., 282, 1877.

Anal., Oregon, *Dabney*, Chem. News, xxxiv., 180, 1876.

Occurrence in California, etc., *Blake*, Bull. Soc. Min., i., 81, 1878; Rolland, ib., i., 98. Genesis, etc., *Christy*, Am. J. Sc., III., xvii., 453, 1879; Mernyik, Hungary, *Krenner*, Z. Kryst., ii., 304.

CLARITE, App. II., p. 12.—*Sandberger*, J. Min., 1875, 882.

Monoclinic (?). Crystals in tufted groups, on account of alteration not to be measured; planes identified *O*, *i-i*, *I*, *m*. Cleavage *i-i* perfect, *i-i* less so. H. = 3·5. G. = 4·46. Color dark lead gray. Streak black. Analysis, Petersen:

S	As	Sb	Cu	Fe	Zn
32·92	17·74	1·09	46·29	0·83	tr = 98·87.

Formula that of enargite, viz.: $Cu_3AsS_4 = 3Cu_2S + As_2S_5$.

B. B. fuses easily; in the closed tube decrepitates violently, and gives a reddish yellow sublimate of the sulphide of arsenic (and antimony), with also one of sulphur; in the open tube gives both As_2O_3 and Sb_2O_3. Soluble in nitric acid, with the separation of a white precipitate; not attacked by boiling in a solution of caustic potash. Occurs on barite from the Clara mine, near Schapbach, Baden. Sometimes altered to chalcopyrite and covellite. [Clarite and luzonite have both the composition of enargite; the former differs from it in color, and apparently in form; the latter in color and absence of cleavage, form unknown. All three have essentially the same specific gravity, which is not ordinarily the case with well established trimorphous groups—a further examination seems to be required to prove that they are in fact distinct.]

CLAUSTHALITE.—Min., p. 497; App. II., 12.

Cleveite. *Nordenskiöld*, Geol. För. Förh., iv., 28, 1878.

Isometric; in cubes with octahedron and dodecahedron; crystals rare, also in irregular grains. H. = 5·5. G. = 7·49. Lustre dull. Color iron black. Streak blackish brown.

Opaque. Analysis, G. Lindström (l. c.), after deducting 2·34 p. c. insol., and 0·36 CaO, 0·14 MgO:

U_2O_3	Y_2O_3	Er_2O_3	Ce_2O_3	Fe_2O_3	ThO_2	PbO	UO	H_2O
42·04	6·87	3·47	2·33	1·05	4·76	11·31	23·89	4·28 = 100.

The suggestion is made that the formula may be $(RO)(R_2O_3)H_2O$, and the mineral a member of the spinel group, altered through the assumption of water, but this seems very doubtful. In the closed tube gives off water. B. B. infusible. With salt of phosphorus a deep green bead, becoming yellow in O. F. after long blowing. Easily soluble in hydrochloric acid with the separation of lead chloride. With soda on charcoal, a lead globule and a coating of lead oxide. Occurs in a dirty brown feldspar at Garta, near Arendal, Norway. Associated with orthite, fergusonite, thorite, etc. Named after Prof. Cleve.

At the same locality is found a mineral which is probably a final decomposition product of cleveite. It is called YTTROGUMMITE. It has the appearance of orangite. Lustre brilliant. Color black to yellow. Translucent; fracture conchoidal. Optically anisotrope. H. = 5. Hydrous, contains yttrium and uranium oxides. Between the black opaque cleveite and the translucent honey yellow yttrogummite, occur many intermediate products. [Cleveite is closely related to uraninite, as is yttrogummite to ordinary gummite.]

Clinocrocite (*Sandberger*), *Singer*, Inaug. Diss., Würzburg, 1879, p. 9. A mineral of a deep saffron yellow, occurring in microscopic crystals (·02 mm. broad), which are probably monoclinic, with the planes *I*, *O*, 1-*i*. According to a qualitative examination, a hydrous sulphate of alumina, iron sesquioxide, soda, and potash (lime in traces). From the Bauersberg, near Bischofsheim, formed by the decomposition of pyrite in basalt tufa. Related to the more clearly defined mineral, *clinophæite* (q. v.). [Needs further examination.]

Clinohumite.—See *Chondrodite*, p. 26.

Clinophæite (*Sandberger*), *Singer*, Inaug. Diss., Würzburg, 1879, p. 16. In microscopic crystals (·02 mm. broad), probably monoclinic, with planes *O*, *I*, 1-*i*, prismatic angle 85°. H. = ? G. = 2·979. Color blackish green. Streak light grayish green. Lustre vitreous. Translucent to opaque. Taste astringent. An analysis gave (after deducting 7·88 p. c. hygroscopic water):

SO_3	Fe_2O_3	Al_2O_3	FeO	NiO(CoO)	MgO	CaO	Na_2O	K_2O	H_2O
37·01	9·48	4·04	6·06	0·76	1·88	0·77	6·35	21·79	14·72 = 102·86.

The formula deduced is $5R_2SO_4 + [R_2]H_6O_6 + 5aq$. Difficultly soluble in water; on boiling, iron sesquioxide separates from the aqueous solution. B. B. fuses with intumescence, leaving finally a black magnetic residue. Occurs with other sulphates at the Bauersberg, near Bischofsheim, as a result of the decomposition of pyrite.

CLINTONITE, Min., p. 508.—The "clintonite group" of minerals have been investigated by *Tschermak* and *Sipöcz* (Ber. Ak. Wien, lxxviii., Nov., 1878; or Z. Kryst., iii., 496). In this group of "brittle micas" (*Sprödglimmer*) the authors include seybertite (clintonite), brandisite, xanthophyllite, also chloritoid, masonite, ottrelite, sismondine, and sapphirine. All of these species belong to the monoclinic system, and in form and physical character they are closely related to the micas, more especially to margarite (see original memoir and p. 77).

Chemically, it is assumed that the first three of these minerals are isomorphous mixtures of $H_4Ca_2Mg_8Si_6O_{24}$ and $H_2CaMgAl_6O_{12}$: in *seybertite* in the ratio of 4 : 5, in *brandisite* of 8 : 4, in *xanthophyllite* of 5 : 8. As the two compounds assumed are not known to have an independent existence, the results reached are hypothetical. In order to bring out the relation which is supposed to exist between the micas, margarite, and seybertite, the following scheme is given, representing the compounds which are assumed to enter into their composition:

Mica.	Margarite.	Seybertite.
$\left.\begin{matrix}H_6Al_6Si_6O_{24}\\Mg_{12}Si_6O_{24}\end{matrix}\right\}$	$\left.\begin{matrix}H_6Al_6Si_6O_{24}\\Ca_3Al_6O_{12}\end{matrix}\right\}$	$\left.\begin{matrix}H_4Ca_2Mg_8Si_6O_{24}\\H_2CaMgAl_6O_{12}\end{matrix}\right\}$

Chloritoid (chloritspath) is also monoclinic, and related in form to meroxene, as well as to the above species; composition expressed by the formula $H_2Fe_2Si_2O_7 + H_2Al_2O_7$.

Ottrelite and *masonite* are regarded as very near to chloritoid, the variation in chemical composition being believed to be due to foreign inclosures.

Sismondine is similar to chloritoid, and the formula corresponding to the analysis below is $H_{14}Fe_7Al_{12}Si_6O_{44}$, with, however, the Fe in part replaced by Mg. For sapphirine the formula $Mg_2Si_2O_6 + Mg_2Al_6O_{11}$ is given.

Analyses: 1, 2, 3, by L. Sipöcz—1, seybertite from Amity, G. = 3·102; 2, brandisite from Monzoni, G. = 3·090; 3, chloritoid from Pregratten, G. = 3·538; 4, by W. Suida, sismondine from St. Marcel, G. = 3·42.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	H_2O	F	
1. *Seybertite*	19·19	39·73	0·61	1·88	21·09	13·11	4·85	1·26	= 101·72.
2. *Brandisite*	18·75	39·10	3·24	1·62	20·46	12·14	5·35	....	= 100·66.
3. *Chloritoid*	24·90	40·99	0·55	24·28	3·33	....	7·82	....	= 101·87.
4. *Sismondine*	26·03	42·33	4·09	14·32	7·30	0·35	6·56	alk. *tr.*	= 100·98.

On a variety of xanthophyllite called WALUEWITE, see p. 132: on a variety of ottrelite called VENASQUITE, see p. 87.

COBALTITE, Min., p. 71; App. II., p. 13.—**Cryst.**, Tunaberg and Skutterud, *Groth*, Min.-Samml., Strassburg, p. 41, 1878.

Anal., Khetri mines, Rajputana, India, *F. R. Mallet*, Rec. Geol. Surv. India, xiv., pt. 2, 190, 1880.

CŒRULEOLACTITE.—App. I., p. 3; II., p. 13.

Coloradoite, *F. A. Genth*, Amer. Phil. Soc., xvii., 115, 1877 (or Z. Kryst., ii., 4).

Massive; granular, sometimes imperfectly columnar (due to admixed sylvanite ?). H. = 3. G. = 8·627. Lustre metallic. Color iron-black inclining to gray. Fracture uneven to subconchoidal. Composition HgTe = tellurium 39·02, mercury 60·98 = 100. Analyses; 1, 2, 3, 4, 5, Keystone mine; 6, 7, Smuggler mine.

	Quartz and gold deducted.	Te	Hg	Al_2O_3, Fe_2O_3	V_2O_3	MgO	CaO	
1.	[28·50]	43·81	56·33	tr.	tr.	tr.	tr.	= 100·14.
2.	[46·83]	42·95	52·28	2·44	0·70	0·11	0·84	= 99·32.
3.	[25·18]	44·25	51·48	undet.				
4.	[8·46]	46·74	49·80	undet.				
5.	[20·72]	50·05	45·63	undet.				
	Quartz deducted.							
6.	[2·90]	36·24	55·80	Au 3·46, Ag 2·42, Fe 1·35, Cu, Zn tr. = 99·27.				
7.	[3·05]	34·49	48·74	Au 7·67, Ag 7·18, Cu 0·16, Fe 0·92, Zn 0·50 = 99·66.				

The impurities present in 1 to 5 are, besides gold and quartz, native tellurium in varying quantities; in 6 and 7 also sylvanite. In the tube slightly decrepitates, fuses, and yields metallic mercury as a sublimate, also tellurium trioxide in drops, and next to the assay metallic tellurium. Soluble in nitric acid.

Occurs very sparingly at the Keystone, Mountain Lion, and Smuggler mines, in Colorado. [Belongs in the same group with cinnabar (or metacinnabarite) HgS, and tiemannite HgSe.]

COLUMBITE, Min., p. 515; App. II., p. 13.—**Cryst.**, Riesengebirge, *Scharizer*, Verh. G. Reichs., 1879, 243.

Analyses, Yancey Co., N. C.; Pike's Peak, Col., *J. L. Smith*, Am. J. Sc., III., xiii., 359, 1877. Isergebirge, *Janovsky*, Ber. Ak. Wien, lxxx., 34, 1879. Middletown, Ct., *E. J. Hallock*, Am. J. Sc., xxi., 412, 1881.

The following analyses are quoted here as being of especial interest: 1, Standish, Me., *O. D. Allen* (priv. contrib.); 2, Northfield, Mass., *W. J. Comstock*, Am. J. Sc., III., xix., 181, 1880; 3, Branchville, Conn., *Comstock*, ib.

		Cb_2O_5	Ta_2O_5	SnO_2, WO_3	MnO	FeO	CaO	
1. Standish,	G. = 5·65	68·99	9·22	1·61	3·65	16·80	...	= 100·27.
2. Northfield,	G. = 6·84(?)	26·81	56·90	...	5·88	10·05	...	= 99·64.
3. Branchville,	G. = 6·59	30·16	52·29	...	15·58	0·43	0·37	= 98·83.

The Standish crystals are small, but highly modified, and of brilliant lustre (see Z. Kryst., i., 380). The Northfield mineral had the form and habit of ordinary columbite, though it is essentially a tantalite. This was also true of the Branchville mineral (*Brush* and *Dana*, Am. J. Sc., III., xvi., 34, 1878), which, moreover, was in thin tabular crystals, slightly *translucent;* it is also remarkable as containing only MnO, and also in the fact that the ratio of $Cb_2O_5 : Ta_2O_5 = 1:1$ nearly, that is, the formula is $MnCb_2O_6 + MnTa_2O_6$. See also *Tantalite*, p. 118.

Shepard's HERMANNOLITE (Am. J. Sc., II., l., 90, 1870; III., xi., 140, *Hermann*, J. Pr. Ch., II., xiii., 386, 1876, or Bull. Soc. Mosc., xlix., 179, 1875; *Delafontaine*, Am. J. Sc., III. xiii., 390, 1877, and Bibl. Univ. Gen., II., lix., 184, 1877) is a mineral from Haddam, Conn. related to (or identical with) columbite. Hermann (l. c.) finds in it "hypotantalic acid 7·03, hypoilmenic acid 14·92, niobous acid 56·15, iron protoxide, 12·56, manganese protoxide 9·34 = 100." This result is, to say the least, problematical, as no one but the analyst himself has any confidence in the existence of the chemical compounds named. Delafontaine (l. c.) found a large proportion of Cb_2O_5, about 16 p. c. Ta_2O_5, and possibly a little TiO_2. He states further, that the low specific gravity supposed to be a specific character of this substance is explained by its containing less Ta_2O_5 (Brainerd's columbite contains 37 p. c.), and by the admixture of some foreign material. [As far as investigation has gone, hermannolite is not distinct from columbite.]

CONNELLITE, Min., p. 627.—Optically uniaxial, positive, *Bertrand*, Bull. Soc. Min., iv., 88, 1881.

COPIAPITE, Min., p. 655; App. II., p. 13.—Optical characters, *Bertrand*, Bull. Soc. Min., iv., 11; *Des Cloizeaux*, ib., 41, 1881.

COPPER, Min., p. 14; App. II., p. 13.—Cryst., *v. Kokscharof*, Min. Russl., vi., 209, 1874. Altai, *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xii., 281. Mine Friedrichssegen, Nassau, *Seligmann*, Verh. Nat. Ver. Rhein., xxxiii., 261, 1876. Lake Superior, *vom Rath*, Z. Kryst., ii., 169, 1878; *Fletcher*, Phil. Mag., V., ix., 180, 1880.

Pseudomorphs after aragonite, from Coro-Coro, Bolivia, described fully, *Domeyko*, 6th App. Min. Chili, p. 6, 1878.

COQUIMBITE, Min., p. 650; App. II., p. 13.—Copiapo, Coquimbo, Chili, revision of angles, c (vert) = 1·5645, optical examination, *Arzruni*, with analyses by *Bamberger*, confirming Rose's results, Z. Kryst., iii., 516, 1879.

CORDIERITE.—See *Iolite*, p. 63.

CORKITE.—App. II., p. 13; see also *Beudantite*, p. 15.

CORNWALLITE.—Min., p. 569; App. II., p. 13.

Coronguite, *Raimondi*, Minéraux du Pérou, 1878, pp. 88, 91.

Amorphous, earthy, pulverulent, sometimes slightly lamellar. H. = 2·5–3. G. = 5·05. Color, exterior, grayish yellow; interior, blackish, with lustre slightly resinous. Intimately mixed with small quantities of sulphur, antimony, silver, and lead. An analysis, after the deduction of impurities, gave: Sb_2O_5 58·97, PbO 21·48, Ag_2O 7·82, FeO 0·52, H_2O 11·21 = 100; accordingly, an antimonate of lead and silver. Found at the mines of Mogollon, Huancavelica, and Empalme, in the district of Corongo, province Pallasca, and at Pasacancha, province of Pomabamba, Peru. [Of doubtful homogeneity.]

CORUNDOPHILITE, Min., p. 504; App. II., p. 13.—A mineral, apparently identical with corundophilite, is called AMESITE, by Shepard. Occurs with diaspore at Chester, Mass. Examined by Pisani (C. R., lxxxiii., 166, 1876). In hexagonal plates, foliated, resembling the green talc from the Tyrol. Uniaxial figure (positive), seen through cleavage fragment. H. = 2·5–3. G. = 2·71. Color apple green. Lustre pearly on cleavage face. Analysis:

SiO_2	Al_2O_3	Fe	MgO	H_2O	
21·40	32·30	15·80	19·90	10·90	= 100·30.

Q. Ratio for Si : $[Al_2]$: R : H = 9 : 12 : 10 : 8. B. B. nearly infusible.

CORUNDUM, Min., p. 137; App. II., p. 13.—Cryst., Ceylon, *v. Kokscharof*, Min. Russl., vi., 228, 1874. Taschkent, etc., *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xiii., 426, 440; xiv., 227 (Z. Kryst., ii., 504, 505; iii., 438; iv., 642).

Specific gravity determinations, *Church*, Geol. Mag., II., ii., 321, 1875.

Made artificially (rubies, sapphires), *Frémy* and *Feil*, C. R., lxxxv., 1029, 1877; *Meunier*, ib., xc., 701, 1880.

Occurrence of emery in Westchester Co., N. Y., *Kimball*, Am. Chem., iv., 9, 321, 1874; *J. D. Dana*, Am. J. Sc., III., xx., 200, 1880.

Mallard (Ann. Min., VII., x. 150, 1876), describes crystals, in which a basal section consisted of six sectors; he assumes that the apparently rhombohedral crystals are really composed of three orthorhombic individuals. *Bertrand* (Bull. Soc. Min., i., 95, 1878), describes crystals from Siam (ruby) which are distinctly biaxial, with a widely varying axial angle from nearly 0° up to 58°. *Tschermak* (Min. Petr. Mitth., i., 362, 1878), mentions crystals from Ceylon having a monoclinic symmetry in the distribution of the planes, and also optically biaxial. He concludes that many crystals are built up of monoclinic particles, occasionally so grouped as to give uniaxial effects in polarized light.

COSALITE, Min., p. 797; App. II., p. 13.—A mineral, apparently identical with cosalite, is called BJELKITE by *Sjögren* (Geol. För. Förh., iv., 106, 1878; ett nytt vismuthsvafladt svafelbly, *Lundström*, ib., ii., 178, 1874). Its characters are as follows: Massive, fibrous, radiated. H. = 2·5–3. G. = 6·39–6·75. Lustre metallic. Color steel gray. Streak grayish black. Composition $Pb_2Bi_2S_5 = 2PbS + Bi_2S_3$. Analyses: 1, Lundström (l. c.); 2, 3, Sjögren (l. c.).

	S	Bi	Pb	Fe
1.	17·83	39·40	37·64	5·18 = 100, Lundström.
2.	15·98	41·55	40·10	0·67, insol. 2·19 = 100·49, Sjögren.
3.	16·48	41·86	39·19	1·32 = 98·85, Sjögren.

The material used in (1) was probably more or less impure through the presence of a little pyrrhotite. B. B. fuses easily, giving reactions for lead, bismuth, and sulphur; slowly attacked by HCl, dissolved in fuming nitric acid, with the separation of lead sulphate From the Bjelke mine, in Nordmark, Wermland, Sweden.

Cossyrite, *H. Foerstner*, Z. Kryst., v., 348, 1881.

Triclinic, with $\alpha = 90° 6'$, $\beta = 102° 12'$, and $\gamma = 89° 54'$, $I \wedge I' = 114° 5'$. Form near that of amphibole, but differing in the prismatic zone. Cleavage I and I' distinct. Twins with the brachypinacoid as twinning plane. Crystals minute, 1·5 mm. long, and 0·5–0·6 mm. broad. G. = 3·74–3·75. Color black. Analysis:

SiO_2	Fe_2O_3	Al_2O_3	FeO	MnO	CuO	MgO	CaO	Na_2O	K_2O
43·55	7·97	4·96	32·87	1·98	0·39	0·86	2·01	5·29	0·33 = 100·21.

Approaches in composition some ferruginous amphiboles. B. B. fuses easily to a brownish black glass. Partially decomposed by acids. Found imbedded in the liparite lavas of the island Pantellaria, whose ancient name was Cossyra. The crystals examined were weathered out of the ground mass.

Cotterite.—See *Quartz*, p. 101.

COTUNNITE, Min., p. 117; App. II., p. 13.—In semi-crystalline masses of a whitish color, with a tinge of yellow or green, with other lead minerals, Montagne de Challacallo, *Raimondi*, Min. Pérou, p. 172, 1878.

COVELLITE, Min., p. 83.—Anal., New Annan, Nova Scotia, *Louis*, Trans. N. S. Inst., iv., 424, 1878.

CROCIDOLITE, Min., p. 243; App. II., p. 13.—An analysis by Dölter (Z. Kryst., iv., 40, 1879), afforded: SiO_2 52·11, Al_2O_3 1·01, Fe_2O_3 20·62, FeO 16·75, MgO 1·77, Na_2O [6·16], H_2O 1·58 = 100; locality South Africa. This confirms the ordinary belief as to its close relation to arfvedsonite (q. v., p. 9).
See also *Abriachanite*, p. 1.

CROCOITE, Min., p. 628.—Cryst., *v. Kokscharof*, Min. Russl., vii., 97, 1877.
Occurrence in Arizona, *Silliman*, Am. J. Sc., III., xxii., 208, 1881.

CRONSTEDTITE, Min., p. 503; App. II., p. 13.—Cryst., Przibram, etc., *v. Zepharovic* Ber. Ak. Wien, lxxi., 276, 1875. In parallel position with pyrite crystals, *id.*, Lotos, 18
Anal., Przibram, *Janovsky*, J. pr. Chem., II., xi., 378, 1875. Cornwall, *Field*, Ph. Mag., V., v., 52, 1878.

CRYOCONITE, App. II., p. 13.—Original material examined by *v. Lasaulx* proved to consist principally of quartz and mica, with also feldspar, hornblende, magnetite, garnet, and probably epidote and cyanite; metallic iron was not identified. The composition is near that of a gneiss, and *v. Lasaulx* concludes that the supposed cosmical dust of *Nordensk* is in fact terrestrial, and probably came from the gneiss region of the coast of Greenland. Min. Petr. Mitth., iii., 521, 1881.

CRYOLITE, Min., p. 126; App. II., p. 14.—Greenland, monoclinic instead of triclinic, according to *Krenner*, J. Min., 1877, 504.
Artificial alteration products, *Nöllner*, ZS. G. Ges., xxxiii., 189, 1881.

Cryptohalite. A fluo-silicate of ammonium (NH_4F, SiF_2), whose probable existe with sal ammoniac in a Vesuvian fumarole is suggested by *Scacchi*, Att. Accad. Napo vi.; Contr. Min., ii., 37, 1874.

CRYPTOLITE, Min., p. 529.—In apatite from Arendal, *Fischer*, Z. Kryst., iv., 374, 188
See also *Rhabdophane*.

CRYSTALLITES.—App. II., p. 14.

CUBANITE.—Min., p. 65; App. II., p. 14.

CULSAGEEITE.—App. II., p. 14 (30)

CUPRITE.—Min., p. 133; App. II., p. 14.

CUPROAPATITE.—App. II., p. 14.

Cuprocalcite. *Raimondi*, Domeyko, 5th Append., Min. Chili, 1876; Min. Pérou, p. 135, 1878. In small masses and in bands intimately mixed with a ferruginous calcite. H. = 3. G. = 3·90. Color bright vermilion red. Analysis gave: Cu_2O 50·45, CaO 20·16, CO_2 24·00, H_2O 3·20, Fe_2O_3 0·60, Al_2O_3 0·20, MgO 0·97, SiO_2 0·30 = 9 ·88. Formula deduced $(Cu_2O)_2CO_2 + 2CaCO_3 + H_2O$. Soluble in hydrochloric acid with effervescence; the solution, formed out of contact with the air, has a strong deoxidizing power, precipitating gold from solutions of gold salts. From the mines of Canza, near the city of Ica, Peru. [According to the results of Damour this is only an intimate mixture of calcium carbonate and copper oxide (Cu_2O), Bull. Soc. Min., i., 130, 1878.]

Cupromagnesite.—App. II., p. 14.

Cuproscheelite.—Min., p. 606; App. II., p. 14.

Cuprotungstite.—App. II., p. 14.

Cuprovanadite.—App. II., p. 15.

Cuspidine. *Scacchi*, Rend. Accad. Napoli, Oct., 1876; Z. Kryst., i., 398, 1877. Orthorhombic. In spear-shaped crystals, formed of two pyramids, 1 and $2\text{-}\frac{2}{3}$, with also $1\text{-}\breve{\imath}$ and $i\text{-}\breve{\imath}$. $1 \wedge 1 = 112° \, 3'$ and $77° \, 50'$ terminal, and $146° \, 30'$ basal. $1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath} = 40° \, 33'$. $\dot{c} : \bar{b} : \breve{a} = 1{\cdot}9376 : 1 : 0{\cdot}7173$. Cleavage in one direction (basal). H. = 5–6. G. = 2·853–2·860. Color pale rose red. Contains SiO_2, CaO, F, and CO_2, the last probably from incipient alteration; composition stated to be perhaps Ca_2SiO_4, with about one-third of the lime replaced by CaF_2, but analysis not given. B. B. fusible with difficulty. Readily soluble in dilute acids. From Vesuvius. Named in allusion to the spear-shaped crystals. [A more complete chemical examination is to be desired.]

Vom Rath has described crystals of a mineral which resembled cuspidine, but which could not be positively identified with it (Ber. nied. Ges. Bonn, Feb. 7, 1881). He has since shown that this mineral is not cuspidine. He has also made a more exact determination of the form of the original cuspidine. It is monoclinic with c (vert) : b : $\breve{a} = 1{\cdot}9623 : 1 : 0{\cdot}7247$, and $\beta = 90° \, 55' \, 41''$. The crystals are twins, which Scacchi suggested might be the case. Ber. nied. Ges. Bonn, Nov. 7, 1881.

Cyanite, Min., p. 375; App. II., p. 14.—The hitherto imperfectly known crystalline form of cyanite has been fully described by *Bauer* (ZS. G. Ges., xxx., 283, 1878; xxxi., 244, 1879; xxxii., 717, 1880); and *vom Rath* (Z. Kryst., iii., 187, 1878; v., 17, 1880). See also *Mallard* (Bull. Soc. Min., ii., 9, 1879).

Made artificially, *Frémy* and *Feil*, C. R., lxxxv., 1032, 1877.

Pseudomorph from Pregratten, Tyrol, *Böhm*, Min. Petr. Mitth., ii., 522, 1879.

Anal., North Thompson R., British Columbia, *Hoffmann*, Geol. Canada, 1880.

Cymatolite.—See *Spodumene*, p. 112.

Cyprusite. *P. F. Reinsch*, Proc. Roy. Soc., xxxiii., 119, 1881. A supposed new iron sulphate, of very doubtful character. Occurs in large quantities, but in an impure condition, incrusting the surface of a hill in the western part of the island of Cyprus. Soft, chalk-like. Color yellowish; in powder intense sulphur yellow. H. = 2. G. = 1·7. Slightly soluble in water, soluble in boiling HCl, leaving a siliceous residue. An approximate analysis gave: SO_3 21·5, Fe_2O_3 (Al_2O_3 tr.) 51·5, insol. siliceous substance 25, H_2O (hygroscopic) 2 = 100. Contains a large percentage of well preserved siliceous shells of microscopic Radiolaria.

Cyrtolite, Min., p. 275.—A mineral regarded as related to cyrtolite by *Nordenskiöld* (Geol. För. Förh., iii., 229, 1876), has the following characters: In tetragonal crystals (1 and $i\text{-}i$), resembling dodecahedrons. Color yellow to yellowish brown. Translucent. H. = 5·5–6. G. = 3·29. Analysis: SiO_2 27·66, ZrO_2 (with a little Al_2O_3) 41·78, Er_2O_3, Y_2O_3 8·49, Ce_2O_3 3·98, CaO 5·06, MgO 1·10, H_2O 12·07, FeO tr. = 100·14. Occurs with fergusonite, arrhenite, xenotime, at Ytterby, Sweden.

Damourite.—See *Mica Group*, p. 77.

Danaite.—See *Arsenopyrite*, p. 10; and App. II., p. 15.

DANALITE, Min., p. 265.—A mineral occurring in isometric octahedrons with magnetite and quartz, at the iron mine, Bartlett, N. H., is referred to danalite by *Wadsworth* (Proc. Bost. Soc. Nat. Hist., xx., 284, 1879). All the characters so far as observed agreed with that species, and the result of the blowpipe examination seems to set the matter above doubt.

DANBURITE, Min., p. 299.—From Russell, N. Y., described by *G. J. Brush* and *E. S. Dana* (Am. J. Sc., III., xx., 111, 1880; or Z. Kryst., v., 188). The crystals belong to the orthorhombic system (not triclinic), and are closely homœomorphous with topaz; $I \wedge I =$ 122° 52′, $4\text{-}\breve{\imath} \wedge 4\text{-}\breve{\imath} =$ 54° 58′, $1\text{-}\bar{\imath} \wedge 1\text{-}\bar{\imath} =$ 97° 7′. Some of the common and simpler forms are shown in the adjoining figures. Here $l = i\text{-}\breve{2}$, $n = i\text{-}\breve{4}$, $d = 1\text{-}\bar{\imath}$, $w = 4\text{-}\breve{\imath}$, $r = 2\text{-}\breve{2}$. The optic axes lie in the basal plane, the bisectrix normal to the brachypinacoid is negativ and is acute for red ($2V_a =$ 87° 37′), but obtuse for blue ($2V_o =$ 90° 56′); $\beta = 1{\cdot}634$ (L. H. = 7–7·25. G. = 2·986–3·021. Color pale wine yellow, honey yellow to yellowish brown. Transparent. Lustre brilliant, vitreous to greasy (massive). Fracture uneven to subconchoidal. An analysis by Comstock gave:

	SiO_2	B_2O_3	CaO	Al_2O_3 (Fe_2O_3 tr.)	ign.
($\frac{2}{3}$)	48·23	26·93	23·24	0·47	0·63 = 99·50.

Formula, same as that for the original mineral from Danbury, viz.: $CaB_2Si_2O_8 = SiO$ 48·78, B_2O_3 28·46, CaO 22·76 = 100. Occurs in small brilliant crystals imbedded in calcite also in larger crystals in cavities from which the calcite has been weathered out, and massive. Associated minerals, quartz, calcite, mica, pyroxene, titanite.

The optical properties of the danburite from Danbury, Conn., have been examined by Des Cloizeaux (Bull. Soc. Min., iii., 195).

DATOLITE, Min., p. 380; App. II., p. 15.—**Cryst.**, Fossa della Castellina, near Porretta Italy, *Bombicci*, Mem. Acc. Bologna, III., viii., 311, 1877 (Z. Kryst., ii., 505). *Groth*, Min.-Samml. Strassburg, p. 186, 1878. Kuchelbad, near Prague, Bohemia, *Vrba*, Z. Kryst., iv., 358, 1880; Theiss, Tyrol, ib., v., 425, 1881. Niederkirchen, Nahethal, *Lehmann*, Z. Kryst., v., 529, 1881. Andreasberg, *v. Kokscharof*, Min. Russl., viii., 139, 1881.

Thermal and optical properties, *Bodewig*, Pogg. Ann., clviii., 230, 1876. Pyro-electrical properties, *Hankel*, Wied. Ann., vi., 57, 1879.

Anal., Casarza, Liguria, *Issel*, Boll. Com. Geol., 1879, 530. Kuchelbad, near Prague, Bohemia, *Preis*, Z. Kryst., iv., 360, 1880. The datolite described by Smith (App. II., p. 16), as occurring with garnet and vesuvianite, was from San Carlos, Inyo Co., Cal. (Hanks), not from Santa Clara.

DAUBERITE.—App. II., p. 16.

Daubréelite. *J. L. Smith*, Am. J. Sc., III., xii., 109, 1876; xvi., 270, 1878.

Massive; somewhat scaly, structure crystalline. Cleavage in one direction. G. = 5·01. Lustre metallic, brilliant. Color black. Streak black. Brittle. Fracture uneven. Not magnetic. Composition (analogous to spinel group) $FeS + Cr_2S_3 = FeS$ 30·45, Cr_2S_3 69·55 = 100. Analysis:

	S	Cr	Fe			
($\frac{1}{3}$)	42·69	35·91	20·10	=	98·70,	or,
	43·26	36·38	20·36	=	100.	

B. B. infusible, loses lustre and (R. F.) becomes magnetic. With borax reacts for chromium. Not attacked by cold nor by hot hydrochloric acid, but completely dissolved in nitric acid, without the liberation of free sulphur.

Occurs associated with troilite, on the borders of troilite nodules, or as minute veins running across them, in the meteoric irons, from Cohahuila, Mexico. Also identified in the iron of Toluca, Mexico, of Sevier, Tenn., and of Cranbourne, Australia. Named after M. Daubrée, of Paris.

The name schreibersite was given by Shepard to a supposed chromium sesquisulphide, occurring in the Bishopville meteorite (Am. J. Sc., II., ii., 383, 1846): the name was afterward changed by Haidinger to shepardite.

Daubreite. *I. Domeyko*, C. R., lxxxii., 922, 1876; Min. Chili, p. 297, 1879.

Amorphous; structure compact, earthy, in part fibrous. H. = 2–2·5. G. = 6·4–6·5. Color yellowish to grayish white. Opaque.

Composition—$4(Bi_2O_3) + Bi_2Cl_6 = Bi_2O_3$ 76·16, Bi_2Cl_6 23·84 = 100. Analysis, Domeyko (l. c.): Bi_2O_3 89·60, Cl 7·50, H_2O 3·84 (?), Fe_2O_3 0·72, or Bi_2O_3 72·60, Bi_2Cl_6 22·52, H_2O 3·84, Fe_2O_3 0·72 = 99·68. In the closed tube gives off acid water, and becomes grayish in color; but on continued heating below fusion turns yellow again. B. B. colors the flame slightly blue; in very thin splinters fuses on the end instantly, the fused part becoming black and compact. Soluble in hydrochloric acid in the cold without residue, the solution having a more or less yellow color.

Occurs at the Constancia mine, Cerro de Tazna, Bolivia. Named after M. Daubrée, of Paris. Daubreite is related to the artificial compounds $2(Bi_2O_3) + Bi_2Cl$ and $6(Bi_2O_3) + Bi_2Cl_6$.

Davreuxite. *De Koninck*, Bull. Ac. Roy. Belg., II., xlvi., 240, 1878.

Orthorhombic (on optical grounds). Resembles asbestos. In aggregates of slender transparent acicular crystals, light extinction parallel and perpendicular to longitudinal direction. Cleavage transverse to needles(?). Color white, with a tinge of flesh red. Analysis of material free from impurity, except quartz:

	SiO_2	Al_2O_3	MnO	MgO	H_2O	
(⅔)	55·94	33·59	5·25	1·10	4·19	Fe_2O_3 or FeO tr. = 100·07.

The amount of quartz was determined as from 13 to 18 p. c.; in the above analysis 16·63 p. c.; and the remainder corresponds approximately to the formula $H_4(Mn, Mg)[Al_2]_3Si_6O_{24}$, which requires: SiO_2 46·89, Al_2O_3 40·19, MnO 6·93, MgO 1·30, H_2O 4·69 = 100. B. B. infusible; with soda a manganese reaction; with cobalt solution a blue color. Slightly attacked by acids. Occurs in quartz veins in the Ardennes schists, at Ottré, Belgium. Named after M. Ch. Davreux.

DAVYNE, Min., p. 328.—Relation to cancrinite and microsommite, *Rauff*, Z. Kryst., ii., 478, 1878.

DAWSONITE, App. II., p. 16.—Optical examination, *Des Cloizeaux*, Bull. Soc. Min., i., 8, 1878.

Occurs in the province of Siena, Pian Castagnaio, Tuscany, according to *Chaper* (Bull. Soc. Min., iv., 155, 1881). Found in thin plates, radiated, and formed of fine fibres in a quartzose rock, impregnated with dolomite, in part argillaceous; associated with calcite, dolomite, pyrite, fluorite, and cinnabar. An analysis by Friedel (ib., iv., 28) afforded: (⅔) CO_2 29·09, Al_2O_3 35·89, Na_2O 19·13, H_2O 12·00, MgO 1·39, CaO 0·42; formula $Na_2[Al_2]C_2O_8, 2H_2O$ or $3Na_2CO_3 + Al_2C_3O_9 + 2[Al_2]H_6O_6$, which requires: CO_2 30·4, Al_2O_3 35·6, Na_2O 21·5, H_2O 12·5 = 100.

Recently found at the Montreal reservoir, Canada, *Harrington* (Can. Nat., x., 1881). Analysis, after deducting impurities, principally calcite: CO_2 27·78, Al_2O_3 36·12, Na_2O 22·86, H_2O 13·24 = 100.

DECHENITE.—Min., p. 609; App. II., p. 16.

DELAFOSSITE.—App. II., p. 16.

DELESSITE, Min., p. 497; App. II., p. 16.—Analyses of several related minerals, Scotland, *Heddle*, Trans. Soc. Edinb., xxix., 81, 1879.

A blackish green chloritic mineral, filling cavities in eruptive rocks in the Thüringer Wald, gave Pufahl (G. = 2·886):

SiO_2	TiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	K_2O	Na_2O	P_2O_5	SO_3	CO_2	H_2O	
28·79	0·18	16·74	4·83	18·30	0·81	16·62	0·98	0·28	0·24	0·08	0·26	0·35	12·25	= 100·21.

For this the formula is calculated $R_7[R_2]_2Si_6O_{22} + 7$ aq. Weiss proposes the name **SUB DELESSITE** for varieties of delessite which show but little Fe_2O_3, and much FeO. ZS. G. Ges., xxxi., 801, 1879.
See also *Diabantite*, p. 37; *Hullite*, p. 60, etc.

DELVAUXITE, Min., p. 583.—Ausstrich, Bohemia, occurrence and composition, *Vala* and *Helmhacker*, J. Min., 1875, 317. Visé, Belgium, *Jorissen* finds 0·30 As_2O_5 and 0·10 V_2O_6, and deduces the formula $[Fe_2]_3P_4O_{19}$, $15H_2O$, or if the water lost by desiccation at ordinary temperatures is included, the same with 11aq additional. Mem. Soc. Geol. Belg., vi., 38, 1879.

DERNBACHITE, App. II., p. 16.—See *Beudantite*, p. 15.

DESCLOIZITE, Min., p. 609; App. II., p. 16.—Cryst. description, probably monoclinic, Venus mine, Department de Minas, and other localities in the Sierra de Cordoba, Argentine Republic, *Websky*, Z. Kryst., v., 542, 1881 (Ber. Ak. Berlin, 1880, 672).
Analyses, Cordoba: 1, dark brown crystals, Rammelsberg; 2, Döring:

	V_2O_5	As_2O_5	PbO	ZnO	FeO	MnO	CuO	H_2O	Cl	
1. G. = 6·080 ([illegible])	22·74	....	56·48	16·60	....	1·16	....	2·34	0·24	= 99·56.
2. ([illegible])	21·41	0·27	56·20	17·08	0·97	0·58	0·28	2·35	0·26	insol. 0·47 = 99·82.

In light brown crystals (G. = 5·915) Rammelsberg obtained PbO 54·35, ZnO 20·93. These analyses lead to the formula $R_4V_2O_9$, H_2O or $R_3V_2O_8 + RH_2O_2$ (Ber. Ak. Berlin, 1880, 652; and ZS. G. Ges., xxxii., 709, 1880). This formula is analogous to that of libethenite, the form of which, as shown by Des Cloizeaux, is also near that of descloizite. On the other hand, Rammelsberg shows that the analysis of Damour (Min., p. 609) after the deduction of the soluble portion reduces to V_2O_5 24·80, PbO 60·40, ZnO 2·25, FeO 1·48, MnO 5·87, CuO 0·99, H_2O 2·43, Cl 0·35 = 98·57, and this corresponds to $R_3V_2O_6$, H_2O, with R = (Mn, Zn, Fe, Cu) : Pb = 1 : 2. Rammelsberg throws some doubt over the correctness of Damour's analysis.
Probable occurrence of descloizite in Arizona, *Silliman*, Am. J. Sc., III., xxii., 201, 1881.

A vanadate, related to descloizite, has been called **BRACKEBUSCHITE** by Döring (Rammelsberg, ZS. G. Ges., xxxii., 711, 1880). The description is as follows:
Occurs in small striated prismatic crystals. Color black. An analysis gave Döring, after the deduction of 4·36 p. c. insoluble: V_2O_5 25·32, P_2O_5 0·18, PbO 61·00, FeO 4·65, MnO 4·77, ZnO 1·29, CuO 0·42, H_2O 2·03 = 99·66. Rammelsberg deduces the formula $R_3V_2O_8 + H_2O$, with Fe : Mn : Pb = 1 : 1 : 4, this gives: V_2O_5 25·45, PbO 62·09, FeO 5·01, MnO 4·95, H_2O 2·50 = 100. Occurs with descloizite and vanadinite, at several localities in the State of Cordoba, Argentine Republic. Named for Dr. D. Luis Brackebusch, of Buenos Ayres. [It is of interest, that the analysis of Döring of this mineral, and that of Damour (as recalculated by Rammelsberg) on the supposed original descloizite, give very nearly identical results; the relation of the two minerals is still uncertain.]

Destinezite. *Forir* and *Jorissen*, Bull. Soc. Geol. Belg., vii., 117, 1881. Announced as an iron phosphate, near delvauxite, containing, according to Jorissen, P_2O_5, As_2O_5, V_2O_5, Fe_2O_3, Al_2O_3, CaO, MgO (tr.), CuO (tr.). Dissolves in hydrochloric acid leaving a slight residue of impurities. Occurs in yellowish white nodular masses of an earthy aspect on the surface, but dull on the fracture. From the ampelite at Argenteau, Belgium. Named after M. Destinez. A complete description is promised.

DEWALQUITE.—App. II., p. 16 (4).

Diabantite. *G. W. Hawes*, Am. J. Sc., III., ix., 454, 1875. DIABANTACHRONNYN, Liebe, Jahrb. Min., 1870 (Appendix I., p. 4).

Massive, with a foliated radiated structure. H. = 1. G. = 2·79. Color dark green. Strongly dichroic. Analyses by Hawes (l. c.), on separate samples, each proved by the microscope to be homogeneous :

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	Na_2O	H_2O	
1. ($\frac{2}{3}$)	33·24	11·07	2·26	25·11	0·41	16·51	1·11	0·25	9·91	= 99·87.
2. ($\frac{1}{2}$)	33·68	10·84	2·86	24·33	0·38	16·52	0·73	0·33	10·02	= 99·69.

These analyses give a quantivalent ratio of R : [R_2] : Si : H = 4 : 2 : 6 : 3, or that of a unisilicate. This corresponds to the formula $R_{12}[R_2]_2Si_9O_{36}$ + 9aq, which is near to that of pyrosclerite. Occurs filling amygdaloidal cavities in the trap of the Farmington Hills, Conn.

The above mineral is similar to the diabantachronnyn of Liebe, in mode of occurrence and in composition ; Hawes suggests the name diabantite as a substitute for the earlier name. It is also very near to Wiik's euralite (App. I., p. 6). These and several other similar minerals, epichlorite, hullite, etc., may fairly be classed with delessite, Min., p. 497.

DIADOCHITE, Min., p. 588.—Anal., Peychagnard, Isère, *Carnot*, Bull. Soc. Min., iii., 39, 1880 ; Védrin, Belgium, Bull. Soc. Geol. Belg., vii., 114, 1881.

DIALLAGE.—See *Pyroxene*, p. 100.

DIALOGITE.—See *Rhodochrosite*, p. 103.

DIAMOND, Min., p. 21; App. II., p. 16.—Cryst., *Rose-Sadebeck*, Abh. Akad. Berlin, 1876, 85 (Z. Kryst., ii., 93, 1877), and ZS. G. Ges., xxx., 605, 1878. *Hirschwald*, Z. Made artificially, *J. B. Hannay*, Proc. Roy. Soc., xxx., 188, 450, 1880.

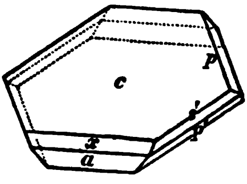
DIAPHORITE.—App. I., p. 4; see also *Freieslebenite*, p. 48.

DIASPORE.—Min., p. 168; App. II., p. 17.

Dickinsonite. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., III., xvi., 114, 1878.

Monoclinic; pseudo-rhombohedral. Axes, $\dot{c} : \dot{b} : \dot{a} = 0·6917 : 0·5773 : 1$; $\beta = 61° 30'$. Observed planes (see figure) : *O* (*c*), $i\text{-}\grave{i}$ (*b*), $i\text{-}i$ (*a*), 1 (*p*), 2 (*s*) — 3-*i* (*x*). $I \wedge I = 66° 36'$, $c \wedge a = 118° 30'$, $c \wedge x = 137° 30'$, $c \wedge p = 118° 52'$, $c \wedge s = 97° 58'$. Crystals rare, tabular in habit, with triangular striations on basal plane; commonly foliated to micaceous. Massive ; also curved lamellar, radiated or stellated. Cleavage : basal perfect.



H. = 3·5–4. G. = 3·338–3·343. Lustre vitreous, on cleavage face somewhat pearly. Color olive to oil green, in masses dark grass green. Streak nearly white. Transparent to translucent. Fracture uneven. Brittle. Planes of light-vibration parallel (grass-green) and normal (yellow-green) to edge *c*/*a* in basal section.

Composition : $4R_3P_2O_8$ + 3aq. If R = Mn : Fe : Ca : Na_2 = 5 : 2½ : 3 : 1½, percentage composition : P_2O_5 40·05, FeO 12·69, MnO 25·04, CaO 11·85, Na_2O 6·56, H_2O 3·81 = 100.

Analyses: 1, 2, by S. L. Penfield; 1, after deduction of impurities, viz., 3·30 p. c. quartz and 6·89 p. c. eosphorite; 2, after deducting 1·89 p. c. quartz, 6·89 p. c. eosphorite.

	P_2O_5	FeO	MnO	CaO	Li_2O	Na_2O	K_2O	H_2O	
1.	39·36	12·40	25·10	13·36	0·03	5·25	0·89	3·86	= 100·25.
2.	39·53	11·90	23·96	[14·98]	0·24	4·78	0·73	3·88	= 100·00.

In the closed tube gives water, the first portions of which are neutral, but the last portions react faintly acid; the residue is magnetic. Fuses in the naked lamp-flame, and B. B. in the forceps colors the flame at first green then greenish yellow; reacts for iron and manganese with the fluxes. Soluble in acid.

Occurs at Branchville, Fairfield Co., Conn., intimately associated with eosphorite, triploidite, and other species in nests in a vein of albitic granite. Often disseminated in minute plates through massive eosphorite, giving it a green color; similarly imbedded in lithiophilite. Named after Rev. Wm. Dickinson, formerly of Redding.

Dietrichite. *V. Schröckinger*, Verh. G. Reichs., 1878, 189. *Arzruni*, Z. Kryst., vi., 92, 1881. In fine fibrous, tufted forms, as an efflorescence or incrusting. Monoclinic (?), Arzruni. H. = 2. Lustre silky. Color dirty white to brownish yellow. Easily soluble in water; taste like vitriol. B. B. fusible. Composition $(Zn,Fe,Mn)SO_4 + Al_2S_3O_{12} + 22aq$. Analysis by Dietrich:

SO_3	Al_2O_3	ZnO	FeO	MnO	MgO	H_2O	
35·94	10·92	3·70	3·11	1·74	0·33	44·38	= 100·12.

A recent formation (within 14 years) in an abandoned working at Felsőbanya, Transylvania. [Belongs with the related alums, mendozite, bosjemanite, halotrichite, etc.]

DIOPSIDE.—See *Pyroxene*, p. 100.

DIMORPHITE.—Min., p. 28; App. II., p. 17.

DIOPTASE, Min., p. 401; App. II., p. 17.—**Cryst.**, *v. Kokscharof*, Min. Russl., vi., 285. 1875; vii., 218, 1878. Chili, *vom Rath*, Z. Kryst., v., 257, 1880; *Bauer*, ZS. G. Ges. xxxii., 714, 1880. [Bauer states that the reported occurrence of dioptase in Nassau is a mistake, see Syst. Min., p. 402; Text-Book, p. 279.]

DOLEROPHANITE.—App. II., p. 17.

DOLOMITE, Min., p. 68; App. II., p. 17.—**Cryst.**, Bex, Switzerland, *v. Kokscharof*, Min. Russl., vii., 1, 1875; Bull. Ac. St. Pet., xxi., 47, 1875. Binnenthal, etc., *Groth*, Min.-Samml. Strassburg, p. 127, 1878.

Relation to the other rhombohedral carbonates discussed, *Tschermak*, Min. Petr. Mitth., iv., 99, 1881.

Anal., Bleiberg, Carinthia, *von Zepharovich*, Z. Kryst., iii., 100. Anal. of var. miemite (by John), from Zepce, Bosnia, *F. v. Hauer*, Verh. G. Reichs., 1879, 121.

Origin of dolomite discussed, *Doelter* and *Hoernes*, Jahrb. G. Reichs., xxv., 293, 1875; *Hoppe-Seyler*, ZS. G. Ges., xxvii., 495, 1875.

DOMEYKITE.—Min., p. 36; App. II., p. 17.

DOPPLERITE, Min., p. 749.—A black gelatinous hydrocarbon, related to dopplerite, is described by *T. Cooper* (Eng. Min. Journ., Aug. 13, 1881), as found in a stratum of muck below a peat bed at Scranton, Penn. More particularly described by *H. C. Lewis* (Am. Phil. Soc. Philad., Dec. 2, 1881). When first found it was jelly-like in consistency, but on exposure to the air it becomes tougher and is elastic, somewhat like india-rubber, and finally when quite dry it is brittle and nearly as hard as coal. Only partially dissolved in hot alcohol, but completely in caustic potash. When dry burns with a yellow flame. Analysis by J. M. Stinson, of material dried at 100° C., gave: C 28·99, H 5·17, N 2·46, O 56·98, ash 6·40 = 100; for which the empirical formula $C_{10}H_{22}O_{15}$ is calculated. Lewis suggests that the various allied jelly-like hydrocarbons may be grouped together under the name PHYTOCOLLITE (φυτόν, κόλλα, or *plant jelly*), but the new name is hardly needed.

DUDLEYITE.—App. II., p. 18.

DUFRENITE, Min., 583; App. II., p. 18.—**Anal.**, Dept. of Freirina, Atacama, *Domeyko*, Min. Chili, 3d ed., p. 161, 1879. From the Rothläufchen mine, near Waldgirmes (kraurite), *Streng*, J. Min., 1881, i., 110.

In radiated coarsely fibrous masses of a dark greenish-brown color, forming an irregular bed of about 10 inches in depth, underlying limonite, in Rockbridge Co., Va.; anal. by J. L. Campbell: P_2O_5 31·76, Fe_2O_3 50·85, Al_2O_3 0·21, FeO 6·14, MnO 0·40, CaO 1·12, MgO 0·76, H_2O 8·53, insol. 0·12 = 99·89. Am. J. Sc., III., xxii., 65, 1881. The same occurrence was earlier analyzed by *Massie* (Ch. News, xlii., 24, 181, 1880), and with almost identical results.

DUFRENOYSITE.—Min., p. 92; App. II., p. 18.

Dumortierite. *Gonnard*, Bull. Soc. Min., iv., 2, 1881; *Bertrand*, ib., iii., 171; and iv., 9; *Damour*, ib., iv., 6.

Orthorhombic (on optical grounds). Occurs in minute prismatic crystals, always twins, prismatic angle inferred to be about 120°. Biaxial, negative bisectrix parallel to the longitudinal direction of the crystals, axial angle small, dispersion $\rho < v$. Remarkably dichroic; colorless when the crystals are parallel, and deep cobalt blue when perpendicular to the plane of polarization. The phenomenon of *houppes* observed in fragments of ·01 mm. thickness, even more strikingly than in andalusite (Bertrand). G. = 3·36 (see below). Color light blue. Analysis, Damour:

SiO_2	Al_2O_3	Fe_2O_3	MgO	ign
29·85	66·02	1·01	0·45	2·25 = 99·58.

Calculated formula $[Al_2]_4Si_3O_{18}$, which requires: SiO_2 30·40, Al_2O_3 69·60. [The material analyzed was obtained by attacking the granite in which it occurred with a mixture of HF and H_2SO_4. This mineral was then separated from the quartz and other substances undecomposed by the Thoulet liquid. Necessarily, therefore, more or less doubt surrounds the chemical composition; the loss by ignition is also neglected in the formula.] Damour thinks the blue color may be due to blue oxide of titanium. B. B. infusible, loses color on strong ignition; with cobalt solution a beautiful blue, characteristic of aluminum. With salt of phosphorus gives a slightly bluish opaline bead.

Found in fibrous forms imbedded in feldspar in blocks of gneiss at Chaponost, near Lyons, France, original locality probably Beaunan. Named for the palæontologist M. Eugène Dumortier.

Duporthite, *J. H. Collins*, Min. Mag., i., 226, 1877.

In fibrous masses occupying fissures in serpentine. H. = 2. G. = 2·78. Lustre silky. Color greenish to brownish gray. Flexible in thin fibres like asbestos. Analysis gave: SiO_2 49·21, Al_2O_3 27·26, FeO 6·20, MgO 11·14, CaO 0·39, Na_2O 0·49, H_2O 3·90, do. hygroscopic 0·68 = 99·27. About half the water goes off only at an elevated temperature. A relation to neolite (Min., p. 406), is suggested. From Duporth, near St. Austell, Cornwall. [Needs further examination.]

DURANGITE, App. I., p. 4.—Des Cloizeaux has investigated the crystalline form and optical properties (Ann. Ch. Phys., V., iv., 401, 1875). An analysis by G. W. Hawes (*Brush*, Am. J. Sc., III., xi., 464, 1876), of small dark-colored crystals (G. = 4·07, other light-colored crystals gave G. =3·937), afforded:

As_2O_5	Al_2O_3	Fe_2O_3	Mn_2O_3	Na_2O	Li_2O	F
53·11	17·19	9·23	2·08	13·06	0·65	7·67* = 102·99, deduct 3·23 O cor- [responding to F = 99·76.

* A second determination gave F = 7·49.

This gives the atomic ratio $R : [\overset{v}{R}_2] : As = 2 : 1 : 2$; the ratio of $O : F = 4·7 : 1$. The formula may be written $\overset{i}{R}_2 [\overset{vi}{R}_2] As_2 (O, F_2)_5$ or nearly $[R_2] As_2O_8 + 2\overset{i}{R}F$; which is analogous, as remarked by Brush (l. c.), to amblygonite, to which, however, in form and optical characters it has apparently no relation (Des Cl.).

Durangite is described by H. G. Hanks (Am. J. Sc., III., xii., 274, 1876), as occurring at the Barranca tin mine, eighteen miles north-east of Coneto, State of Durango, and about ninety miles north-east of the city of Durango. The mineral is found not with the stream tin, but in a vein four to six inches in thickness; the crystals are sometimes attached to the walls of the vein (here the large, light, orange-colored variety, App. I., p. 4), sometimes with cassiterite in the white pulverulent matter which fills the veins (small, dark-colored variety, see above). The largest crystal found was 19 mm. long, 11 mm. thick, and weighed 3·022 grams.

Dürfeldtite. *Raimondi*, Minéraux du Pérou, p. 125, 1878.

In masses with indistinct fibrous structure, also in fine needles. H. = 2·5. G. = 5·40. Color light gray. Lustre metallic. Associated with quartz as gangue. After deduction of impurities (31·31 p. c. gangue), the composition is:

S	Sb	Pb	Ag	Cu	Fe	Mn
24·15	30·52	25·81	7·34	1·86	2·24	8·06 = 100.

For this the formula $3RS + Sb_2S_3$ is deduced. B. B. on charcoal gives off antimonial fumes, gives a lead coating, and leaves a globule rich in silver. With borax reacts for manganese. From the Irismachay mine, Anquimarca, province Cajatambo, Peru. Named after M. R. Dürfeldt. [This mineral is very near stylotypite, but differs in containing lead instead of copper. An analysis of the pure mineral is to be desired.]

Duxite. *Dölter*, Verh. G. Reichs., 1874, 145. A resin from the lignite of Dux, Bohemia. Opaque. Color dark brown. G. = 1·133. Melts at 246°. Fischer obtained besides 2·72 water and 1·94 ash: C 78·25, H 8·14, O 13·19, S 0·42 = 100. Near walchowite, Min., p. 741.

Dysanalyte. *A. Knop*, Z. Kryst., i., 284, 1877. PEROFSKITE of former writers.

Isometric; in cubes. Cleavage cubic. G. = 4·13. Color black. Analyses: 1, 2, Seneca (Ann. Chem. Pharm., civ., 371, 1856); 3, Knop; 4, same as 3 after deduction of impurities:

	TiO_2	Cb_2O_5	FeO	MnO	CeO	CaO	Na_2O
1.	58·95	....	6·23	....	....	35·69	.... = 100·87.
2.	59·30	....	5·99	....	....	35·94	.... = 101·23.
3.	40·57	22·73	5·70	0·42	5·58	19·36	3·50 SiO_2 2·31, MgO, K_2O, Al_2O_3 F, tr. = 100·17.
4.	41·47	23·23	5·81	0·43	5·72	19·77	3·57 = 100.

The atomic ratio for $R : Cb : Ti : O = 7 : 2 : 6 : 24$, corresponding approximately to the formula $RCb_2O_6 + 6RTiO_3$. Found in the granular limestone of Vogtsburg, Kaiserstuhlgebirge, Baden. The mineral has previously been called perofskite, but is in fact closely related to pyrochlore (Min., p. 512), and koppite (App. II., p. 33. Named, in allusion to the difficulty of the analysis, from δυςανάλυτος, *hard to undo.*

DYSCRASITE.—Min., p. 35; App. I., p. 5.

DYSODILE, Min., p. 746.—Anal., Church, Ch. News, xxxiv., 155, 1876.

Eggonite. *Schrauf*, Z. Kryst., iii., 352, 1879.

Triclinic. In minute (¼ to 1 mm.) crystals resembling common forms of barite (Min., p. 616, figs. 505 E, F), hence orthorhombic in habit. Closely related in angle to hopeite (Min., p. 544, see also this Appendix, p. 59). H. = 4–5. Color light grayish brown. Streak white. Lustre sub-adamantine. Translucent to transparent. B. B. infusible, becomes gray and opaque. On charcoal with soda a cadmium coating (no zinc observed). With salt of phosphorus a colorless bead enclosing a skeleton of silica. Insoluble in HCl or HNO_3. Regarded as essentially a silicate of cadmium.

Occurs on and implanted in crystallized calamine, which in turn fills cavities in smithsonite; the last mineral is massive, coarse granular, and of a light brown color, and mixed more or less with red clay. The eggonite is so called from ἔγγονος, *grandson*, as being the third generation in the series of zinc-cadmium compounds. From Altenberg. [Needs further examination.]

Ehlite.—Sec *Pseudomalachite*, p. 97.

Eisenbrucit.—See *Brucite*, p. 18.

Ekdemite. *Nordenskiöld*, Geol. För. Förh., iii., 379, 1877.

Tetragonal (?). Massive, coarsely granular: also as a crystalline incrustation. Cleavage: basal, nearly perfect. Optically uniaxial. H. = 2·5–3. G. = 7·14. Lustre on cleavage plane vitreous, on fracture surfaces greasy. Color bright yellow to green. Translucent in thin splinters. Brittle. Composition: $Pb_4As_2O_8 + 2PbCl_2$ = As_2O_3 10·59, PbO 59·67, Cl 7·58, Pb 22·16 = 100. Analysis (l. c.):

As_2O_3	PbO	Cl	Pb		
10·60	58·25	8·00	23·39	=	100·24.

Fuses easily to a yellow mass, with the loss of lead chloride as a white sublimate; gives a lead coating on charcoal. Soluble readily in nitric or warm hydrochloric acid.

Found at Långban, Wermland, Sweden, in small granular masses, imbedded in a yellow manganesian calcite; also as an incrustation. Named from ἔκδημος, *unusual*.

A mineral of similar appearance, also a compound of arsenic, lead, and chlorine, having the same pyrognostic characters, occurs at Långban, as small lemon yellow grains in calcite. Held to be orthorhombic on basis of crystalline form and optical character. $O \wedge 1$ = 114° 36′, $1 \wedge 1$ = 101° ′28; but as Groth shows (Z. Kryst., ii., 307), these angles give a ratio 1 : ·967 for the lateral axes, so that it may be identical with ekdemite, and not as Nordenskiöld suggests, a dimorphous form.

Elæolite.—See *Nephelite*, p. 84; and App. II., p. 18.

Eleonorite.—See *Beraunite*, p. 13.

Elroquite. *C. U. Shepard*, Min. Contr., 1877.—An apple green to gray, massive substance; translucent to nearly opaque. H. = 6. G. = 2·35–2·40. Composition: SiO_2 16·4, Al_2O_3 16·4, Fe_2O_3 13·8, H_2O 21·8 [P_2O_5 32·00 by difference] = 100. Regarded as a hydrosilicate of Al_2O_3 and Fe_2O_3, mixed with opaline silica and a supposed chromium phosphate, to which "the green color was found to be due." To the chromium phosphate the name PHOSPHOCHROMITE is given [see App. I., p. 9]. From the Island of Elroque, Caribbean Sea. [The description of the mixture is so incomplete that the existence of the supposed species cannot be regarded as proved.]

Embolite, Min., p. 115; App. II., p. 18.—A mineral from the silver mines in the Troitzker Bezirk, Orenburg, gave *W. von Beck* (J. Min., 1876, 165): Br 28·44, Cl 8·21, Ag 63·35 = 100, or AgBr 66·83, AgCl 33·17 = 100, which corresponds to 3AgBr + 2AgCl. It occurs in minute octahedral crystals, and in thin crusts.

Emerald.—See *Beryl*, p. 13.

Emplectite, Min., p. 86; App. II., p. 18.—**Anal.**, Aamdal, Thelemarken, Norway, *Daw*, Ch. News, xl., 225, 1879.

Enargite, Min., p. 107; App. II., p. 18.—**Cryst.**, Matzenköpfl, near Brixlegg, Tyrol, *von Zepharovich*, Z. Kryst., iii., 600, 1879. In compound crystals, twins and star-shaped threelings, twinning plane i-$\frac{3}{2}$, Argentine Republic, *vom Rath*, Z. Kryst., iv., 426. Also from Mancayan, Luzon, twins, etc., *Zettler* (Klein), J. Min., 1880, i., 159 (ref.).

Anal., quoted by Brackebusch, Min. Repub. Argentina, 49. 1879.

Occurrence in Mexico, *Burkhart*, Naturaleza, iii., 336, 1875.

See also *Clarite*, p. 27, *Famatinite*, p. 45.

ENSTATITE, Min., p. 208; App. II., p. 18.—**Cryst.**, Kjörrestad, near Bamle, Norway, in enormous crystals, with analyses, *Brögger* and *vom Rath*, Z. Kryst., i., 18, 1877. Gröditzberg, near Liegnitz, Silesia, cryst. and optical exam., *v. Lasaulx*, J. Min., 1878, 678. Snarum, pseudomorphous crystals, *Seligmann*, Z. Kryst., iii., 81, 1878.
Anal., Georgia, *König*, Proc. Acad. Nat. Sc. Philad., 1877, 198.

Enysite, *Collins*, Min. Mag., i., 14, 1876; *C. Le Neve Foster*, ibid., p. 9.
Forms a bluish green stalagmitic crust. H. = 2–2·5. G. = 1·59. An analysis gave: SO_3 8·12, Al_2O_3 29·85, CuO 16·91, CaO 1·35, SiO_2 3·40, CO_2 1·05, H_2O (over H_2SO_4 after 3 days) 14·04, at 150° C. 18·21, at a red heat 7·17, Fe_2O_3, Cl, Na_2O tr. = 100·10. Compare analyses by Flight (J. Ch. Soc., Jan., 1871) and Pisani (Phil. Mag., Ap., 1868).
Found at St. Agnes, Cornwall, in one of the caves at the old quay. Named after J. S. Enys, F. G. S. [A most improbable compound. Groth shows that it is to be regarded as merely a mechanical mixture (Z. Kryst., i., 75).]

EOSITE.—App. I., p. 5.

Eosphorite.—See *Childrenite*, p. 24.

EPIBOULANGERITE.—App. I., p. 5.

EPIDOTE, Min., p. 281; App. II., p. 18.—**Cryst.**, *v. Kokscharof*, Min. Russl., vi., 297, 1874. Heponselkä, Finland, *Wiik*, Œfv. Finsk. Vet. Soc., xix., 69, 1876–7. Optical exam., *Fouqué-Lévy*, Ann. Min., VII., xii., 484, 1877, *Groth*, Min.-Samml., Strassburg, p. 195, 1878. Analyses and discussion of composition of the species of the epidote group, *Laspeyres*, Z. Kryst., iii., 525, 1879. The doubts suggested by Laspeyres in regard to the correctness of the accepted formula $H_2Ca_4[Al_2]_3Si_6O_{26}$ are answered by *Tschermak* and *Šipöcz*, Ber. Ak. Wien, lxxxii., 141, 1880, and still further by *Ludwig*, Min. Petr. Mitth., iv., 153, 1881.

EPIGENITE.—App. I., p. 5.

EPIPHANITE.—App. I., p. 6.

EPISTILBITE, Min., p. 443; App. II., p. 19.—*Des Cloizeaux* finds epistilbite to be monoclinic in optical characters (Bull. Soc. Min., ii., 161, 1879). A similar result is reached by *Tenne* (J. Min., 1879, 840; 1880, i., 43), who discusses fully the crystalline form. He also quotes an analysis by Jannasch, SiO_2 58·55, Al_2O_3 17·15, CaO 8·99, H_2O 15·41 = 100·10, which corresponds nearly to the accepted formula $Ca[Al_2]Si_6O_{16} + 5aq$.
Found by Seligmann with heulandite, stilbite, etc., at Viesch, Canton Wallis, Switzerland, *Tenne*, J. Min., 1880, i., 285.

Tenne has examined the PARASTILBITE of von Waltershausen, and refers it with little question to epistilbite, J. Min., 1881, ix., 195.

Lüdecke finds that REISSITE (App. I., p. 14) is nearly identical in form with epistilbite (monoclinic), so that it should probably be united to that species; it differs only in hardness, and in that it is said to contain alkalies, J. Min., 1880, ii., 200; 1881, i., 162.

EPSOMITE, Min., p. 643.—Argentine Repub., analyses quoted by *Brackebusch*, Min. Argentin., 73, 1879.

A massive variety is called REICHARDTITE by Krause (Arch. Pharm., III., v., 423, and vi., 41, in Z. Ges. Nat., II., x., 554)—[the new name, however, is most unnecessary]. Crystalline, granular or foliated. Cleavage easy. G. = 1·6–1·7. Transparent to translucent. Fracture conchoidal. The analyses agree closely with the formula $MgSO_4 + 7aq$, viz.:

		SO_3	MgO	H_2O		
1. Stassfurt	(?)	39·28	9·82	51·17	=	100·22.
2. Leopoldshall		39·31	9·77	51·20	=	100·28.

Occurs forming thin layers associated with carnallite, at Stassfurt and Leopoldshall.

ERDMANNITE.—Engström (Inaug. Diss. Upsala, 1877, abstr. in Z. Kryst. iii., 199, 1878) has analyzed a mineral from the Stockö, Norway, which he regards as probably the same as that named erdmannite by Esmark (Min., p. 414, see Berlin, Pogg. Ann., lxxxviii., 162), and also identical with that analyzed by Michaelson and Nobel (Michaelsonite, Min., p. 289). He obtained: SiO_2 25·15, B_2O_3 8·18, ZrO_2 2·14, ThO_2 9·93, Fe_2O_3 3·01, Ce_2O_3 9·00, $Di_2(La_2)O_3$ 8·66, Y_2O_3 1·64, Er_2O_3 0·50, FeO 8·16, CaO 18·78, BeO 3·16, Na_2O 1·02, K_2O 0·42, H_2O 5·25 ± 100. The author writes the formula $R_3SiO_5 + Be_2SiO_5 + 3aq$, and suggests a relation to datolite.

Another mineral related to erdmannite, analyzed by Damour (Ann. Ch. Phys., V., xii., 411, 1877) gave results varying somewhat widely from the above analysis; he found 12·10 p. c. H_2O (see *Homilite*, p. 59).

Erilite. *H. C. Lewis*, Proc. Ac. Nat. Sc. Philad., 1880, 292. Minute acicular crystals, looking like tufts of white wool, observed in a cavity in quartz from Herkimer Co., N. Y.; chemical nature unknown. The cavity also contained a liquid of undetermined character. [A substance of unknown characters, not even proved to be new, does not deserve a name —the practice of provisionally attaching names in such cases is to be condemned.]

Eriochalcite. Copper chloride from Vesuvius (1870), by *Scacchi* (Bull. Soc. Min., i., 132).

ERSBYITE.—Min., p. 361; App. II., p. 19.

ERYTHRITE.—Min., p. 558; App. II., p. 19.

ERYTHROSIDERITE, App. II., p. 19.—Vesuvius, *Scacchi*, Contrib. Min., II., p. 42, 1874. **DOUGLASITE**, from Douglasshall, is $2KCl, FeCl_2, 2H_2O$, *Ochsenius*, *Precht*, Ber. Ch. Ges., xiii., 2328, 1881.

Erythrozincite. *Damour*, Bull. Soc. Min., iii., 156, 1880. Occurs in thin plates apparently crystalline. Color red. Streak pale yellow. Translucent. Contains sulphur, zinc, and manganese, as proved by a qualitative examination on the small amount of material available. B. B. gives sulphurous fumes in the open tube, fuses in the forceps to a blackish slag. Dissolves in nitric acid with the separation of a little sulphur. Occurs in veins of lapis lazuli, from Siberia. *Des Cloizeaux* (ib., iv., 40, 1881) finds that cleavage plates of this mineral show in polarized light a black cross (positive), resembling that of wurtzite, both natural and artificial. He concludes that it is probably a manganesian variety of this mineral.

ESMARKITE.—See *Anorthite*, p. 7; and App. II., p. 19.

ETTRINGITE, App. II., p. 19.—Optically uniaxial, negative, *Bertrand*, Bull. Soc. Min., iv., 84, 1881.

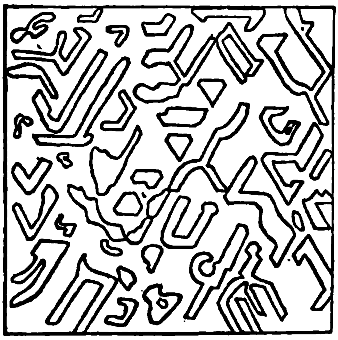
Euchlorite.—See *Mica Group*, p. 77.

EUCLASE, Min., p. 379; App. II., p. 19.—**Cryst.**, ***Kulibin***, Verh. Min. Ges. St. Pet., II., xiv., 147, 1879. Brazil, *Guyot*, Z. Kryst., v., 250, 1880. From the Hohe Tauern, Tyrol, perhaps from Rauris, crystals described by *Becke*, Min. Petr. Mitth., iv., 147, 1881.

Eucrasite. *S. R. Paijkull*, Geol. För. Förh., iii., 350, 1877.
Orthorhombic (?). H. = 4·5–5. G. = 4·39. Lustre greasy. Color blackish brown. Streak

brown. Slightly translucent in thin splinters. Fracture uneven. Brittle. **Analysis**: SiO_2 16·20, TiO_2 1·27, SnO_2 (?) 1·15, ZrO_2 0·60, MnO_2 2·34, ThO_2 35·96, CeO_2 5·48, Ce_2O_3 6·13, La_2O_3 (Di_2O_3) 2·42, Y_2O_3 4·33, Er_2O_3 1·62, Fe_2O_3 4·25, Al_2O_3 1·77, CaO 4·00, MgO 0·95, K_2O 0·11, Na_2O 2·48, H_2O 9·15 = 100·21. The quantivalent ratio for $\overset{II}{R} : [\overset{VI}{R_2}] : \overset{IV}{R} : Si(Ti) : H = 2·18 : 4·47 : 6·67 : 9·14 : 8·13$. B. B. fusible (at 4) on the edges. The borax bead in the R. F. is violet, in the O. F. yellow. In hydrochloric acid partially soluble, with the evolution of chlorine. Completely soluble in sulphuric acid. Occurs near Barkevik, Brevig, Norway. Named from εὖ and κρᾶσις. [This is the mineral which has been referred, with a question, to polycrase, and also to polymignite, Dana, Min., p. 523. It seems, however, to be closely related to thorite, Min., p. 413.]

Eucryptite. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., III., xx., 266, 1880. Hexagonal. Cleavage probably basal. In symmetrically arranged crystals, imbedded in albite (see figure). G. = 2·667. Color white. Composition $Li_2[Al_2]Si_2O_8$, which requires: SiO_2 47·51, Al_2O_3 40·61, Li_2O 11·88 = 100. Gelatinizes in hydrochloric acid.



Eucryptite forms with albite an apparently homogeneous substance, called by the authors "β spodumene;" it is derived from the alteration of spodumene. The microscope shows the two minerals of which this substance is made up, and chemical analysis serves to separate the latter into a soluble portion (eucryptite), and an insoluble portion, albite. This is further explained, with analyses, on p. 113. From Branchville, Conn. Named from εὖ, *well*, and κρυπτός, *concealed*.

EUDIALYTE, Min., p. 248; App. II., p. 19.—Greenland, *v. Kokscharof*, Verh. Min. Ges. St. Pet., II., xiv., 205, 1878; Min. Russl., viii., 29, 1878.

EUDNOPHITE, Min. p. 433.—**Anal.**, *Damour*, Bull. Soc. Min., iv., 239, 1881.

EULYTITE, Min., p. 391; App. II., p. 19.—*Bertrand* regards the apparently tetrahedral crystals as formed of four rhombohedrons of 120°, placed with their vertices at a common point. A section cut parallel to a tetrahedral face exhibits, in converging polarized light, a single negative axis perpendicular to it, Bull. Soc. Min., iv., 61, 1881.

EURALITE.—App. I., p. 6.

EUSYNCHITE, Min., p. 609.—A related mineral from Laurium, Greece, gave *Pisani* (C. R., xcii., 1292, 1881): V_2O_5 25·53, PbO 50·75, CuO 18·40, CaO 1·53, H_2O 4·25 = 100·46, corresponding to $(Pb, Cu)_3V_2O_8$, if the water is neglected. Occurs in crystalline crusts on quartz; color greenish black to olive green.

Another closely related mineral is called TRITOCHORITE by *A. Frenzel* (Min. Petr. Mitth., iii., 506; iv., 97, 1881). Massive, structure fibrous-columnar. Cleavage parallel to fibres, distinct. H. = 3·5. G. = 6·25. Color blackish brown to yellowish brown. **Analysis**:

	V_2O_5	As_2O_5	PbO	CuO	ZnO		
(⅔)	24·41	3·76	53·90	7·04	11·06	=	100·17.

Formula approximately $R_3V_2O_8$, with R = Pb, Cu, Zn. B. B. fuses easily with intumescence, giving off arsenical fumes. On charcoal gives coatings of lead and zinc, and in R. F. a lead globule. Soluble in HNO_3 and in HCl. From "Mexico or South America." Named from τρίτος, *third*, and χωρέω, *to follow*, in allusion to its relation to eusynchite and aräoxene (Rammelsberg, Min. Chem., 2d ed., p. 290, 291).

EUXENITE, Min., p. 521; App. II., p. 20.—**Cryst. form**, *Brögger*, Z. Kryst., iii., 483, 1879.

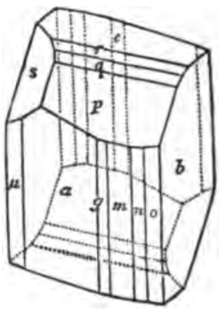
A mineral occurring with samarskite in Mitchell Co., N. C., gave *J. L. Smith* (Am. J. Sc., III., xiii., 365, 1877): Cb_2O_5 54·12, WO_3, SnO_2 0·21, Y_2O_3, Ce_2O_3 24·10, U_2O_3 9·53, CaO 5·53, MnO 0·08, FeO 0·31, H_2O 5·70 = 99·58. G. = 4·593–4·642. Color brownish black to hair brown; translucent in thin fragments; lustre resinous. [Smith calls this euxenite, but that it cannot be; for example, Rammelsberg finds in true euxenite 20–23·5 p. c. TiO_2, and G. = 4·67–5·1.]

Fahlerz.—See *Tetrahedrite*, p. 120.

Fahlunite.—Min., p. 484; App. II., p. 20.

Fairfieldite. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., III., xvii., 359, 1879.

Triclinic. Axes: $\grave{c} : \breve{b} : \bar{a}$ = 0·7065 : 3·5757 : 1·0000 Observed planes (see figure) $i\text{-}\bar{i}$ (*a*), $i\text{-}\breve{i}$ (*b*), O (*c*), $i\text{-}\bar{\frac{3}{2}}'$ (*g*), I' (*m*), $i\text{-}\breve{\frac{3}{2}}'$ (*n*), $i\text{-}\breve{2}$ (*o*), I (*μ*), $-1'$ (*p*), $-\frac{1}{2}'$ (*q*), $-\frac{1}{3}'$ (*r*), $-4\text{-}\breve{4}$ (*s*). Angles *ab* = 78°, *ac* = 92°, *ap* = 123° 30′, *cp* = 147°, *bp* = 101° 30′. Cleavage *b* highly perfect, *a* less so. Usually in foliated to lamellar crystalline aggregates; occasionally curved, foliated, or fibrous, in radiating masses. H. = 3·5 G. = 3·15. Color white to pale straw yellow. Streak white. Lustre pearly to sub-adamantine, on the surface of perfect cleavage (*b*) very brilliant. Transparent. Brittle. The planes of light vibration intersect *a* in lines making angles of 40° and 50° with the obtuse edge *a* / *b*; in the latter, an optic axis is visible toward the edge named. The planes intersect *b* in lines making angles of 10° and 80° with the edge *a* / *b*, the second axis visible in this plane.



Analyses by S. L. Penfield, 1, of a clear transparent variety, filling cavities in reddingite; 2, of the massive, somewhat friable variety:

	P_2O_5	FeO	MnO	CaO	Na_2O	K_2O	H_2O	Quartz		
1.	38·39	5·62	15·55	28·85	0·73	0·18	9·98	1·31	=	100·56.
2.	39·62	7·00	12·40	30·76	0·30	....	9·67	0·55	=	100·30.

The ratio of P_2O_5 : RO : H_2O is 1 : 3 : 2, and the formula $R_3P_2O_8$ + 2aq, with R = Ca : (Mn + Fe) = 2 : 1. This requires: P_2O_5 39·30, FeO 6·64, MnO 13·10, CaO 30·99, H_2O 9·97 = 100. B. B. glows, blackens, and fuses at 4·15 to a dark yellowish brown mass, coloring the flame pale green, with faint reddish yellow streaks on the upper edge. Reactions for iron and manganese with the fluxes. In the closed tube gives off neutral water; turns first yellow, then dark brown, and becomes magnetic. Soluble in HCl and HNO_3. Occurs with other manganesian phosphates at Branchville, Fairfield Co., Conn. In composition fairfieldite is analogous to roselite, p. 105.

Famatinite, App. II., p. 20.—With enargite from Cerro de Pasco, Peru, anal. *Frenzel* (J. Min., 1875, 679) S 33·46, Sb 10·93, As 7·62, Cu 41·11, Fe 6·43 = 99·55, corresponding to the formula $3Cu_2S + (Sb, As)_2S_5$, or that of enargite.

According to *vom Rath* (Z. Kryst., iv., 426), the famatinite from the Argentine Republic, which also occurs with enargite (App. II., p. 20), has the same form and angles as the latter mineral, as was to be expected from the essential identity in composition.

See also *Enargite*, p. 41, and *Clarite*, p. 27.

Faujasite.—Min., p. 433; App. II., p. 20.

Feldspar Group, Min., pp. 335 to 361; and App. II., p. 20.—**Cryst.**, methods of twinning of triclinic feldspars, *vom Rath*, J. Min., 1876, 689.

Microscopic structure, *Rutley*, Q. J. G. Soc., 1875, 479. Optical examination of microcline, orthoclase, and various triclinic feldspars, *Des Cloizeaux*, Ann. Ch. Phys., V., ix., 433, 1876. Cryst. and opt. examination, *Wiik*, Œfv. Finsk. Vet. Soc., xix., 60, 1876–77, giving results similar to those more fully obtained by Schuster (see below). Determination by optical methods in thin rock sections, *Lévy*, Ann. Min., VII., xii., 440 et seq., 1877;

see also *Thoulet*, Ann. Min., xiv., 115 et seq., 1878. Discussion of the specific gravities of the feldspar species, *Goldschmidt*, J. Min., Beil.-Bd., i., 203, 1881.

Schuster (Min. Petr. Mitth., iii., 117, 1880), has carried through a long series of observations as to the optical characters of the triclinic feldspars; and has established the important conclusion that in an optical sense there is the same gradual transition from one extreme (albite), to the other (anorthite), as is observed in the chemical composition. Thus, he finds that the position of the extinction-directions, as observed on the basal and clinodiagonal planes, the position of the axes of elasticity, the dispersion of the axes, and the axial angle, all show this gradual change in the same direction. These conclusions obviously confirm the now almost universally accepted view of Tschermak, that the intermediate triclinic feldspars (plagioclase) are to be regarded as isomorphous mixtures of albite and anorthite.

Mallard (Bull. Soc. Min., iv., 96, 1881), has gone further and shown that by means of formulas deduced by him (ib., p. 71), on the view that in isomorphous mixtures (as of albite and anorthite) each element usually enters without change of its own characters, it is possible to calculate the direction of extinction for the two planes (*O* and *i-ī*): the results of calculation and experiment agree very closely. Experiments by *Fouqué* and *Lévy* (Bull. Soc. Min., iv., 63, 1881), on a series of feldspathic microlites intermediate between albite and anorthite, give results at variance with the above conclusions.

Analyses of feldspars from various localities in Scotland, monograph, *Heddle*, Trans. Roy. Soc. Edinb., xxviii., 197 et seq., 1877; Min. Mag., ii., 36, 1878. From volcanic rocks of the Andes, *vom Rath*, ZS. G. Ges., xxvii., 295 et seq., 1875. Discussion of composition by the same, J. Min., 1875, 397. *Smita*, Min. Mitth., 1877, 265.

Examination of the feldspar pseudomorphs of the Wilhelmsleite, near Ilmenau, *Dalmer*, J. Min., 1878, 225.

Species determined by the flame reactions, *Szabó* (for title see Bibliography in Introduction); determined by their fusibility, *Bischof*, Dingl. Pol. Journ., ccxxii., 319; ccxxiii, 265.

Artificial formation of feldspar species: *Fouqué* and *Lévy*, C. R., lxxxvii., 700, 779; xc., 620, 1880; Bull. Soc. Min., iv., 63, 1881 (see also under *Orthoclase*, p. 87).

Genth (Report Min. Penn., p. 224, 1876) shows that the varieties of orthoclase, called by Lea lennilite and delawarite, are identical; an analysis showed 9·11 K_2O, 4·88 Na_2O. Analysis of Lea's cassinite from Blue Hill, Delaware Co., gave:

		SiO_2	Al_2O_3	Fe_2O_3	BaO	CaO	MgO	SrO	Na_2O	K_2O	ign	
G. = 2·692	(⅓)	62·60	19·97	0·12	3·71	0·19	0·03	tr.	4·43	9·00	0·19	= 100·23.

This feldspar is remarkable for affording 3·7 p. c. BaO, but an optical examination is needed to decide its true relations.

Another feldspar containing barium has been described optically by Des Cloizeaux, and chemically by Pisani (Bull. Soc. Min., i., 84, 1878); locality unknown. Triclinic, with the angle between the cleavage planes = 86° 37′ (near labradorite), in optical relations, approaches oligoclase and albite. An analysis gave:

	SiO_2	Al_2O_3	Fe_2O_3	BaO	CaO	MgO	Na_2O	K_2O	ign	
G. = 2·835	55·10	23·20	0·45	7·30	1·83	0·56	7·45	0·83	3·72	= 100·44.

Quantivalent ratio of R : $[R_2]$: Si = 1 : 3 : 8, or that of hyalophane, giving the formula $(Na_2, Ba)[Al_2]Si_4O_{12}$ [but note the loss of 3·7 p. c.].

See also *albite*, *anorthite*, *labradorite*, *microcline*, *oligoclase*, *orthoclase*.

Fergusonite, Min., p. 524; App. II., p. 21.—New localities: Rockport, Mass., anal. *J. L. Smith*, Am. J. Sc., III., xiii., 367, 1877; Burke Co., N. C., *id.*, Bull. Soc. Min., iii., 195, also *Hidden*, Am. J. Sc., III., xx., 150, 1880. Mitchell Co., N. C., *Shepard*, Am. J. Sc., III., xx., 57.

Ferrite.—App. II., p. 21.

Ferroilmenite.—App. I., p. 6.

Ferrotellurite. *F. A. Genth*, Am. Phil. Soc., xvii., 119, 1877; or Z. Kryst., ii., 8. In delicate radiating tufts, also in very minute prismatic crystals. Color between straw and lemon-yellow inclining to greenish yellow. Contains iron, tellurium. Composition suggested on the basis of a qualitative analysis, $FeTeO_4$. Insoluble in ammonia; soluble in HCl. Found as a coating on quartz associated with native tellurium and tellurite, at the Keystone mine, Magnolia District, Colorado. [Needs further examination.]

FERROTUNGSTEN.—App. II., p. 21.

FIFBROFERRITE, Min., p. 656; App. II., p. 21.—Anal., $[Fe_2]S_2H_4O_{11} + 8aq$, Chili, *Brun*, Z. Kryst., v., 104, 1880.

FIBROLITE, Min., p. 373; App. II., p. 21.—St. Michel, Finland, *F. J. Wiik*, Z. Kryst., ii., 496.

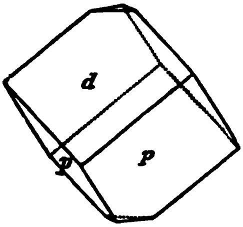
Optical examination, orthorhombic, *Des Cloizeaux*, Bull. Soc. Min., iv., 258, 1881.

FICHTELITE.—Min., p. 785; App. II., p. 21.

Fillowite. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., III., xvii., 363, 1879.

Monoclinic; pseudo-rhombohedral. Axis *c* (vert.) : *b* : *ǎ* = ·8201 : ·5779 : 1; *β* = 89° 51′. Observed planes (see fig.): *O* (*c*), 2-*ĭ* (*d*), 1 (*p*). Angle *cd* = 121° 29′, *cp* = 121° 20′, *pp* = 84° 37′. Cleavage basal, nearly perfect. In granular crystalline masses. H. = 4·5. G. = 3·43. Lustre sub-resinous to greasy. Color wax-yellow, yellowish to reddish brown, colorless. Streak white. Transparent to translucent. Analysis by S. L. Penfield:

	P_2O_5	FeO	MnO	CaO	Na_2O	Li_2O	H_2O	Quartz.
(⅔)	39·10	9·33	39·42	4·08	5·74	0·06	1·66	0·88 = 100·27.



The ratio for $P_2O_5 : RO : H_2O = 1 : 3 : \frac{1}{3}$, and the formula is $3R_3P_2O_8 + aq$. If $R = Mn : Fe : Ca : Na_2 = 6 : 1 : 1 : 1$, this requires: P_2O_5 40·19, FeO 6·80, MnO 40·19, CaO 5·28, Na_2O 5·84, H_2O 1·70 = 100. B. B. fuses at 1·5, with intumescence to a black feebly magnetic mass, coloring the flame momentarily pale green, then intensely yellow. In the closed tube a little neutral water. With the fluxes reactions for manganese and iron. Soluble in HCl and HNO_3.

Occurs with other manganesian phosphates, especially reddingite and triploidite, in a vein of albitic granite at Branchville, Conn. Named after Mr. A. N. Fillow, of Branchville.

FISCHERITE, Min. p. 582.—*Des Cloizeaux*, Verh. Min. Ges. St. Pet., II., xi., 32, 1876; *v. Kokscharof*, Min. Russl., vii., 23.

FLUOCERITE.—Min., p. 126; App. II. p. 21.

FLUORITE, Min., p. 123; App. II., p. 21.—Cryst., Striegau, Silesia, *v. Lasaulx*, J. Min., 1875, 134, and Z. Kryst., i., 359, 1877; Kongsberg, Norway, same, ib., p. 368; Münsterthal, *Klocke*, Ber. Nat. Ges. Freiberg, vi., 461, 1876. Natural etchings on crystalline faces, due to trapezohedron 3-3, *Werner*, J. Min., 1881, i., 14.

"Photo-electricity," *Hankel*, Wied. Ann., ii., 66, 1877. Constants of elasticity, *Klang*, Wied. Ann., xii., 321, 1881.

Dark-colored varieties from Wälsendorf ("antozonite") yield free fluorine on fresh fracture, perhaps from ceric fluoride, *Loew*, Ber. Chem. Ges., xiv., 1144, 1881.

According to Mallard (Ann. Min., VII., x., 115, 1876), fluorite is only pseudo-isometric, the method of grouping of the individual crystals being analogous to analcite (q. v.; also see p. viii).

FORESITE, App. II., p. 22.—Similar to stilbite in optical characters, *Des Cloizeaux*, J. Min., 1876, 640.

Analysis by *Sansoni*: (⅓) SiO_2 49·97, Al_2O_3 24·12, CaO 8·33, Na_2O, K_2O 0·46, H_2O 17·06, MgO tr. = 99·94. He calls attention to the similarity to stilbite, and questions whether the species is really independent of it. Att. Soc. Tosc., iv., 317, 1879.

Franklandite, *Reynolds*, Phil. Mag., V., iii., 284, 1877.
Massive, with fine fibrous structure. H. = 1. G. = 1·65. Color white. An analysis gave:

B_2O_3	CaO	Na_2O	H_2O	(Na, K) Cl	$CaSO_4$ + 2aq.
[43·76*]	12·10*	12·37	27·92	2·41	1·44 = 100.

* Other independent determinations gave B_2O_3 41·81, CaO 11·94, H_2O 27·66.

Deducting impurities, the formula deduced is $Na_4Ca_2B_{12}O_{22}$, $15H_2O$. Slightly soluble in water, readily in dilute HCl and HNO_3. Fuses easily. From Tarapaca, Peru. [Very near ulexite, Min., p. 598.]

FRANKLINITE, Min., p. 152; App. II., p. 22.—Franklin Furnace, N. J., analyses giving the spinel ratio, *Seyms*, Am. J. Sc., III., xii., 210, 1876.

Fredricite.—See *Tennantite*, p. 119.

FREIESLEBENITE, Min., p. 93; App. I., p. 4.—Cryst., twins, Hiendelaencina, Spain, *Bücking*, Z. Kryst., ii., 425, 1878. *Vrba* obtained identical results for the specific gravity of freieslebenite from Hiendelaencina, and diaphorite of Przibram, viz., 6·040; analysis by Morawski, quoted by him, yielded the same result, Z. Kryst., ii., 159, 1878.
Bertrand mentions diaphorite from Zancudo, New Granada, Bull. Soc. Min., iii., 111, 1880.

FRENZELITE.—See *Guanajuatite*, p. 53.

Freyalite. *Esmark; Damour*, Bull. Soc. Min., i., 33, 1878.
Resembles some brown thorites. Scratches glass slightly. G. = 4·06–4·17. Color brown. Streak yellowish gray. Translucent in thin splinters. Lustre resinous. An approximate analysis gave:

SiO_2	Ce_2O_4	La_2O_3, Di_2O_3	ThO_2	$Al_2O_3(ZrO_2?)$	Fe_2O_3	Mn_3O_4	K_2O, Na_2O	H_2O	ign.
20·02	28·80	2·47	28·39	6·31	2·47	1·78	2·33	7·40	0·82 = 100·79.

B. B. swells up but does not fuse. In the closed tube decrepitates, gives off water, and becomes white. With salt of phosphorus in R. F. dissolves, forming an opal-like glass, which in O. F. becomes brown, and on cooling is colorless and translucent. With borax in O. F. gives a transparent brown bead, becoming almost colorless on cooling, and showing in the spectroscope an absorption band on the border of the red and orange (Di). Dissolves readily in acid, giving gelatinous silica. With HCl chlorine is given off. From the neighborhood of Brevig, Norway.

Friedelite. *Bertrand*, C. R., lxxxii., 1167, 1876; Z. Kryst., i., 86.
Rhombohedral; *c* (vert.) = 0·5624. Crystals often tabular. Observed planes *O*, *R*, and *I*, the two last often striated parallel to their intersection-edge. $O \wedge R = 147°$, $R \wedge R = 123° 42'$. Double refraction strong, axis negative. Cleavage basal perfect. Massive, with saccharoidal structure and distinct cleavage, passing into close compact with indistinct cleavage. H. = 4–5. G. = 3·07. Color rose red. Powder pale rose. Transparent-translucent. Optically uniaxial, negative. Analysis (mean of several):

SiO_2	MnO (FeO tr.	MgO, CaO	H_2O
36·12	53·05	2·96	7·87 = 100.

Formula deduced: $Mn_4Si_3O_{10}$, $2H_2O$. B. B. fuses easily to a black glass. Gives off water in the closed tube. Reaction for manganese with the fluxes. In HCl dissolves, forming a jelly. Associated with rhodochrosite and alabandite at the manganese mine of Adervielle, vallée du Louron, Hautes Pyrénées. [The formula may be written $H_4Mn_4Si_3O_{12} = R_2SiO_4$, the composition then corresponds with that of dioptase H_2CuSiO_4, to which it seems to be related in form.]

Frieseite.—See *Sternbergite*, p. 115.

Frigidite.—See *Tetrahedrite*, p. 115.

GADOLINITE, Min., p. 298; App. II., p. 22.—Microscopic examination of specimens from different localities, *A. Sjögren*, Geol. För. Förh., iii., 258, 1877.

Anal., Stora Tuna, *G. Lindström*, Geol. För. Förh., ii., 218, 1874. *Humpidge* and *Burney*, J. Ch. Soc., xxxv., 117, 1879 (Z. Kryst., vi., 94).

GALENITE, Min., p. 40; App. II., p. 23.—**Cryst.**, Freiberg, etc., *Groth*, Min.-Samml. Strassburg, p. 46, 1878. Hesselbach, Westphalia, *vom Rath*, Z. Kryst., iv., 428, 1880. "Schlagfiguren," *Weiss*, ZS. G. Ges., xxix., 209, 1877.

Habach, Salzburg (Bi_2S_3 1·97 p. c., G. = 7.50). Octahedral cleavage very perfect, cubic less so. After ignition cubic cleavage most readily obtained; with interposed twinning lamellæ parallel 3-3, *v. Zepharovich*, Z. Kryst., i., 155, 1877. A crystal (15 grams) with perfect octahedral cleavage has been found by *Brun* on the glacier of Leschant, Mont Blanc, Bull. Soc. Min., iv., 260, 1881.

Recent formation from Bourbonne-les-Bains, *Daubrée*, C. R., lxxx., 604, 1875; lxxxi., 184. Containing selenium, Guanajuato, Mexico, *Navia*, Naturaleza, iv., 42, 1877.

Pseudomorph after staurolite, Brittany, *Firket*, Bull. Soc. Geol. Belg., vi., 152, 1879.

See also *Huascolite*, p. 60.

Galenobismutite. *H. Sjögren*, Geol. För. Förh., iv., 109, 1878.

Massive, compact, sometimes radiated. H. = 3-4. G. = 6·88. Lustre metallic, brilliant. Color tin white. Streak grayish black, shining. Composition $PbBiS_4$, or $PbS + Bi_2S_3$ = S 16·95, Bi 55·62, Pb 27·43 = 100. Analyses (l. c.):

	S	Bi	Pb	Fe		
1.	17·35	54·69	27·65	tr.	=	99·69.
2.	16·78	54·13	27·18	tr	=	98·09.

B. B. reacts for bismuth and lead, fusing easily on charcoal. Dissolves with difficulty in hydrochloric acid, readily in strong nitric acid. Occurs with bismutite at the Kogrufva, Nordmark, Wermland, Sweden. Sometimes carries gold. [The bismuth compound corresponding to zinkenite and sartorite.]

A related mineral, containing a little selenium, is described by *Atterberg* as occurring at Fahlun, Sweden (Geol. För. Förh., ii., 76, 1874), as follows:

Massive. H. = 2-3. Lustre metallic. Color steel gray, becoming slightly reddish. An analysis gave (⅓): Bi 68·40, S 10·39, Se 1·15, Pb 17·90, Fe 1·52, insol. (quartz) 1·60 = 100·96. The calculated formula is Bi_4PbS_4. The substance is regarded as an intimate mixture of native bismuth with a sulphobismutite of lead (PbS, Bi_2S_3). The author adds that such mixtures, containing metallic bismuth, are not uncommon (see *Silaonite*, p. 58).

Another related mineral, also from Fahlun, has been examined by *Nordström* (ib., iv., 268, 1879), containing 4·79-5·11 p. c. Se.

Ganomalite. *Nordenskiöld*, Geol. För. Förh., iii., 121, 1876; 382, 1877.

Massive, without distinct cleavage. Strongly doubly-refracting. Optically biaxial, with very small angle (Des Cloizeaux, Bull. Soc. Min., i., 8, 1878). H. = 4. G. = 4·98. Lustre greasy. Colorless or white, to whitish-gray. Transparent. Composition $(Pb, Mn)SiO_3$; approximate analysis, G. Lindström:

SiO_2	PbO	MnO	CaO	MgO	
34·55	34·89	20·01	4·89	3·68	alkalies, ign. 1·88 = 99·58.

B. B. fuses easily to a clear glass, which in R. F. is colored black by reduced lead. On charcoal with soda a lead globule, and a coating of lead oxide. Easily soluble in nitric acid, with the separation of gelatinous silica.

Occurs very sparingly with tephroite (which it closely resembles), native lead, calcite, and jacobsite, at Långban, Wermland, Sweden. Named from *γάνωμα, brightness.*

Nordenskiöld (p. 384) mentions the occurrence at Långban, of a second lead silicate, very similar in appearance and blowpipe reactions to the above, but with two distinct cleavages, at an angle of 104° 38′. The material available was too scanty for full examination, but he suggests that it may be a more distinctly crystallized variety of ganomalite. [Compare the other lead silicates, *Kentrolite, Hyalotekite, Melanotekite.*]

GARNET, Min., p. 265; App. II., p. 23.—**Cryst.**, Geyer, Saxony, *v. Lasaulx*, J. Min., 1875, 149. As a secondary mineral on trap rock, New Haven, Conn., also anal., *E. S. Dana*, Am. J. Sc., III., xiv., 215, 1877. Pfitschthal, Tyrol, *vom Rath*, Z. Kryst., ii., 173, 1878; Piz Alpetta, Dissentis, Switzerland, *vom Rath*, Z. Kryst., v., 495, 1881.

(Colophonite) possessing double-refraction, and in part, at least, to be referred to vesuvianite, *Wichmann*, Pogg., clvii., 282, 1876; *v. Lasaulx*, J. Min., 1876, 630. Specific gravity determinations, *Church*, Geol. Mag., II., ii., 321, 1875.

W., Sept. 1, Nov. 3, 1880.

Absorption spectrum, *Vogel*, Ber. Chem. Ges., Berlin, x., 373, 1877.

Altered to chlorite, Lake Superior, *Pumpelly*, Am. J. Sc., III., x., 17, 1875.

Occurrence in Hungarian trachytes, *Szabó*, J. Min., Beil.-Bd., i., 302, 1881.

Referred by *Mallard* (Ann. Min., VII., x., 100, 1876) to the triclinic system (pseudo-isometric). His conclusions are supported by *Bertrand* (Bull. Soc. Min., iv., 12, 13, 1881), who describes more fully the supposed method of grouping of the biaxial elements. For example, a dodecahedral crystal of aplome, according to this view, is made up of 48 biaxial crystals in the form of triangular pyramids meeting at the centre of the dodecahedron: the bases of four of these pyramids together form a dodecahedral plane. The acute negative bisectrix is sensibly normal to the base of the pyramid, and the plane of the axes sensibly parallel to the longer diameter of the rhombic face; the axial angle is about 90°. Bertrand adds that such a crystal can be mechanically divided into the 48 individuals corresponding to the optical division [but see also p. viii, analcite, p. 5, boracite, p. 17].

GARNIERITE, App. II., p. 23.—It has been shown that, as previously suggested, the substance called garnierite is not a definite mineral, but consists of a hydrous magnesian silicate more or less impregnated with nickel oxide; the amounts of magnesia and nickel vary widely. Some writers, however, prefer to regard the Ni as chemically replacing the Mg (in $RSiO_3 + n$ aq), but this seems very doubtful.—See *Ulrich*, Am. J. Sc., III., xi., 235, 1876; *Typke* found in two samples, 55·90 and 66·97 SiO_2, Ch. News, xxxiv., 193, 1876; *Garnier*, C. R., lxxxii., 1454, 1876; lxxxvi., 684, 1878; *Des Cloizeaux*, anal. by Damour, Bull. Soc. Min., i., 29, 1878; *vom Rath*, Ber. nied. Ges. Bonn, Jan. and July, 1878 (analyses by Ulrich and Kiepenheuer); *Liversidge*, Proc. Roy. Soc. N. S. W., Dec. 9, 1874, and Sept. 1, 1880. Liversidge calls the commonly occurring dark green unctuous mineral, *noumeaite*, and the rarer pale green adhesive mineral, *garnierite;* the latter he characterizes as a green-colored halloysite; in the former the NiO varies between 32·52 and 0·24 p. c., and the MgO between 10·61 and 24·82 p. c.

Similar deposits have been found in Spain, *Meissonier*, C. R., lxxxiii., 229, 1876.

Gastaldite.—See *Glaucophane*, p. 52.

Gay-Lussite, Min., p. 706.—According to Des Cloizeaux, the so-called pseudomorphs of calcium carbonate after gay-lussite, from Sangerhausen, have nothing to do with the latter mineral, but are probably pseudomorphs after celestite; Groth regards them as pseudomorphs after anhydrite (Min.-Samml. Strassburg, p. 142, 1878). Clarence King, however, describes large tufa-like deposits of calcium carbonate in Nevada, forming beds 20-60 feet thick, and at a height of 470 feet above the present level of Pyramid Lake. These deposits are regarded as the shore formation of an enormous lake, called Lake Lahontan, believed to have existed in quaternary times. This calcium carbonate shows occasionally crystalline forms resembling true gay-lussite, and the whole deposit is believed to have existed originally as this mineral. This view is supported by the fact that gay-lussite is now found well crystallized in a lake near Ragtown, Nevada, which is also a remnant of Lake Lahontan. For this pseudomorphous shore deposit King proposes the name of thinolite (from θίς, *shore*), Geology of the 40th Parallel, vol. i., 508, 1879.

Gay-lussite has been made artificially by *Favre* and *Soret*, Bull. Soc. Min., iv., 168, 1881. Crystallographic and optical examination of natural and artificial crystals, *Arzruni*, Z. Kryst., vi., 24, 1881.

Gedanite. *Otto Helm*, Arch. Pharm., III., xiii., 503, 1878 (Bull. Soc. Min., i., 133). A resin resembling amber, but not containing succinic acid, and less rich in oxygen. H. = 1·5–2. G. = 1·058–1·068. Color wine yellow, more or less clear. Transparent. Fragile. Fracture conchoidal. Analysis: C 81·01, H 11·41, O 7·33, S 0·25 = 100 (ash 0·06). Fuses to a clear odorless liquid at 180°, and sometimes at 140°. Found with amber on the shores of the Baltic. Named from *Gedanum*, Latin name of Danzig.

Gehlenite.—Min., p. 370; App. II., p. 23.

Genthite.—Min., p. 471; App. II., p. 24.

Geocronite, Min., p. 105.—**Anal.** (6 p. c. Cu), Björkskognäs, Sweden, *Nauckhoff*, Geol. För. Förh., i., 88, 1872.

Gersdorffite, Min., p. 72; App. II., p. 24.—**Anal.** (12·54 p. c. Co), Benahanis, prov. of Malaga, Spain, *Genth*, Am. Ch. J., i., 324, 1879.

An auriferous gersdorffite, from Rezbanya, Hungary, has been called sommarugaite (Bull. Soc. Min., i., 143).

Geyserite.—App. II., p. 24.

Gibbsite, Min., p. 177.—**Anal.**, French Guiana, *Jannettaz*, Bull. Soc. Min., i., 70, 1878.

Gieseckite.—Min., p. 479; App. II., p. 24.

. **Ginilsite.** (Fischer, Mitth.), *Rammelsberg*, Min. Chem., 2d ed., ii., 704; ZS. G. Ges., xxviii., 236, 1876.

Massive. Color grayish yellow. G. = 3·404. Analyses: 1, made in Rammelberg's laboratory; 2, Rammelsberg, ZS. G. Ges., xxviii., 236, 1876.

	SiO_2	Al_2O_3	Fe_2O_3	MgO	CaO	H_2O	
1.	38·75	4·83	16·32	9·48	26 52	3·73	= 99·63.
2.	37·83	7·77	15·63	9·73	26·67	3·30	= 100 93.

Formula $R_8[R_2]_2Si_7O_{28}$ + 2aq. This requires: SiO_2 37·10, Al_2O_3 7·85, Fe_2O_3 16·07, MgO 4·42, CaO 26·38, H_2O 3·18 = 100. Earlier analyses by Fellenberg and others, giving very different results, are discarded by Rammelsberg. B. B. fuses on the edges to a dark glass. From Ginilsalp, Graubünden, Switzerland. [Needs further examination.]

Gismondite, Min., p. 418; App. II., p. 24.—**Cryst.**, Salesel, Bohemia, *Seligmann*, Z. Kryst., i., 336, 1877. *Schrauf*, Z. Kryst., i., 596, 1877. Schlauroth, near Görlitz, *A. v. Lasaulx*, Z. Kryst., iv., 172, 1879. The crystalline system of gismondite was first given as tetragonal, afterward as orthorhombic. Later, Schrauf (l. c.) was led by the observed variations in angle to suggest that the crystals were twins, perhaps of triclinic individuals; von Lasaulx (l. c.) has carried on a more extended series of observations, both optical and crystallographic, and has established the truth of Schrauf's suggestion, showing the methods of twinning, and the way in which the pseudo-tetragonal forms result through it.

Giufite (or GIUFFITE).—See *Milarite*, p. 81.

GLANCESPAR.—App. II., p. 24.

GLASBACHITE.—App. II., p. 24.

GLAUCOPHANE, Min., p. 244.—Near amphibole in form and composition, from Zermatt, *Bodewig*, Pogg. Ann., clviii., 224, 1876. Syra, anal., *Lüdecke*, ZS. G. Ges., xxviii., 248, 1876. With garnet and mica from Balade mine, Ouegoa, New Caledonia, anal., *Liversidge*, Proc. R. Soc. N. S. W., Sept. 1, 1880. Discussion of composition, *Dölter*, Z. Kryst., iv., 38, 1879. Analyses: 1, Bodewig (l. c.); 2, Lüdecke (l. c.); 3, Liversidge (l. c.).

		SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	Na_2O
1. Zermatt, G. = 3·091	$(\frac{2}{2})$	57·81	12·03	2·17	5·78	....	13·07	2·20	7·33 = 100·45.
2. Syra,		55·64	15·11	3·08	6·85	0·56	7·80	2·40	9·34 = 100·78.
3. New Caledonia, G. = 3·12	$(\frac{2}{2})$	52·79	14·44	....	9·82	tr.	11·02	4·29	5·26, K_2O 0·88, H_2O 1·38 = [illegible]

A mineral closely related to glaucophane, is called GASTALDITE by *G. Strüver*, Mem. Accad. Lincei, II., ii., 333, 1875. Description as follows:

Monoclinic. In prismatic crystals with *I* and *i-ī*, but not distinctly terminated. In fibrous or columnar masses. Cleavage prismatic, 124° 25′ (like amphibole). H. = 6-7. G. = 3·044. Lustre vitreous to pearly. Color azure blue to blackish blue. Streak grayish blue. Fracture conchoidal. Optic-axial plane clinodiagonal. Double refraction negative. Dispersion inclined; strongly pleochroic.

Composition: $3RSiO_3 + 2[Al_2]Si_3O_9$, with R = Fe, Mg, Ca, Na_2. Analysis, Cossa:

	SiO_2	Al_2O_3	FeO	MgO	CaO	Na_2O	K_2O	
$(\frac{2}{2})$	58·55	21·40	9·04	3·92	2·03	4·77	tr.	= 99·71.

Occurs in the western Alps in chlorite slate in the valley of Aosta, at Brosso, near Ivrea, and in the valley of Locana, Italy, accompanied by pyrite, chalcopyrite, garnet, and apatite. Named after Prof. Bartolomeo Gastaldi.

GLAUCOPYRITE.—App. I., p. 6.

Guadalcazarite.—See *Onofrite*, p. 86, and App. II., p. 25.

Guanajuatite, App. II., p. 22.—The sulphoselenide of bismuth, from Guanajuato, Mexico, first mentioned by Castillo (1873), and fully described by Frenzel (J. Min., 1874, 679), was called *Frenzelite* in Append. II. (q. v.). It appears, however, that the same mineral was described in 1873 by V. Fernandez, and named *Guanajuatite* (La República: Periódico oficial del Gobierno del Estado de Guanajuato, July 13); the latter name has, consequently, the priority. Fernandez concludes that the mineral contains only Bi_2S_3, the sulphur being due, in his opinion, to pyrite. He obtained: Se 35·18, Bi 61·00, gangue 3·70, Fe, S, loss 0·12 = 100. He also gives, H. = 3·5, G. = 6·62; the locality is the Santa Catarina mine, Sierra de Santa Rosa, near Guanajuato. The same mineral is called castillite by Domeyko, Min. Chili, 3d ed., p. 310, 1879.

Mallet has re-examined the mineral, and obtained (Am. J. Sc., III., xv., 294, 1878):

Se	S	Bi	Al_2O_3	Fe_2O_3	SiO_2	H_2O	
31·64	0·61	59·92	2·53	tr.	3·47	1·46	= 99·63.

After deducting 6·72 p. c. halloysite, and 0·56 SiO_2, present as impurities, the result obtained is: Se 34·33, S 0·66, Bi 65·01 = 100. The formula is then Bi_2Se_3, with a little of the selenium replaced by sulphur; the pure mineral contains no zinc.

The **silaonite** of *V. Fernandez* and *S. Navia* (La República, Guanajuato, Mexico, Dec. 25, 1873), is a massive, bluish-gray mineral. H. = 2·75. G. = 6·43–6·45. Described as having the composition Bi_3Se. Shown subsequently by Fernandez, and also by H. D. Bruns (Chem. News, xxxviii., 109, 1878), to be a mixture of guanajuatite and native bismuth, and not a homogeneous mineral.

Guano, App. I., p. 6.—Domeyko (C. R., xc., 544, 1880), gives the following analyses of minerals occurring in the guano of Mejillones. (1) Of imperfect crystals in the form of rectangular prisms, implanted on walls of natural fractures in the rock; colorless, with vitreous lustre. (2) Fibrous and in very elongated crystals, pyramidal in form, grouped in diverging bundles; grayish, lustre vitreous. (3) In small concretions in the earthy mass of the guano; soft on exterior, within compact and homogeneous; amorphous; color yellowish.

	P_2O_5	MgO	CaO	H_2O (and organic matter).	
1.	64·89	35 11 = 100.			
2.	40·13	18·53	5·80	36·00 = 100·46.	
3.	27·60	24·38	0·14	38·30	B_2O_3 6·80 (Al_2O_3) Fe_2O_3 2·30 = 99·52.

Guanipite.—See *Oxammite*, p. 88.

GUANOVULITE.—App. II., p. 64.

GUARINITE, Min., p. 383; App. II., p. 26.—**Cryst.**, *Guiscardi*, Rend. Acc. Nap., Jan., 1876.

Guejarite. *Cumenge*, Bull. Soc. Min., ii., 201, 1879; *Friedel*, ib., ii., 203.

Orthorhombic; in prismatic (20 mm. long) crystals flattened parallel to the brachypinacoid, with the planes $i\text{-}\breve{2}$, $i\text{-}\breve{\tfrac{3}{2}}$, $i\text{-}\breve{\tfrac{5}{2}}$ in the prismatic zone, also $1\text{-}\breve{\imath}$ and $\tfrac{1}{3}\text{-}\breve{\imath}$, and several others less certain. $I \wedge I = 101° 9'$, $i\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath} = 128° 6'$. Cleavage $i\text{-}\breve{\imath}$ neatly perfect (Friedel). H. = 3·5. G. = 5·03. Color steel gray, with a tinge of blue. Analysis, Cumenge (l. c.):

S	Sb	Cu	Fe	Pb
25·0	58·5	15·5	0·5	tr. = 99·5.

The calculated formula is $Cu_2Sb_4S_7$, or $Cu_2S + 2Sb_2S_3$. Related to chalcostibite (Min., p. 85), the formula for which is $Cu_2S + Sb_2S_3$, and which has $I \wedge I = 101°$. B. B. on charcoal gives off antimonial fumes, and yields when treated with soda metallic copper. Occurs with siderite at the copper mines at the foot of Muley-Haceu, in the district of Guejar, Sierra Nevada, Andalusia.

GÜMBELITE, App. I., p. 6.—*Gümbel* (Min. Petr. Mitth., ii., 189, 1879), has analyzed a mineral occurring as the petrifying material of coal plants in the Tarentaise, with the following results: SiO_2 49·71, TiO_2 1·04, Al_2O_3 28·62, Fe_2O_3 2·69, MnO tr., MgO 1·60, CaO tr., K_2O 6·80, Na_2O 2·21, H_2O 7·38 (and coal) = 100·05. It occurs in fine white pearly scales, somewhat greasy to the feel. G. = 2·8. Exfoliates like pyrophyllite. These results show that the mineral is essentially the same as that called gümbelite by von Kobell, or a sort of pinite. *Genth* (Am. Phil. Soc. Philad., xviii., 259, 1879), describes a mineral occurring in a similar manner to the above in coal shales, and as a petrifying material; but it is a true pyrophyllite.

GUMMITE, Min., p. 179.—Occurrence at the Flat Rock mine, Mitchell Co., N. C., *Kerr*, Am. J. Sc., III., xiv., 496, 1877; *Hidden*, ib., xxii., 22, 1881. *Genth* (Am. Chem. J., i., 89, 1879), has analyzed this gummite from North Carolina, and concludes that it is a mechanical mixture of uranium hydrate, uranotil, lead uranate, and barium uranate.

GYPSUM, Min., p. 637; App II., p. 26.—**Cryst.**, *Laspeyres*, Min. Mitth., 1875, 113 (*Reusch*, ib., 1876, 67). *Klien*, Pogg. Ann., clvii., 611, 1876.

Elasticity in different directions, *Coromilas*, Z. Kryst., i., 407, 1877. Magnitude and position of optical axes of elasticity, *von Lang*, Ber. Ak. Wien, lxxvi., 793, 1877. Etching figures, *Weiss*, ZS. G. Ges., xxix., 211, 1877. Thermo-electrical properties, *Hankel*, Wied. Ann., i., 277, 1877. Influence of heat on double refraction, *Dufet*, Bull. Soc. Min., iv., 113, 191, 1881.

Occurrence at Vesuvius, *Scacchi*, Att. Acc. Napoli, vi. (Contr. Min., ii., 57).

GYROLITE, Min., p. 398. See *Tobermorite*, p. 123.

Haddamite.—See *Microlite*, p. 80.

HALITE, Min., p. 112.—Vesuvius, *Scacchi*, Att. Acc. Nap., vi., 1873 (Contr. Min., ii., 23). Elasticity in different directions determined, *Voigt*, Pogg. Ann., Erg.-Bd., vii., 1, 177, 1875; *Groth*, Pogg. Ann., clvii., 115, 1876.

Figures produced by etching, *Sohncke*, Pogg. Ann., clvii., 329, 1876; *Exner*, ib., clviii., 319, 1876.

An argentiferous variety of halite is called HUANTAJAYITE by *Raimondi* (in Domeyko, 5th Appendix Min. Chili, 1876; also Min. Pérou, p. 64, 1878).

Isometric; occurs in cubes, also in incrustations made up of minute cubic crystals, also fibrous. H. = 2. Color white, not altered by exposure. Transparent. Fragile not sectile like cerargyrite. Composition: 20NaCl + AgCl; an analysis (¾) gave: NaCl 89, AgCl 11 = 100. B. B. decrepitates and fuses easily; on charcoal yields silver with soda. Occurs in a calcareous gangue with cerargyrite, embolite, etc., at the mine of San Simon, Huantajaya, Tarapaca, Peru. Called *lechedor* by the miners. First described by Raimondi in the Annales de la Société de Pharmacie de Lima, 1873. See also Domeyko, Ann. Min., VII., xix., 329, 1881.

HALLITE.—App. II., p. 26.

HALLOYSITE, Min., p. 475; App. II., p. 26.—**Anal.**, Steinbrück, *Gamper*, Verh. G. Reichs., 1876, 354. Tüffer, Styria, *John*, Jahrb. G. Reichs., 1878, 386. Drenkova, Banat, *Helmhacker*, Min. Petr. Mitth., ii., 231, 1879. Distr. San Mateo, Peru, *Raimondi*, Min. Pérou, p. 304, 1878.

A white porcelain clay, valuable in the arts, from Lawrence Co., Indiana, is called INDIANAITE by *Cox* (Rep. Geol. Indiana, 1874, 15; 1878, 154). It occurs with allophane in beds four to ten feet thick. H. = 2–2·5. G. = 2·31–2·53. Analyses, 1, 2, 3, by Pemberton:

SiO_2	Al_2O_3	H_2O	H_2O at 100° C.	CaO, MgO	Alkalies.
39·00	36·00	14·00	9·50	0·63	0·54 = 99·67.
39·35	36·35	22·90		0·40	.... = 99·00.
38·90	37·40	23·60		undet.	.... = 99·90.

HALOTRICHITE, Min., p. 654.—**Anal.**, Idria, *v. Zepharovich*, Ber. Ak. Wien, lxxxix., 183, 1879.

HAMARTITE.—See *Bastnäsite*, App. I., p. 2 and 7; also *Tysonite* in this App., p. 126.

Hannayite. *vom Rath*, Ber. nied. Ges. Bonn, Jan. 13, 1878; Bull. Soc. Min., ii., 79, 1879.

Triclinic; in prismatic crystals, $I \wedge I' = 114° 34'$, $I \wedge i\text{-}\breve{i} = 140° 28'$. Cleavage basal perfect, less so, parallel *I* and *I'*. Prismatic planes vertically striated. G. = 1·893. Analysis by MacIvor:

	P_2O_5	MgO	H_3N	H_2O
(½)	45·70	18·90	8·09	28·20 = 100·89.

Heated 36 hours at 100° undergoes no change; between 100° and 110° or 115° loses 21·08 p. c., becoming opaque; heated over a Bunsen flame loses the remainder of the water and the ammonia (36·48 = total loss). The remainder fuses, but dissolves only in part in concentrated HCl. Taking the loss between 100° and 120° as water of crystallization, the formula is $H_4(NH_4)Mg_3P_4O_{16} + 8aq$, which requires: P_2O_5 44·38, MgO 18·75, H_3N 8·75, H_2O 28·12 = 100.

Discovered by MacIvor of Melbourne in the guano of the Skipton caves, Victoria, and recognized as new by Ulrich, as stated in a letter to vom Rath; occurs with struvite and newberyite. Named after Prof. J. B. Hannay, of Manchester.

HARMOTOME, Min., p. 439; App. II., p. 26.—*Mallard* (Ann. Min., VII., x, 153, 1876), following Des Cloizeaux, classes harmotome among pseudo-orthorhombic species, and calls attention to its relation in form to analcite and also phillipsite. *Baumhauer* (Z. Kryst., ii., 113, 1878) describes the results of a careful optical examination, and doubts the correctness of referring it to the monoclinic system, but *Fresenius* (ib., iii., 42) supports the conclusion of Des Cloizeaux.

HATCHETTITE, Min., p. 731; App. II., p. 26. Monte Falo, near Savigno, Italy, *Casali, Bombicci*, Mem. Ac. Bologna, III., viii., 1877 (Z. Kryst., ii., 506).

Hatchettolite. *J. L. Smith*, Am. J. Sci., III., xiii., 365, May, 1877. *O. D. Allen*, ibid., xiv., 128, Aug., 1877.

Isometric; in octahedrons with planes of the cube, and 3-3. H. = 5. G. = 4·77–4·90. Lustre resinous. Color yellowish brown. Translucent. Fracture subconchoidal.

Analyses: 1, 2, 3, Smith (l. c.); 4, 5, Allen (l. c.):

	Ta_2O_5	Cb_2O_5	TiO_2	WO_3	SnO_2	UO_3	CaO	Y_2O_3*	FeO	MgO	K_2O	Na_2O	H_2O
1.	66·01		....	0·75		15·20	7·72	2·00	2·08	....	0·50	....	5·16 Pb tr. = 99·42, Smith.
2.	67·86		....	0·60		15·63	7·09	0·86	2·51	....	1·21	....	4·42 = 100·18, Smith.
3.	67·25		....	0·91		16·01	7·11	0·64	2·12	....	undet.	....	5·02 = 99·06, Smith.
4.	29·83	34·24	1·61	0·30		15·50	8·87	....	2·19	0·15	tr.	1·37	4·49 Pb tr. = 98·55, Allen.
5.	29·60	35·94		....		....	8·89	....	2·33	....	....	....	.... Allen.

* With cerium oxide.

From analysis 4 Allen deduces the formula $\overset{\text{i}}{R}_2\overset{\text{v}}{R}_2O_7 + 2\overset{\text{ii}}{R}\overset{\text{v}}{R}_2O_6 + 4aq$, with $R = UO_2$, Ca, Fe, Mg, Na_2, and $\overset{\text{v}}{R}$ = Ta, Cb. Allen calls attention to the close relation to pyrochlore, and suggests that the original mineral in this case may have been anhydrous and hence analogous to it in composition. The pyrognostic characters are near those of pyrochlore.

Occurs with samarskite, sometimes implanted on the former mineral, in the mica mines of Mitchell Co., North Carolina. Named after the English chemist Hatchett.

Haughtonite.—See *Mica Group*, p. 77.

HAÜYNITE, Min., p. 332; App. II., p. 26.—Cryst., Albani Mts., *Strüver*, Z. Kryst., i., 235, 1877.

HAYESINE, Min., p. 599.—Anal., Atacama, Chili, *Domeyko*, Ann. Min., VII., x., 26, 1876.

HEDYPHANE, Min., p. 537.—Långban, Sweden, *Lindström* (Geol. För. Förh., iv., 266, 1879). G. = 5·82. Color white or yellowish white. Analysis after deducting a little $CaCO_3$: As_2O_5 29·01, P_2O_5 0·55, PbO 41·01, BaO 8·27, CaO 7·85, MgO 0·25, Pb 9·17, Cl 3·14, Fe_2O_3 0·08, Na_2O 0·15, K_2O 0·09 = 99·57; this corresponds to the usual formula $3R_3As_2O_8 + PbCl_2$, but the variety is remarkable as containing so much barium. The hedyphane of Paisberg contains no barium or at most only a trace.

According to *Des Cloizeaux* (Bull. Soc. Min., iv., 93, 1881), the Långban hedyphane is monoclinic and perhaps isomorphous with caryinite, p. 20.

See also *Mimetite*, p. 81.

HEBRONITE.—See *Amblygonite*, p. 5.

Heldburgite. *Luedecke*, Zeitsch. gesammt. Nat., III., iv., 291, 384, 1879.

Tetragonal, *c* (vert.) = 0·7500. In minute (3 mm. long, $\frac{1}{4}$ to $\frac{1}{2}$ mm. thick), prismatic crystals. Planes *i-i*, *I*, 1; angle $I \wedge 1 = 136° 41'$ (near zircon). In habit resembles guarinite. H. less than that of steel. Lustre adamantine. Color yellow. Streak white. Transparent. B. B. infusible. Composition unknown (TiO_2 absent). Occurs in the feldspar of the phonolyte of the Heldburg near Coburg. [Needs further examination.]

HELVITE, Min., 264; App. II., p. 27.

HEMATITE, Min., p. 140; App. II., p. 27.—Cryst., Vesuvius, *Scacchi*, Att. Accad. Napoli, vi., 1873 (Contr. Min., ii., 1). *Sadebeck*, Pogg. Ann., clvi., 557. Binnenthal, *Bücking*, Z. Kryst., i., 562; ii. 416. *Groth*, Min.-Samml. Strassburg, p. 78, 1878. Biancaville, Etna, *v. Lasaulx*, Z. Kryst., iii., 294, 1879. Reichenstein, Silesia, *Hare*, Z. Kryst., iv., 297, 1879. Ascension Island, *vom Rath*, Z. Kryst., vi., 192, 1881.

Crystallogenetic observations, *Scharff*, Jahresb. Senck. Nat. Ges., 1879–80.
With magnoferrite, octahedral crystals, Vesuvius, *vom Rath*, J. Min., 1876, 386. With magnetite in parallel position, *Bücking*, Z. Kryst., i., 575; do. with marcasite, *Sadebeck*, Pogg. Ann. Erg.-Bd., viii., 625

HENRYITE.—App. II., p. 27.

Henwoodite. *J. H. Collins*, Min. Mag., i., 11, 1876; *C. Le Neve Foster*, ibid., p. 8.
In botryoidal globular masses having a crystalline structure. H. = 4–4·5. G. = 2·67. Color turquoise blue. Streak white with bluish green tinge. Fracture conchoidal. Analyses, Collins (l. c.):

	P_2O_5	Al_2O_3	Fe_2O_3	CuO	CaO	H_2O	SiO_2	
1.	48·94	18·24	2·74	7·10	0·54	17·10	1·37	Loss 3·97 = 100.
2.	48·20	....	....	7·00	....	19·50	....	

The iron, lime, and silica are regarded as due to impurities; but aside from this the analyses are so obviously imperfect, that it is useless to attempt to give a formula; the mineral, however, seems to be related most closely to turquoise. In the closed tube decrepitates slightly, gives off water, and turns brown. B. B. infusible, colors the flame green. Copper reactions with borax. Occurs on limonite at the West Phenix mine, Cornwall. Named from Mr. Wm. Jory Henwood.

Hermannolite. See *Columbite*, p. 29.

Herrengrundite. *Brezina*, Z. Kryst., iii., 359, March 25, 1879. URVÖLGYITE. *Szabó*, Min. Mitth., ii., 311, 1879 (Lit. Ber. Ungarn, iii., 510, 1879).
Monoclinic (triclinic?) : c (vert.) : b : $\breve{a}$ = 2·8004 : 1 : 1·8161. $\beta = 91°\ 9'$. Observed planes: O, $-\frac{1}{2}\text{-}i$, $-\frac{4}{7}\text{-}i$, $\frac{1}{2}\text{-}i$, $\frac{4}{7}\text{-}i$, 1, I, $i\text{-}\frac{9}{8}$, i-$\frac{1}{4}$, $i\text{-}\breve{\frac{1}{4}}$, $i\text{-}\breve{\frac{4}{3}}$, $i\text{-}\breve{2}$, $i\text{-}\breve{\frac{1}{2}}$. $I \wedge I = 57°\ 42'$, $O \wedge 1 = 106°\ 52'$, $O \wedge I = 90°\ 34'$. Cleavage basal perfect. I less so, also i-2 or $i\text{-}\breve{2}$ (?). Occurs in spherical groups of thin six-sided plates. The basal plane striated parallel i-i. Twinning plane generally O. Optic axes in plane parallel to the direction of striation. $2E_a = 59°\ 2'$ (Li), 65° 18′ to 66° 53′ (Na), 68° 39′ (Tl). Double refraction negative. (Brezina.) Dichroism weak, bluish green and greenish yellow. H. = 2·5. G. = 3·132. (Winkler.) Lustre vitreous, on cleavage face sometimes pearly. Color emerald green, verdigris green, and bluish green. Streak light green. Transparent. Analyses; 1, Berwerth, Z. Kryst., iii., 373; 2, Schenek, Min. Mitth., ii., 315, 1879.

	SO_3	CuO	CaO	H_2O
1.	24·62	54·16	2·05	19·61 = 100.
2.	24·62	49·52	8·59	16·73, S_2O_3 0·33, FeO 0·14, MnO, MgO tr. = 99·93.

Brezina regards the CaO as present in the form of gypsum as an impurity; deducting this the result obtained is: SO_3 23·04, CuO 57·52, H_2O 19·44 = 100. Szabó, on the contrary, regards the CaO as essential, and writes the formula: $(CuSO_4 + aq) + 3H_2CuO_2 + (CaSO_4 + 2aq)$. [The view of Szabó seems very improbable, and is not established by his experiments made to decide the point; the mineral needs further examination on the chemical side.]
Occurs with malachite and calcite in a quartz conglomerate at Herrengrund in Hungary. Related to langite, brochantite, etc. Named from the locality Herrengrund = Urvölgy in Hungarian.

HERSCHELITE, Min., p. 437; App. II., p. 27.—The herschelite of Richmond, Victoria (called seebachite by Bauer, App. II., p. 50), is referred to phacolite (chabazite) by *vom Rath* (Ber. Ak. Berlin, 1875, 523); Becke, however, shows (Min. Petr. Mitth., ii., 416, 1879), that it differs from chabazite; he regards the form as monoclinic united by twinning in a manner analogous to, but not identical with, chabazite. A similar result is reached by *von Lasaulx* (Z. Kryst., v., 338, 1881) for the herschelite from Aci Castello, Sicily; an analysis yielded: SiO_2 47·15, Al_2O_3 21·42 (with Fe_2O_3), CaO 5·34 (with MgO), Na_2O, K_2O [6·69], H_2O 19·40 = 100, leading to the formula $(Na, K)_2\,Ca\,[Al_2]_2Si_8O_{24} + 12aq$.

HESSITE, Min., p. 50; App. II., p. 27.—*Schrauf* (Z. Kryst., ii., 242, 1878), describes a highly modified crystal from Rezbanya; he refers it to the isometric system, and shows that the species is isomorphous with argentite, he notes, however, the variations in the measured angles, but concludes that they fall within the probable errors of observation. *Krenner* (Z. Kryst., iv., 542), describes isometric crystals of unusual perfection from the Jacob and Anna mine, Botes Mt., between Zalathna and Vöröspatak, Transylvania. *Becke* (Min. Petr. Mitth., iii., 301, 1880) has subjected the crystals from Botes to a careful examination, and argues [but not conclusively] that they must be referred to the triclinic system, although they closely approximate to the isometric form. An analysis gave him: Ag 60·69, Au 1·37, Te 37·22, quartz 0·40 = 99·68, corresponding to Ag_2Te with, as assumed by the author, a little Au_2Te_3.

From Kearsarge mine, Dry Cañon, Utah, *Genth* (anal. by *Raht*), Am. Phil. Soc. Philad., xvii., 115, 1877 (or Z. Kryst., ii., 3). Chili, *Domeyko*, C. R., lxxxi., 632, 1875.

Hetærolite. *G. E. Moore*, Am. J. Sc., III., xiv., 423, Nov., 1877. HETAIRITE, Naumann-Zirkel, Min., 11 ed., p. 371.

Announced as follows, but not fully described: In botryoidal coatings with columnar radiate structure. H. = 5. G. = 4·933. Lustre metallic to submetallic. Color black. Streak brownish black. Opaque. Brittle. Contains zinc and manganese, and stated to be a zinc hausmannite, but no analyses published. Occurs intimately associated with chalcophanite (whence name from ἑταῖρος, *companion*) at the Passaic zinc mine, Sterling Hill, New Jersey. [A more complete description is needed.]

HETAIRITE.—See *Hetærolite.*

HETEROGENITE, App. II., p. 27.—St. Anton mine, Heubach, near Wittichen, Baden, *Sandberger*, J. Min., 1876, 280.

HETEROMORPHITE.—See *Jamesonite*, p. 64.

Heubachite. *F. Sandberger*, Ber. Ak. München, 1876, 238.

In thin soot-like incrustations; in dendritic or small spherical aggregates. H. = 2·5. G. = 3·44. Color deep black. Streak submetallic. Analysis, Zeitschel (l. c.):

Co_2O_3	Ni_2O_3	Fe_2O_3	Mn_2O_3	H_2O
65·50	14·50	5·13	1·50	12·59 = 99·22.

This corresponds to $3R_2O_3 + 4H_2O$. B. B. infusible. Soluble in concentrated hydrochloric acid, with evolution of chlorine; the solution deep bluish green, but on dilution with water becomes rose red. Occurs as a secondary product coating barite at the St. Anton mine, in the Heubachthal, near Wittichen, Baden; also at the mine Eberhard, near Alpirsbach, Würtemberg. This mineral was first referred to heterogenite by Sandberger, J. Min., 1876, 280. [Is the substance homogeneous ?]

HEULANDITE, Min., p. 444; App. II., p. 28.—Cryst., Turkestan, *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xiii., 389 (Z. Kryst., ii., 503).

Anal., Orange Free State, So. Africa, *Cohen*, J. Min., 1875, 116. San Piero, Elba, *Grattarola* and *Sansoni*, Att. Acc. Tosc., iv., 175, 1879; ib., p. 314.

Occurs at Leiperville, Delaware Co., Penn., *König*, Z. Kryst., ii., 303, 1878.

See also *Epistilbite*, p. 42; and *Oryzite*, p. 87.

Hexagonite.—See *Amphibole*, p. 5.

Hibbertite. *Heddle*, Min. Mag., ii., 24, 1878.

Pulverulent. Color lemon yellow. Analysis after deducting 20·68 p. c. of the matrix, kammererite, insoluble in dilute acid: CO_2 25·44, FeO 3·23, MnO 0·58, MgO 26·56, CaO 28·46, H_2O 15·73 = 100. From a quarry of chromite on the island of Unst. Named after Mr. Hibbert, the discoverer of the chromite. [The investigation of the substance is not sufficiently complete to prove that it is a distinct species; it seem to be a mixture allied to predazzite and pencatite, Min., p. 708, 709; and App. II., p. 45.]

Hiddenite.—See *Spodumene*, p. 112.

Hisingerite, Min., p. 489; App. II., p. 28.—Anal. of a related mineral (Collins), Japan, *Milne*, Min. Mag., iii., 99, 1879.

Hofmannite. *Bechi*, Acc. Linc. Trans., III., ii., 185, 1878. Occurs in tabular crystals, shaped like rhombs; they are colorless, tasteless, and odorless. G. = 1·0565. Soluble in alcohol (5 pts. in 1000 pts. alcohol at 14°) more readily than in ether. Melts at 71° to a fluid resembling olive oil, burns with a bright flame. Composition $C_{20}H_{36}O$; an analysis gave: C 82·23, H 12·20, O 5·57. Forms a white crystalline efflorescence on lignite in the neighborhood of Siena. Named after Prof. A. W. Hofmann, of Berlin.

Homilite. *S. R. Paijkull*, Geol. För. Förh., iii., 229, 1876. *Des Cloizeaux* and *Damour*, ib., iii., 385, 1877, or Ann. Chim. Phys., V., xii., 405, 1877.

Monoclinic. In angles closely related to gadolinite and datolite. $I \wedge I = 116^\circ$, $O \wedge i\text{-}i = 90^\circ\ 39'$, $O \wedge 2\text{-}i = 147^\circ\ 20'$ (O, I, $2\text{-}i = i\text{-}i$, $2\text{-}i$, I of datolite, Min., p. 380). Crystals octahedral in habit by extension of I and $2\text{-}i$, also O and $i\text{-}i$ prominent. Cleavage indistinct. Axes in a plane perpendicular to plane of symmetry, bisectrix nearly parallel to prismatic edge. $2H_a = 97^\circ\ 5'$ to $98^\circ\ 22'$ (red). Dispersion $\rho > \upsilon$, also of bisectrices horizontal (Des Cloizeaux). H. = 4·5–5 (5·5 Paijkull). G. = 3·34 (3·28 Paijkull). Lustre resinous to vitreous. Color black or blackish brown. Streak grayish. Translucent in thin splinters. Analyses: 1, Paijkull (l. c.); 2, Damour (l. c.);

	SiO_2	B_2O_3	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	Ce_2O_3*	Na_2O	K_2O	ign.
1.	31·87	[18·08]	1·50	2·15	16·25	....	0·52	27·28	....	1·09	0·41	0·85 = 100.
2.	33·00	[15·21]	....	....	18·18	0·74	....	27·00	2·56	1·01	....	2·30 = 100.

* With La_2O_3, Di_2O_3.

From analysis 1 the following formula is calculated: $FeCa_2B_2Si_2O_{10}$, which corresponds closely with that of datolite, to which the mineral is similar in crystalline form. This similarity was first pointed out by Nordenskiöld (Geol. För. Förh., iii., 232, 1876). B. B. homilite fuses very readily to a black glass; reacts for iron and boracic acid. Completely decomposed by HCl with gelatinization. Found on the Stockö near Brevig, Norway, with meliphanite and erdmannite. Named from ὁμιλέω, *to occur together*.

Des Cloizeaux remarks that some crystals of homilite are throughout doubly refracting, others are composed of a green doubly refracting kernel surrounded by a yellowish crust of singly refracting material, while still others are entirely singly refracting. In this respect it is closely similar to gadolinite; whether this variation is certainly due to alteration does not appear. An analysis of some of the isotropic, brownish-colored fragments gave Damour (G. = 3·03): SiO_2 28·01, B_2O_3 5·54, ZrO_2 3·47, Al_2O_3 3·31, CeO 19·28, DiO,LaO 8·09, FeO 5·43, MnO 1·35, CaO 11·00, K_2O 1·98, SnO_2 0·45, H_2O 12·10, TiO_2 tr. = 100. Damour remarks the similarity in appearance of the isotropic mineral analyzed by him to true erdmannite, and adds that the mineral supposed to be the latter contains no boron (see also p. 43).

Hopeite, Min., p. 514.—*Damour* and *Des Cloizeaux*, Bull. Soc. Min., ii., 131, 1879. *Friedel* and *Sarasin*, ib., p. 153.

Des Cloizeaux has made a crystallographic and optical examination of hopeite, confirming and extending the results of Lévy and Haidinger. Damour shows that it is essentially a zinc phosphate, and Friedel and Sarasin have succeeded in forming artificially crystals which have the form and optical properties of hopeite, and which have the composition $Zn_3P_2O_8 + 4aq$, which requires: P_2O_5 31·07, ZnO 53·18, H_2O 15·75. They conclude that this formula expresses also the composition of natural hopeite. According to Schrauf his new species eggonite (q. v.) is closely related in form to hopeite.

Horbachite.—App. II., p. 28.

Hornblende.—See *Amphibole*, p. 5.

Hortonolite.—App. I., p. 7.

Howlite.—Min., p. 598; App. II., p. 28.

Huantajayite.—See *Halite*, p. 55.

HUASCOLITE, Min., p. 42.—A massive mineral having a bluish gray color is referred to huascolite by *Raimondi* (Min. Pérou, p. 202, 1878). He obtained after deducting 14·50 p. c. gangue: S 27·76, Pb 26·86, Zn 44·50, Fe 0·88 = 100, from the Poderosa mine, Province of Dos de Mayo, Peru. *Domeyko* describes a mineral from Morochocha, Peru, corresponding in composition to PbS + (Zn, Fe) S, with Zn = 16·59; another from Coro-Coro, Bolivia, afforded 5 p. c. ZnS (6th App. Min. Chili, p. 17, 1878).

HÜBNERITE, Min., p. 603; App. II., p. 28.—Nevada, containing thallium, *Sandberger*, J. Min., 1877, 508. From Morochocha, Peru, *Raimondi*, Min. Pérou, p. 241, 1878. Occurs at Rabenstein, *Sandberger*, J. Min., 1879, 369. Found by W. P. Jenney, in the Black Hills, Dakota, at the Comstock mine, near Deadwood.

Hullite. *E. T. Hardman*, Proc. Roy. Ir. Acad., II., iii., 161, 1878.
Massive. H. = 2. Color velvet black. Lustre waxy but dull. Analysis, Hardman: SiO_2 39·44, Al_2O_3 10·35, Fe_2O_3 20·72, FeO 3·70, MgO 7·47, CaO 4·48, H_2O 13·62, MnO tr., CO_2 tr. = 99·78. Occurs filling and coating vesicular cavities in the basalt of Carnmoney Hill, near Belfast, Ireland.

Heddle remarks that hullite may be considered as a desiccated chlorophæite, but he also gives the following analysis of a similar mineral from the basalt at Kinkell, in Fifeshire, Scotland: SiO_2 38·59, Al_2O_3 17·34, Fe_2O_3 (FeO undet.) 15·97, MnO 1·56, CaO 3·94, MgO 8·65, K_2O 0·67, H_2O 13·48 (at 100° 8·04) = 100·20. This he regards as a homogeneous mineral, and believes it to somewhat support the claim of hullite to be considered as an independent species, Trans. Roy. Soc. Edinb., xxix., 89, 1879. [Near delessite; compare also diabantite.]

Huminite. A hydrocarbon from Östmark, in Wermland, Sweden, which, according to Ekman (Œfv. Ak. Stockh., 1868, 138), has the composition (ash free): C 67·15, O 29·83, H 2·55, N 0·47, S [0·40] = 100. A similar coal from Gryhytte, Finberget, Sweden, has, according to Helland (Geol. För. Förh., ii., 521, 1875), the composition (ash free): C 67·67 O 28·11, H 3·89, N tr., S 0·33 = 100.

HUMITE, Min., p. 363.—See *Chondrodite*, p. 26; and App. II., p. 28.

Huntilite.—See *Macfarlanite*, p. 71.

HYALITE.—Min., p. 199; App. II., p. 28.

HYALOSIDERITE.—Min., p. 256; App. II., p. 28.

Hyalotekite. *Nordenskiöld*, Geol. För. Förh., iii., 382, 1877.
Massive. Coarsely crystalline. Cleavage easy in two directions, at an angle of approximately 90°; also less easy in a third direction, in the same zone (Des Cloizeaux). H. = 5–5·5. G. = 3·81. Lustre vitreous to greasy. Color white to pearly gray. Transparent in very thin plates. Brittle. Optically biaxial, axes in a plane parallel to the axis of the zone of three cleavages: 2H = 98°–99° (red), bisectrix positive (Des Cloizeaux, Bull. Soc. Min., i., 9, 1878). An incomplete analysis gave:

SiO_2	PbO	BaO	CaO	ign.	
39·62	25·30	20·66	7·00	0·82	Al_2O_3, K_2O, etc., tr.

B. B. fuses to a clear glass, which in R. F. becomes blackened with reduced lead. On charcoal with soda in small amount fuses to a clear glass; with more soda in R. F. gives a lead globule and a coating of lead oxide. In salt of phosphorus dissolves, leaving a skeleton of silica. Insoluble in hydrochloric or sulphuric acids. Occurs sparingly in a grayish-white feldspar, with hedyphane and schefferite, at Långban, Wermland, Sweden. Named from ὕαλος, *glass*, and τήκειν, *to melt*.

HYDRARGILLITE.—See *Gibbsite*, p. 51

Hydrargyrite.—App. II., p. 28 (8).

Hydrocastorite.—See *Petalite*, p. 91.

Hydrocerussite. *Nordenskiöld*, Geol. För. Förh., iii., 381, 1877.
A hydrous lead carbonate (perhaps $2PbCO_3 + H_2O$), occurring sparingly as a coating on native lead, at Långban, Wermland, Sweden. It consists of white, colorless, crystalline plates, showing one perfect cleavage; soft. Soluble in acid with evolution of carbon dioxide. According to Bertrand (Bull. Soc. Min., iv., 87, 1881), the mineral occurs in hexagonal plates, and optically is uniaxial, negative. [Needs further examination.]

Hydrocuprite.—App. II., p. 28.

Hydrocyanite.—App. II., p. 29.

Hydrofluorite. *Scacchi*, Att. Acc. Napoli, vi., 1873 (Contrib. Min., ii., 65). Hydrofluoric acid gas observed at Vesuvius, especially after the eruptions of 1870 and 1872.

Hydrofranklinite. According to the late *W. T. Rœpper*, a new hydrous oxide of zinc, manganese, and iron. Occurs in small, very brilliant iron-black regular octahedrons; with octahedral cleavage highly perfect. H. = 4–4·5. G. = 4·06–4·09. From Sterling Hill, N. J. [The original investigation was, unfortunately, never completed.]

Hydrohalite.—App. II., p. 29.

Hydroilmenite.—See *Menaccanite*, p. 76.

Hydromagnesite.—App. II., p. 29.

Hydroniccite. A name suggested for a doubtful substance conjectured to be a hydrated oxide of nickel, Texas, Penn., *C. U. Shepard*, Min. Contr., 1877.

Hydrophilite.—See *Chlorocalcite*, p. 25.

Hydrorhodonite. *N. Engström*, Geol. För. Förh., ii., 468, 1875.
Massive; crystalline. Cleavage easy in one direction. H. = 5–6. G. = 2·70. Lustre vitreous. Color red-brown. Streak brownish white. Translucent, in thin splinters transparent. Fracture splintery. Analyses:

	SiO_2	MnO	FeO	MgO	CaO	Li_2O	Na_2O	H_2O		
1.	44·07	30·83	1·04	6·98	3·60	1·23	0·39	11·84	=	99·98.
2.	44·06	31·15	1·00	7·24	3·54	(LiCl, NaCl = 4·80)		11·96.		

Formula $RSiO_3 + H_2O$, or rhodonite plus a molecule of water. Soluble in HCl, with the separation of silica. B. B. fuses easily to an opaque, brownish red bead; reacts for manganese. The powdered mineral becomes black on heating. From Låugban, in Wermland, Sweden. [Perhaps simply a hydrated rhodonite.]

Hydrotitanite.—See *Perofskite*, p. 91.

Hygrophilite, App. II., p. 29.—Related mineral from Reuschbach, Palatinate, *Gümbel*, J. Min., 1878, 385.

Idrocastorite (Hydrocastorite).—See *Petalite*, p. 91.

Igelströmite.—See *Pyroaurite*, p. 99.

Ihlëite. *Schrauf*, J. Min., 1877, 252.
Amorphous. Forms an efflorescence on graphite, having a botryoidal or small reniform structure. G. = 1·812. Color orange yellow, becoming pale yellow in dry air. Analyses:

	SO_3	Al_2O_3,	Fe_2O_3	FeO	CaO	H_2O		
1.	38·2	24·5		2·1	...	35·5	=	100·3.
2.	37·4	0·3	26·1		0·4	35·6	=	99·8.
3.	37·2	25·6		1·4	0·3	35·3	=	99·8.

Formula perhaps $[Fe_2]S_3O_{12}$ + 12aq. = SO_3 38·96, Fe_2O_3 25·96, H_2O 35·07. Soluble in cold water. Occurs at the graphite deposits at Mugrau, Bohemia, owing its origin to the decomposition of imbedded crystals of pyrite. Named for Mr. Ihle, superintendent of mines in Mugrau. [Near coquimbite.]

Ilesite. *A. F. Wuensch*, Mining Index, Leadville, Colorado, Nov. 5, 1881. In loosely adherent crystalline aggregates, prismatic. Color white. Taste bitter, astringent. Friable. Analysis by M. W. Iles:

SO_3	MnO	ZnO	FeO	H_2O		
35·85	23·18	5·63	4·55	30·18	=	99·39.

This corresponds approximately to RSO_4 + 4aq., which, with R = Mn : Zn : Fe = 5 : 1 : 1, requires: SO_3 35·63, MnO 22·58, ZnO 5·15, FeO 4·58, H_2O 32·06 = 100. Readily soluble in water. Occurs in a siliceous gangue with the sulphides of iron and zinc (from which it has been formed), in veins 2 to 8 inches wide. Locality in Hall Valley, Park Co., Colorado. Named after Dr. M. W. Iles, of Leadville.

ILMENITE.—See *Menaccanite*, p. 76.

ILMENORUTILE.—See *Rutile*, p. 105.

ILSEMANNITE.—App. I., p. 7.

ILVAITE, Min., p. 296; App. II., p. 30.—**Analyses**, (1), Elba, *Sipöcz* (Min. Mitth., 1875, 72), an unaltered crystal; (2), *Early*, quoted by Reynolds (Chem. News, xxxvi., 85, 1877), Proc. Roy. Ir. Acad., II., iii., 52, 1877.

		SiO_2	Fe_2O_3	FeO	MnO	CaO	H_2O	
1.	G. = 4·037 (½)	29·67	21·26	33·09	0·74	13·33	2·32	= 100·41.
2.		29·93	20·16	31·83	3·02	13·71	0·42,	Al_2O_3 0·36, MgO 0·30, K_2O 0·20, [Na_2O 0·29 = 100·22.

Sipöcz makes the water essential, and adopts the formula of Städeler: $R_7[R_2]\,Si_4O_{18}$, or $H_2Ca_2Fe_4\,[Fe_2]Si_4O_{18}$; Reynolds neglects the water, and writes: $R_6[R_2]Si_4O_{17}$, or $Ca_2(Fe, Mn)_4[Fe_2]Si_4O_{17}$.

According to Websky, isomorphous with humite, Ber. Ak. Berlin, 1876, 201.

Indianaite.—See *Halloysite*, p. 55.

Iodobromite. *A. von Lasaulx*, J. Min., 1878, 619.

Isometric, in octahedrons with cubic planes. Cleavage octahedral indistinct. G. = 5·713. Color sulphur yellow, sometimes greenish. Sectile. Composition: 2 Ag (Cl,Br) + Ag I = Cl 7·79, Br 17·18, I 14·15, Ag 60·88 = 100. Analysis, Lasaulx (l. c.):

Cl	Br	I	Ag	
7·09	17·30	15·05	59·96	= 99·40.

B. B. gives off bromine vapors and leaves a silver globule. Found in small cavities in ferruginous quartz at the mine "Schöne Aussicht," near Dernbach, Nassau, associated with beudantite, carminite, and probably greenockite.

IODYRITE, Min., p. 117.—Artificial crystals, hemimorphic, *v. Zepharovich*, Z. Kryst., iv., 119, 1879.

Cryst., Dernbach, Nassau, *Seligmann*, Corr. Bl. Nat. Ver. Bonn, xxxvii., 130, 1880.

Ionite. *S. Purnell*, Am. J. Sc., III., xvi., 153, August, 1878.

A fossil hydrocarbon found in a more or less impure condition in the lignite of Ione Valley, Amador County, California. Structure firm, earthy. Color brownish yellow. Partially soluble in cold alcohol, largely soluble in ether, completely so in chloroform. A brown tarry oil containing a small quantity of paraffine is separated by dry distillation. Exact chemical nature unknown.

IRIDIUM, Min., p. 12.—Cryst., Ural, *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xiv., 155, 1879 (Z. Kryst., iii., 437).

IRIDOSMINE, Min., p. 12.—(Nefdanskite), *v. Kokscharof*, Min. Russl., vi., 237, 239, 1874.

IRON, Min., p. 15; App. II., p. 30.—The native iron of Ovifak, Disco Bay, Greenland, discovered by *Nordenskiöld* in 1870 (Œfv. Ak. Stockh., 1870, 1058, and 1871, 1, or Geol. Mag., ix., 1872), and by him regarded as of meteoric origin, has been exhaustively studied both in its geognostic and chemical relations:—See *Nordström*, Œfv. Ak. Stockh., 1871, 453; *Nauckhoff*, ib., Bihang, i., April, 1872 (or Min. Mitth., 1874, 109); *Daubrée*, C. R., lxxiv., 1546, 1872, and lxxv., 240, 1872, and lxxxiv., 66, 1877; *Wöhler*, Gött. Gelehrt. Anzeig., 1872, 197, and J. Min., 1879, 832; *Tschermak*, Min. Mitth., 1874, 165; *Steenstrup*, Ved. Medd. Copenhagen, 1875, Nos. 16–19 (or ZS. G. Ges., xxviii., 225, 1876); *Törnebohm*, Œfv. Ak. Stockh., Bihang, 1878; *Meunier*, C. R., lxxxix., 215, 1879; *J. Lawrence Smith*, Ann. Ch. Phys., V., xvi., 452, 1879. The observations of Steenstrup, and later more particularly those of Törnebohm and Smith make it very certain that the iron is not meteoric but of terrestrial origin.

Iserite.—See *Rutile*, p. 105.

ISOCLASITE.—App. I., p. 7.

ITTNERITE, Min., p. 333.—It is concluded by *van Werveke* on the basis of a microscopical and chemical examination that ittnerite and skolopsite belong together, and that both are results of the partial alteration of haüynite (J. Min., 1880, ii., 264). This confirms the conclusion of Rammelsberg (Syst. Min., p. 333, and Min. Chem., 2d ed., p. 459).

Ivigtite.—App. I., p. 7.

Jacobsite, App. I., p. 8.—Långban, Wermland, Sweden, anal. by Lindström: Fe_2O_3 58·39, Mn_2O_3 6·96, MnO 29·93, MgO 1·68, CaO 0·40, PbO 1·22, P_2O_5 0·06, insol. 2·17 = 100·81. This corresponds to $Mn\,[Fe_2, Mn_2]\,O_4$; quoted by *Nordenskiöld*, Geol. För. Förh., iii., 384, 1877.

Jadeite, Min., p. 292.—Analyses of related minerals, *Damour*, Bull. Soc. Min., iv., 157, 1881.

Occurrence at the Vulture mine, Arizona, *Silliman*, Am. J. Sc., III., xviii., 73, 1879; anal. (1), *Penfield*, ib., xxi., 160, 1881. Occurrence at the Arrow mine, Chaffee Co., Colorado, and anal. (2), *König*, Am. Chem. Journ., ii., 375, 1881. Occurrence in the province of Cajamarca, Peru, *Ramondi*, Min. Pérou, p. 234, 1878.

		SO_3	Fe_2O_3	K_2O	Na_2O	H_2O	SiO_2
1.	G. = 3·09	30·42	48·27	8·58	0·28	[11·42]	1·08 = 100.
2.	G. = 3·144	29·33	52·36	7·30	0·90	10·55	.... = 100·44.

The water determined in (1), viz., 12·91, was too high, the result obtained by difference is nearer correct. In (2), the silica has been deducted, and 8·8 p. c. of turgite remains to be rejected. The formula is then $K_2[Fe_2]_3S_4O_{22}$, $6H_2O = K_2SO_4 + [Fe_2]S_3O_{12} + 2[Fe_2]H_6O_6$.

Jaulingite, Min., p. 800.—A related resin ($C_{20}H_{42}O_2$), from Köflach, Styria, for which the name köflachite is provisionally suggested by *Dölter*, J. Min., 1880, ii., 152 (ref.).

Kelyphite. *Schrauf*, Verh. G. Reichs., 1879, 244. Gray serpentinous coating of pyrope crystals from Kremze, near Budweis, Bohemia. The pyrope has been analyzed by *Scharizer*.

KENNGOTTITE.—See *Miargyrite*, p. 77

Kentrolite. *Damour* and *vom Rath*, Z. Kryst., v., 32, 1880.

Orthorhombic; axes, c (vert.) : $\breve{b}$: $\breve{a}$ = 0·784, 1 : 0·633. Observed planes: *I*, 1, and *i*-*ĭ* small. $I \wedge I = 115° 18'$, $1 \wedge 1$ (terminal) = 87° 29′ and 125° 32′. Cleavage: prismatic, distinct. Crystals minute, often grouped in sheaf-like forms resembling stilbite, planes rough, and the prismatic horizontally striated. Also massive. H. = 5. G. = 6·19 Color dark reddish brown, on the surface blackish (vom Rath). Analysis, Damour:

SiO_2	MnO_2	PbO	
15·95	24·50 (or Mn_2O_3 22·26)	59·79	= 100·24.

The state of oxidation of the manganese, and hence the true composition of the mineral, is left in doubt; on the first supposition it is expressed $Pb\overset{iv}{M}nSiO_5$, which requires: SiO_2 16·21, MnO_2 23·52, PbO 60·27 = 100; on the second it is $Pb_2[Mn_2]Si_2O_9$, which requires: SiO_2 16·58, Mn_2O_3 21·83, PbO 61·59 = 100. [The latter formula is the more probable one; see *Melanotekite*, p. 75.] B. B. on charcoal gives a lead coating and with soda a globule of lead. In a salt of phosphorus bead dissolves and gives in R. F. a slight yellowish color, after the addition of saltpeter becomes bright violet. Dissolves in part in dilute sulphuric acid with the separation of manganese oxide and silica. With HCl chlorine is disengaged. From southern Chili, exact locality unknown. Occurs with quartz, barite, apatite. Named from *κέντρον*, *spike*. Websky calls attention to the fact that the angles of kentrolite agree very closely with those of descloizite (Z. Kryst., v., 552).

KRAURITE.—See *Dufrenite*, p. 39.

Krennerite. BUNSENIN, *Krenner*, Termesz. Füzetek, 1877 (Wied. Ann., i., 637). KRENNERITE, *vom Rath*, Ber. Ak. Berlin, 1877, 292 (Z. Kryst., i., 614, 1877). *Schrauf*, ib., ii. 235, 1878.

Orthorhombic (monoclinic? Schrauf). Axes: c (vert.) : $\bar{b}$: $\breve{a}$ = ·50445 : 1 : ·94071. Observed planes : O, $i\text{-}\breve{i}$, $i\text{-}\bar{i}$, I, $i\text{-}2$, $i\text{-}\frac{3}{2}$, $i\text{-}\breve{2}$, $i\text{-}\breve{3}$, 1, $2\text{-}\breve{i}$, $3\text{-}\breve{i}$, $1\text{-}\breve{i}$, $\frac{1}{2}\text{-}\breve{i}$, $1\text{-}\bar{i}$, 1, $1\text{-}\breve{2}$, $\frac{3}{2}\text{-}\bar{i}$. $I \wedge I = 93° 30'$; $O \wedge 1\text{-}\breve{i} = 151° 48'$; $O \wedge 1\text{-}\bar{i} = 153° 14'$: $O \wedge 1 = 143° 39'$. In vertically striated prismatic crystals. Cleavage: basal perfect (v. Rath). Lustre metallic, brilliant. Color silver white to brass yellow. Opaque. Brittle.

Contains gold and tellurium, with a little silver and copper, but exact composition not yet determined; Schrauf obtained from an approximate blowpipe analysis, Au + Ag (Pb?) 52 or Au 31. B. B. decrepitates violently. Found at Nagyag, Transylvania, associated with quartz and pyrite. Related to sylvanite in the angles of two zones, but different in others. Also related in composition to calaverite.

This is the mineral, according to Krenner and Schrauf, which has formerly gone by the names gelberz, weisstellur, müllerine, etc., see Min., p 81.

As the name bunsenite has been accepted for the nickel protoxide from Johanngeorgenstadt, vom Rath has given this mineral the name krennerite from the original discoverer.

Krönnkite. *I. Domeyko*, 5th Appendix Min. Chili, 1876; also 3d ed. Min. Chili, p. 250, 1879.

Triclinic (?). In irregular prismatic crystalline masses with coarsely fibrous structure. Cleavage distinct parallel to an edge of the prism. G. = 2·5. Lustre vitreous. Color azure blue, changing somewhat on exposure to the air. Composition: $CuSO_4 + Na_2SO_4 + 2aq$ = copper sulphate 47·23, sodium sulphate 42·09, water 10·68 = 100. Analysis by Krönnke : $CuSO_4$ 46·28, Na_2SO_4 42·95, H_2O 10·77 = 100. Perfectly soluble in water. Found in the copper mines near Calama, on the road from Cabija to Potosi, Bolivia.

Krugite.—See *Polyhalite*, p. 96.

LABRADORITE, Min., p. 341; App. II., p. 32.—**Anal.**, Adirondacks, N. Y., ***Leeds***, Amer. Ch., March, 1877. Arvieu, Arveyron, ***Pisani***, C. R., lxxxvi., 1420, 1878. ***Klement***, Min. Petr. Mitth., i, 366, 1878; ***Schuster***, ib., p. 367.

See also *Feldspar Group*, p. 45.

LANARKITE, Min., p. 628; App. II., p. 33.—**Cryst.** description, with correction of previously accepted angles, ***Schrauf***, Z. Kryst., i., 31, 1877.

LANGITE.—Min., p. 665; App. II., p. 33.

LAPIS LAZULI.—Min., p. 334; App. II., p. 33.

LAUMONTITE, Min., p. 399; App. II., p. 33.—**Anal.**, New South Wales, *Liversidge*, Min. Mag., i., 54, 1876. Monte Catini, *Bechi*, Accad. Linc. Trans., III., iii., 114, 1879.

Analysis by *A. Smita* (Min. Mitth., 1877, 268), of LEONHARDITE from the Floitenthal (see Brezina, ib., 1877, 98) gave: SiO_2 52·92, Al_2O_3 22·44, CaO 12·23, H_2O 12·38 = 99·97, for material dried over sulphuric acid, and SiO_2 60·15, Al_2O_3 25·91, CaO 14·19 = 100·25 for ignited material. The first corresponds with the previously accepted formula: $Si_4[Al_2]CaH_8O_{16}$, which, however, expresses the composition of the mineral only after it has lost in dry air, or at 100°, a part of its water. Smita confirms the conclusion that leonhardite is to be referred to laumontite, differing from it only in having lost a part of the water which goes off at 100°.

LAURITE, Min., p. 74; App. II., p. 33.—Artificially prepared, *St. Claire Deville* and *Debray*, Bull. Soc. Min., ii., 185, 1879.

Lautite. *Frenzel*, Min. Petr. Mitth., iii., 515; iv., 97, 1881.

In small brilliant crystals, short prismatic, with *I*, *i*-*ĭ* and *O*; orthorhombic. Generally massive; compact. Columnar to fine fibrous, radiated, also fine granular. H. = 3–3·5. G. = 4·96. Lustre metallic. Color iron black. Streak black. Opaque. Not brittle.

Analyses, Frenzel:

	S	As	Sb	Ag	Cu	
1.	18·00	42·06	....	11·74	27·60	= 99·40.
2.	17·60	41·06	....	11·62	28·29	= 98·57.
3.	18·57	42·60	0·58	3·03	33·54, Fe 0·44	= 98·76.

The iron in (3) is due to chalcopyrite; another determination of the silver gave 7·78 p. c. Formula deduced CuAsS [see below], with Ag replacing in part the Cu, this requires: S 18·78, As 44·01, Cu 37·21 = 100. B. B. decrepitates violently; fuses easily, giving off arsenical fumes. In the closed tube yields an arsenical mirror. Soluble in nitric acid; gives with hydrochloric acid a silver chloride precipitate. Found at Lauta, near Marienberg, Saxony; accompanied by metallic arsenic, ruby silver, tetrahedrite, chalcopyrite, galenite, and barite. [A homogeneous mineral? May it not contain metallic arsenic?]

LAVENDULAN, Min., p. 560.—**Anal.**, Chili, *Goldsmith*, Proc. Ac. Nat. Sc. Philad., p. 192, 1877.

LAVROFFITE.—Min., p. 216; App. II., p. 33.

Lawrencite. *Daubrée*, C. R., lxxxiv., 66, Jan., 1877.

Iron protochloride, shown by Daubrée to be present in the Greenland native iron. Named after Dr. J. Lawrence Smith, of Louisville, Ky., who detected the same substance in the meteoric iron of Tazewell. Daubrée also uses the name STAGMATITE (from σταγμα, *drop*).

LAXMANNITE.—App. I., p. 9.

LAZULITE, Min., p. 572; App. II., p. 33.—**Anal.**, discussion of formula, Zermatt, *Gamper*, Jahrb. G. Reichs., 1878, 611. Canada, *Hoffmann*, Geol. Canada, Rep., 1879–80 (Am. J. Sc., III., xxi., 410).

LEAD, Min., p. 17; App. II., p. 33.—Russia, occurrence, *v. Kokscharof*, Min. Russl., vi., 236. Huancavelica, Peru, *Raimondi*, Min. Pérou, p. 145, 1878.

LEADHILLITE, Min., p. 624; App. II., p. 33.—*Laspeyres* (Z. Kryst., i., 193, 1877) finally concludes that his supposed species, MAXITE (App. II., p. 38), is really identical with leadhillite. The crystalline form is monoclinic, according to him, with $\beta = 89° 48'$, and the composition is expressed by the empirical formula $H_{10}Pb_{18}C_9S_5O_{56}$, which requires SO_3 8·17, CO_2 8·08, PbO 81·91, H_2O 1·84 = 100 (see also J. pr. Ch., xi., 26, 1874; xii., 347, 1876; xiii., 370, 1876). The extremely complex character of the formula makes it somewhat improbable.

Bertrand (C. R., lxxxvi., 348, 1878) describes leadhillite from Matlock, Derbyshire, with 2E = 72° yellow (Sardinia and Scotch crystals have 2E = 21°); the angle diminishes with rise in temperature, and finally 2E = 66° at 250°; above this point the crystals fly to pieces. As bearing upon the question of the independent character of susannite, Bertrand describes crystals from Leadhills, in which he finds gray colored spots with 2E = 21°, and green colored spots which are uniaxial. The species leadhillite and susannite are probably identical.

Leidyite. *König*, Proc. Acad. Nat. Sc. Philad., 1878, 84.

In verruciform incrustations, consisting of fine scales with silky lustre; also stalactitic: crystalline (?). H. = 1–2. Lustre resinous. Color grass-, blue-, or olive-green. Streak white. Analysis:

SiO_2	Al_2O_3	FeO	MgO	CaO	H_2O		
51·41	16·82	8·50	3·07	3·15	17·08	=	100·03.

The formula calculated by the author is $R_2[Al_2]Si_5O_{15} + 5aq$, with R = Fe, Ca, Mg, H_2. B. B fuses with intumescence to a light yellow green glass. In the closed tube gives off water and becomes brown. Soluble readily in HCl, with partial gelatinization; after ignition insoluble. Found with grossular garnet, zoisite, and quartz, at Leiperville, Delaware Co., Penn. Named after Dr. Joseph Leidy, of Philadelphia.

LEONHARDITE.—See *Laumontite*, p. 67.

LEPIDOLITE.—Min., p. 314; App. II., p. 33.—See *Mica Group*, p. 77.

Lepidophæite.—See *Wad*, p. 130.

LESLEYITE.—App. I., p. 18.

LETTSOMITE, Min., p. 666.—Anal., La Garonne, Dept. du Var, *Pisani*, C. R., lxxxvi. 1418, 1878. Optical characters investigated, *Bertrand*, Bull. Soc. Min., iv., 11, 1881.

LEUCHTENBERGITE, Min., p. 500; App. II., p. 34.—Microscopic examination, *v. Leuchtenberg*, Bull. Ac. St. Pet., xxi., 509, 1876.

LEUCITE, Min., p. 334; App. II., p. 34.—The question as to the true crystalline system of leucite has been discussed, as follows: *Hirschwald*, Min. Mitth., 1875, 227; *Tschermak*, Min. Mitth., 1876, 66 (anal. by Berwerth); *vom Rath*, J. Min., 1876, 281, 403; *Hirschwald*, J. Min., 1876, 519, 733; *Baumhauer*, Z. Kryst., i., 257, 1877; *Hirschwald*, Min. Petr. Mitth., i., 85, 1878; *Bammhauer*, Min. Petr. Mitth, i., 287, 1878; *Groth*, Z. Kryst., v., 264, 1880; *Weisbach*, J. Min., 1880, i., 143; also *Mallard*, Ann. Min., VII., x., 79, 1876. Hirschwald maintains that the species is, in fact, isometric, with polysynthetic structure. This view is opposed by Bammhauer, vom Rath, and Groth, and the results of a series of experiments on the etching of the crystalline faces seem to prove its tetragonal nature. Mallard regards leucite as pseudo-isometric, referring it to the orthorhombic system, and later, Weisbach, on the basis of a series of measurements by Treptow, has reached a similar conclusion.

Fouqué and *Lévy* have succeeded in obtaining artificial crystals of leucite (C. R., lxxxvii., 961, 1878, and Bull. Soc. Min., iii., 118, 1880); and *Hautefeuille* (C. R., xc., 313, 378, 1880) has formed an iron leucite, containing iron in place of the alumina. In both cases the same twinning is observed, and the same optical characters as in natural crystals.

Analyses by *Berwerth*, Acquacetosa, near Rome (Min. Mitth., 1876, 66); *Schulze*, Albani Mts., J. Min., 1880, ii., 114. Occurrence on the island of Bawean, Dutch East Indies, Vogelsang-Zirkel, J. Min., 1875, 175.

Leucochalcite. *Sandberger; Petersen*, J. Min., 1881, i., 263.
In very slender, needle-like crystals. Nearly white, with tinge of green. Lustre silky. Analysis: As_2O_5[37·89], P_2O_5 1·60, CuO 47·10, CaO 1·56, MgO 2·28, ign. 9·57 = 100; corresponding to $Cu_4As_2O_9 + 3H_2O$, or $Cu_3As_2O_8 + CuH_2O_2 + 2aq$, which requires: As_2O_5 42·75, CuO 47·21, H_2O 10·04 = 100. Becomes first green on ignition, and finally fuses to a black glass. Occurs as a delicate coating with malachite and calcite. Wilhemine mine in the Spessart. [A more complete description is to be desired; the mineral is apparently an arsenical tagilite.]

Leucomanganite. *Sandberger*, J. Min., 1879, 370. Announced as a snow-white mineral, in broad foliated-radiated aggregates. B. B. becomes brownish black, and fuses easily. Contains MnO, FeO, alkalies and water. From Rabenstein, near Zwiesel. [Needs further examination. Is it related to fairfieldite?]

LEUCOPHANITE, Min., p. 260; App. II., p. 34.—*Bertrand* (Phil. Mag., V., iii., 357, 1877) concludes on optical grounds that leucophanite is to be considered either as monoclinic or hemihedral orthorhombic. *Groth* (Z. Kryst., ii., 199, 1878) proves that the crystals are really monoclinic, and deduces the axial relations, $\dot{c}$ (vert.) : $\bar{b}$: $\grave{a}$ = 1·054 : 1 : 1·061; β = 90° approx. Groth describes twins and fourlings analogous to harmotome.

Rammelsberg (ZS. G. Ges., xxviii., 57, 1876) publishes some new analyses, and deduces the formula: $R_{16}Si_{14}O_{48} + 6NaF$ with R = Be : Ca = 1 : 1; this requires: SiO_2 49·35, BeO 11·16, CaO 24·68, Na_2O 10·93, F 6·69 = 102·81.

LEUCOPYRITE.—Min., p. 77; App. II., p. 34.

Leucoxene.—See *Titanomorphite*, p. 122.

Leucotile. *Hare*, Inaug. Diss. Breslau, 1879 (Z. Kryst., iv., 295).
In fibres irregularly grouped on serpentine. Cleavable, parallel and perpendicular to the longitudinal direction; optically orthorhombic (?). Lustre silky. Color green. Analysis:

SiO_2	Al_2O_3	Fe_2O_3	MgO	CaO	Na_2O	K_2O	H_2O	
28·98	6·99	8·16	29·78	7·37	1·32	tr.	17·29	= 99·89.

This corresponds nearly to $R_8[R_2]Si_4O_{19}, 8H_2O$. Easily soluble in HCl and H_2SO_4. B. B. fuses and becomes slightly yellow, and yellowish brown. From Reichenstein, Silesia.

Leviglianite.—See *Onofrite*, p. 86.

LEVYNITE.—Min., p. 431; App. II., p. 34. See also *Chabazite*, p. 22.

LIBETHENITE, Min., p. 563.—**Cryst.**, pseudo-orthorhombic (monoclinic), according to *Schrauf*, Z. Kryst., iv., 19, 1879.
Made artificially, *Friedel* and *Sarasin*, Bull. Soc. Min., ii., 157, 1879.

Argentine Republic, anal., *Frenzel*, J. Min., 1875, 675; cryst., *v. Rath*, Z. Kryst., iv., 426, 1880.
Anal., State of Jalisco, Mexico, *Barcena*, Naturaleza, iv., 55, 1877.

LINNÆITE, Min., p. 68.—Analyses, P. T. Cleve (Geol. För. Förh., i., 125, 1872), 1, Bastnäs, 2, Gladhammar:

	S	Co	Ni	Cu	Fe		
1. Bastnäs, G. = 4·755.	41·83	44·92	0·19	8·22	4·19	=	99·35.
2. Gladhammar, G. = 4·825.	42·19	39·33	12·33	2·28	4·29	=	100·42.

Both correspond closely to the formula $2RS + RS_2$, or RS, R_2S_3.

Lintonite.—See *Thomsonite*, p. 121.

Lionite.—See *Tellurium*, p. 119.

Liskeardite. *Maskelyne*, Nature, Aug. 15, 1878.
Massive; in thin incrusting layers, with uniform fibrous structure. Color white, with a slight blue or greenish-blue tint. Composition stated to be $[R_2]_3As_2O_{14}, 16H_2O$, with $[R_2] = [Al_2]$ and some $[Fe_2]$, according to an analysis by Dr. Flight (not published) Liskeard, Cornwall. An arsenical evansite, Min., p. 585. [A more complete description is to be desired.]

Lithiophilite.—See *Triphylite*, p. 124.

LITHIOPHORITE, App. I., p. 9.—See *Psilomelane*, p. 98.

Litidionite (Lithidionite). *E. Scacchi*, Rend. Accad. Napoli, Dec., 1880.
Blue lapilli, found at Vesuvius in 1873, 7 to 25 mm. in diameter, were found to consist of a white earthy substance, with a glassy blue crust. Of the latter, H. = 5–6, G. = 2·535. The mean of two analyses gave, after being washed: SiO_2 71·57, CuO 6·49, FeO 4·02, K_2O 10·92, Na_2O 6·78 = 99·78. Slightly attacked by HCl; fuses very easily (the white nucleus, consisting of augite, olivine, etc., is infusible). The author, on the ground of the fusibility, regards the substance as a mixture of quartz and the carbonates of potassium and sodium. [The name, obviously, does not belong to a definite species, why it was given does not appear.]

LIVINGSTONITE, App. II., p. 35.—Analysis by *F. P. Venable* (Chem. News, xl., 186, 1879), after deducting impurities: (½) S 23·73, Sb 53·75, Hg 22·52 = 100, for which the formula $HgS + 2Sb_2S_3$ is given (but Groth suggests $Hg_2S + 4Sb_2S_3$, Z. Kryst., vi., 97). Anal. by Barcena: S 22·97, Sb 53·12, Hg 20·00, gangue and loss 3·91 = 100, Naturaleza, iv., 268, 1879. From Guadalcazar, Mexico, anal. by *Page*, Ch. News, xlii., 195, 1880.
Made artificially, *Baker*, Ch. News, xlii., 196, 1880.

LÖLLINGITE, Min., p. 76; App. II., pp., 35, 34.—Anal. (sätersbergite, $FeAs_2$), Brevig, Norway, *Nordenskiöld*, Geol. För. Förh., ii., 242, 1875. Monte Challanches, Dauphiny, in crystals, *Frenzel*, J. Min., 1875, 677. In serpentine of Reichenstein, Silesia, *Hare*, Z. Kryst., iv., 295.

Louisite. *Honeymann*, Proc. Nova Scotia Inst. Nat. Sc., v., 15, 1878.
A transparent, glassy, leek green mineral; streak white; fracture splintery. H. = 6·5. G. = 2·41. Gelatinizes with HCl. An analysis by H. Louis gave: SiO_2 63·74, Al_2O_3 0·57, FeO 1·25, MnO tr., CaO 17·27, MgO 0·38, K_2O 3·38, Na_2O 0·08, H_2O 12·96 = 99·63. [Needs further examination; free silica is very probably present.]

Luckite.—See *Melanterite*, p. 76.

Ludlamite. *N. Story-Maskelyne* and *F. Field*, Phil. Mag., V., iii., 52, 135, 525, 1877.
Monoclinic. Axes, $\dot{c}$ (vert.) : $\breve{b}$: $\bar{a}$ = 1·9820 : 1 : 2·2527. β = 79° 27′. Observed planes. O, $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, I, 1, −1, $-\frac{1}{2}$, $1\text{-}\breve{i}$, $-2\text{-}\bar{i}$, $1\text{-}\bar{i}$, $2\text{-}\bar{i}$. $O \wedge i\text{-}\bar{i}$ = 100° 33′, $O \wedge 1\text{-}\bar{i}$ = 117° 10′; $I \wedge I$ = 131° 23′; $O \wedge -1$ = 118° 35′. $O \wedge 1$ = 111° 29′. O and 1 striated parallel to intersection-edge. Cleavage: O highly perfect; $i\text{-}\bar{i}$ distinct. Optic-axial plane, the clinodiagonal. Acute bisectrix positive, inclined 67° 5′ to the vertical axis in the acute angle of the

axes *cd*. Axial angles: $2H_a = 97° 50'$, $2H_o = 119°$, and hence $2V = 82° 22'$. Dispersion of the bisectrices almost zero, of the axes small $\rho > v$.

H. = 3–4. G. = 3·12. Lustre brilliant. Color bright green. Streak greenish white. Transparent. Analysis (mean of several):

P_2O_5	FeO	H_2O		
30·11	52·76	16·98	=	99·85.

This corresponds to $Fe_7P_4O_{17}, 9H_2O$ (or $H_2Fe_7P_4O_{18} + 8aq$) = P_2O_5 29·89, FeO 53·06, H_2O 17·05 = 100. B. B. colors the flame pale green, and leaves a black residue. In the closed tube decrepitates violently, becomes dark blue, and gives off water. Soluble in dilute hydrochloric and sulphuric acids.

Occurs with siderite, vivianite, pyrite, at the Wheal Jane mine, near Truro, Cornwall. Named after Mr. Ludlam, of London.

LUDWIGITE.—App. II., p. 35.

LÜNEBURGITE.—App. I., p. 10.

LUNNITE.—See *Pseudomalachite*, p. 97.

LUZONITE, App. II., p. 85.—See *Clarite*, p. 27.

Macfarlanite. The occurrence at Silver Islet, Lake Superior, with the metallic silver, of thin plates and grains of a reddish-brown sectile mineral, containing As, Ag, Co, Ni, and supposed to be new, was described by *T. Macfarlane* in 1870 (Can. Nat., Feb. 1). To the granular ore, or mixture of reddish-colored grains with other minerals, the name MACFARLANITE was given, later, by Major Sibley (quoted by *Macfarlane*, Trans. Amer. Inst. Min. Eng., viii., 236, 1880; see also *Courtis*, Eng. Min. J., xxvii., March 29, 1879). In 1879 *Wurtz* described two supposed new minerals from Silver Islet, HUNTILITE (Eng. Min. J., xxvii., 55, 1879) and ANIMIKITE (ib., p. 124). His descriptions are as follows:

HUNTILITE.—In two varieties: (*A*) Of a dark gray or more commonly black color; dull, amorphous, porous, and fragmentary; (*B*) apparently crystalline; one cleavage direction; bright slate color, and occurs imbedded in calcite. (*A*) is the more common. Semi-malleable. H. less than 2·5. G. = 7·47 (*A*), 6·27 (*B*), after deduction of impurities. Analyses:

	As	Sb	S	Ag	Hg	Co	Ni	Fe	Zn	H_2O	gangue.		
A	21·10	3·33	0·78	59·00	1·04	3·92	1·96	3·06	2·42	0·19	3·23*	=	100·03.
B	23·99	4·25	1·81	44·67	1·11	7·33	2·11	3·53	3·05	0·33	1·65*	=	93·83.

* (*A*) Silicate 0·88, calcite 2·35; (*B*) do. 0·55 and 1·10.

The author proposes to subtract the Hg as amalgam, and S as pyrite, and then calculating the remaining metals as Ag ($\overset{\text{II}}{R} = 2\overset{\text{I}}{R}$), he obtains the ratio of $\overset{\text{I}}{R}$: As (+ Sb) = 2·90 : 1 for *A*, and 2·99 : 1 for *B*. On the basis of this, the formula Ag_3As is assumed as representing the composition. Named after Dr. T. Sterry Hunt. [No value can be attached to the formula deduced (see below), for most of the metals thus taken together are present only as impurities. Compare Arsenargentite, p. 9.]

ANIMIKITE.—Occurs as an incrustation on huntilite, also in isolated slabs or plates. Structure fine-granular, crypto-crystalline. G. = 9·45. Color white to grayish white. Fracture semi-conchoidal or granular. Somewhat sectile. An analysis yielded:

Sb	As	S	Ag	Hg	Co	Ni	Fe	Zn	gangue.		
11·18	0·35	1·49	77·58	0·99	2·10	1·90	1·68	0·36	1·68	=	99·31.

From the Silver Islet mine, Lake Superior. Named from "animikie," *thunder*, whence Thunder Bay. The formula Ag_9Sb is proposed.

The complex relations of the above minerals and mineral mixtures has been well investigated by *Macfarlane* (l. c.). The granular ore was found to be made up of reddish-brown metallic grains, when polished looking like burnished nickel, with an undetermined black mineral, niccolite, galena, calcite, and quartz. The ore, pulverized and freed from all brittle materials by washing, yielded 75 to 84 p. c. silver; the grains finally obtained by repeated trituration and sifting had a dark gray color, and gave 92 p. c. silver: on solution in dilute nitric acid these grains yielded: Ag 93·54, Ni 1·58, As 2 15, Sb 0·36, insol. 2·37 = 100. The insoluble portion (2·37 p. c.) assayed 17·46 p. c. silver.

A quantity of the original metallic grains were acted upon by three successive portions of very dilute nitric acid. The results were:

	Ag	Hg	Ni	As	Sb		
1.	37·64	0·65	4·66	6·40	0·17	=	49·52.
2.	33·69	0·10	1·22	....	0·06	=	35·07.
3.	5·40	....	tr.	....	tr.	=	5·40.

There remained 6·20 p. c. insol. (quartz, etc.), and 3·77 p. c. of a black mineral washed from the quartz, containing 24·8 p. c. Ag, also Sb, S, Pb, Co, Ni. The author closes by stating very justly, that further investigation is needed to determine the character of the various minerals present.

König (Proc. Acad. Nat. Sc. Philad., 1877, 276) has analyzed a similar mineral mixture from Silver Islet: As 10·56, Sb tr., S 1·81, PbS 38·18, Ag 32·68, Ni, Co 8·96, Fe 0·35, quartz 6·00, $CaCO_3$ 1·20 = 99·74. He regards the nickel and arsenic as combined and forming niccolite, which exists mixed with galenite, argentite, and probably a basic silver arsenide.

[It would appear from the above, that the true nature of the individual minerals present in the Silver Islet ores is still to be determined, but that there is probably present a silver arsenide (*huntilite*), and perhaps also a silver antimonide (*animikite*) allied to dyscrasite.]

MACONITE.—App. II., p. 36.

MAGNESITE, Min., p. 685; App. II., p. 36.—Massive var. from Elmen, Eastern Alps (anal. by Lehmayer), *Gümbel*, Verh. G. Reichs., 1880, 276.

MAGNETITE, Min., p. 149; App. II., p. 36.—**Cryst.**, Vesuvius, *Scacchi*, Contrib. Min., ii., 3. Albani Mts., Latium, *Strüver*, Z. Kryst., i., 230, 1877. Binnenthal, with implanted rutile crystals in parallel position, *Seligmann*, Z. Kryst., i., 340; do. with hematite, same locality, *Bücking*, ib., i., 575. Jerofeief (Verh. Min. Ges. St. Pet., II., xvii., 24), Min. Russl., viii., 226, 1881.

Coercive force, *Holz*, Wied. Ann., v., 169, 1878.

Anal., Kaiserstuhl (4·08 p. c. TiO_2), *Knop*, Z. Kryst., i., 64, 1877. Magnet Cove (3 25 p. c. TiO_2), *König*, Pr. Am. Ac. Nat. Sc. Philad., 1877, 293. Kristianstad, Sweden (by Nordström, 6·01 p. c. TiO_2), *Karlsson*, Geol. För. Förh., i., 14, 1872.

With melanite on trap, East Rock, New Haven, *E. S. Dana*, Am. J. Sc., III., xiv., 217, 1877.

MAGNOCHROMITE.—App. II., p. 36.

Magnolite. *F. A. Genth*, Amer. Phil. Soc. Phil., xvii., 118, 1877.

In radiating tufts of very minute acicular or capillary crystals. Color white. Lustre silky. Contains mercury and tellurium, and composition inferred to be Hg_2TeO_4. Blackened by ammonia. A decomposition product of coloradoite, found in the upper part of the Keystone mine, Magnolia District, Colorado. [Needs further examination.]

MALACHITE.—Min., p. 715; App. II., p. 37.

MALDONITE.—App. I., p. 10.

Malinofskite.—See *Tetrahedrite*, p. 120.

Mallardite. *Carnot*, Bull. Soc. Min., ii., 117, 1879.

In crystalline masses with fine fibrous structure; probably monoclinic (*Mallard*, ib., p. 119). Colorless. Analyses, 1, Rioult; 2, Carnot:

	SO_3	MnO	FeO	MgO	CaO	H_2O	Insol.		
1.	26·0	20·9	0·3	1·2	0·8	36·8	14·0	=	100·2.
2.	29 0	23·6	...	0·6	0·7	44·5	1·6	=	99·8.

This corresponds closely to the formula: $MnSO_4 + 7aq$, which brings it into the same group with melanterite, Min., p. 646. Easily soluble in water. Changes rapidly on exposure; effloresces, becomes opaque, and finally pulverulent. Is decomposed by strong heating, losing the sulphuric acid and water, and leaving a reddish-brown residue. Carnot obtained from a solution of manganese sulphate at 15° C. the salt, $MnSO_4 + 5aq$ in triclinic crystals; but at a temperature of 6° C. he obtained monoclinic crystals with the composition, $MnSO_4 + 7aq$.

Occurs in a gray clay-like gang stone, with quartz sand and barite. From the silver mine "Lucky Boy," south of Salt Lake, near Butterfield Cañon, Utah.

MANCINITE.—According to Uzielli (Trans. Accad. Linc., III., i., 108, 1877), the mineral called mancinite is not, as supposed, from the hill Mancino, near Leghorn, nor is it a zinc trisilicate, *Jacquot* (Ann. Min. III., xix., 703, 1841).

MANGANITE, Min., p. 170.—Cryst., monograph (Ilefeld), showing 4 types of forms with new planes, twins, etc., the crystals holohedrally developed, *Groth*, Min.-Samml. Strassburg, p. 79, 1878. *Sadebeck*, ZS. G. Ges., xxxi., 206, 1879.

Anal., Långban, Sweden, *Blomstrand*, Geol. För. Förh., ii., 183, 1874.

MANGANOPHYLLITE, App. II., p. 87.—Found at Jacobsberg and Långban, Wermland, Sweden, *Sjögren*, Geol. För. Förh., i., 64, 1872.

Manganosiderite.—See *Rhodochrosite*, p. 103.

Manganosite. *Blomstrand*, Geol. För. Förh., ii., 179, 1874; iii., 123, 1876. *Sjögren*, ii., 531; iii., 181, 1876; iv., 158, 1878.

Isometric. In minute crystals, showing the octahedron and dodecahedron, rarely the cube. Cleavage cubic. Isotropic. H. = 5–6. G. = 5·18. Lustre vitreous. Color emerald green on the fresh fracture, becoming black on exposure to the air. Analysis, Blomstrand, ib., ii., 182:

	MnO	FeO	MgO	CaO		
($\frac{3}{2}$)	98·04	0·42	1·71	0·16	=	100·33.

Formula: MnO, and hence isomorphous with periclasite. Dissolves with difficulty in strong nitric acid, forming a colorless solution. Occurs with pyrochroite and manganite, in a manganiferous dolomite (anal.: $CaCO_3$ 56·47, $MnCO_3$ 30·10, $MgCO_3$ 13·56, $FeCO_3$ 0·18 = 100·31, Blomstrand) at Långban, Wermland; also in calcite, brucite, or dolomite, with hausmannite, pyrochroite, garnet, etc., at the Mossgrufva, Nordmark, Sweden.

Mangantantalite.—See *Tantalite*, p. 118.

MARCASITE, Min., p. 75; App. II., p. 87.—Cryst., twins described, etc., *Groth*, Min.-Samml. Strassburg, p. 38, 1878. Cryst. association with pyrite, *Sadebeck*, Pogg. Ann., Erg.-Bd., viii., 625.

MARCYLITE, Min., p. 187.—*Raimondi* describes a mineral from the Cerro Verde, between Islay and Arequipa, Peru, which he concludes to be a mixture of a hydrated oxysulphide of copper, marcylite, with cuprite and atacamite. From the hacienda d'Ocucaje, province of Ica, he mentions another consisting of marcylite, atacamite, melaconite, and limonite, Min. Pérou, pp. 98, 101, 1878. [It has never been shown that the original marcylite was really a distinct species, and the Peruvian mineral seems to be no less uncertain.]

MARGARITE, Min., p. 506; App. II., p. 87.—See also App. III., *Mica Group*, p. 77, and *Clintonite Group*, p. 28.

MARIPOSITE.—App. II., p. 87.

Marmairolite. *N. O. Holst,* Geol. För. Förh., ii., 580, 1875.

In very fine crystalline needles, monoclinic (?). H. = 5. G. = 3·07. Color pale yellow. Powder white. Transparent. Analysis (mean of several):

SiO_2	FeO	MnO	MgO	CaO	K_2O	Na_2O	ign.	
56·27	2·03	4·86	21·36	6·33	1·89	5·94	0·90	= 99·58.

Formula approximately $RSiO_3$ (Q. ratio for R : Si = 18·75 : 30·02). B. B. fuses with some difficulty to an opaque bead. Not attacked by acids. Occurs with schefferite in a brownish manganesian limestone (containing 6·56 MnO, and 1·35 PbO), at Lángban, in Wermland, Sweden. Named from *μαρυαίρω, to glisten.* [Very near enstatite, except that it contains alkalies.]

MASCAGNITE, Min., p. 635.—In guano from the Guañape Iles, *Raimondi,* Min. Pérou, p. 32, 1878.

MASKELYNITE.—App. II., p. 37.

MASSICOT, Min., p. 136.—Occurrence, Cerro de Caracoles, Bolivia, *Domeyko,* 6th App. Min. Chili, p. 15, 1878.

MATLOCKITE, Min., p. 119.—**Anal.**, Montagne de Challacollo, Tarapaca, Peru, *Raimondi,* Min. Pérou, p. 170, 1878.

Matricite. *N. O. Holst,* Geol. För. Förh., ii., 528, 1875.

In crystalline masses with concentric, fine fibrous structure. H. = 3–4. G. = 2·53. Lustre pearly. Color gray, often with a greenish tinge. Streak white; subtranslucent to opaque. Fracture splintery to uneven. Feel greasy. Analysis (after the deduction of 28·36 p. c. $CaCO_3$ mechanically mixed):

SiO_2	MgO	CaO	Al_2O_3	FeO	MnO	Na_2O	H_2O	
33·99	37·96	5·64	1·33	1·82	0·47	0·98	17·81	= 100.

Formula $Mg_2SiO_4 + H_2O$. B. B. infusible. Yields water in the closed tube. Decomposed by acids with separation of silica, but does not gelatinize. Occurs intimately mixed with calcite and associated with spodiosite, at the Krangrufva in Wermland, Sweden. [Compare villarsite, Min., p. 409.]

MAXITE.—App. II., p. 38; see also *Leadhillite,* App. III., p. 67.

MEERSCHALUMINITE.—App. II., p. 38 (44).

MEIONITE, Min., p. 318; App. II., p. 38.—**Anal.**, by Neminar (Min. Mitth., 1875, 51; 1877, 61), gave: SiO_2 43·36, Al_2O_3 32·09, CaO 21·45, MgO 0·31, Na_2O 1·35, K_2O 0·76, H_2O 0·27, Cl 0·14, CO_2 0.72 = 100·45. See also *Scapolite,* p. 106.

MELACONITE, Min., p. 136; App. II., p. 38.—Vesuvius, *Scacchi,* Att. Accad. Napoli, vi., 1873 (Contrib. Min., ii., 12).

Melanophlogite. *A. v. Lasaulx,* J. Min., 1876, 250, 627; 1879, 513.

SULFURICIN, *Guyard,* Bull. Soc. Chim., II., xxii., 61, 1874. *Bresina,* Min. Mitth., 1876, 243.

Occurs in minute cubes, sometimes showing twinning striations. Cleavage cubic, nearly perfect (?) H. = 6·5–7. G. = 2·04. Color light brown or colorless. Lustre vitreous. Transparent. According to Bertrand the apparent cubic crystals are made up of six pyramids having a common vertex and with their bases coinciding with the cubic planes (Bull.

Soc. Min., iii., 160, 1880). Analyses: 1, v. Lasaulx (l. c.); 2, sulfuricin (see below), Guyard (l. c.):

	SiO_2	SO_3	H_2O	Al_2O_3	Fe_2O_3	SrO	MgO	CaO	
1. *Melanophlogite.*	86·29	7·2	2·86	0·7		2·8	....	....	= 99·85, Lasaulx.
2. *Sulfuricin.*	80·38	6·80	6·10	0·43	8·57*	....	0·37	1·25,	S 4·10 = (108).

* Brezina suggests that it probably should be 0·57.

Melanophlogite turns finally black when heated B. B. (hence name from μέλας, *black*, and φλέγεσϑαι, *to be burned*). Occurs forming a drusy coating on sulphur, calcite, and celestite, from Girgenti, Sicily.

SULFURICIN, from Greece, is described as a white porous silica, having a sour taste and impregnated with sulphur; the analysis is given above. Melanophlogite does not give an acid reaction. [The possible relation of the two substances mentioned is remarked by Brezina (l. c.). In any case melanophlogite can hardly be regarded as an original mineral, but more probably as an impure form of silica owing its origin to some method of pseudomorphism. v. Lasaulx thinks it cannot be pseudomorphous after fluorite. The observations of Bertrand would not separate it from the so-called *pseudo-isometric* species.]

Melanosiderite. *J. P. Cooke*, Amer. Acad. Sci., x., 451, 1875.

Amorphous; compact. H. = 4·5. G. = 3·391. Lustre vitreous, inclining to resinous. Color black, with a tinge of red. Streak brownish to brick red. Subtranslucent. In the closed tube decrepitates and gives off water. Gelatinizes with hydrochloric acid. B. B. fuses at 4½ to a magnetic mass. Analysis, by W. H. Melville afforded: SiO_2 (½) 7·42, Fe_2O_3 75·13, Al_2O_3 4·34, H_2O (at 100°) 6·17, H_2O (above 100°) 7·68 = 100·74. Cooke writes the formula $[Fe_2]_4SiO_{14}, 6H_2O$, which requires: Fe_2O_3 79·21, SiO_2 7·42, H_2O 13·37 = 100. If the silica is an impurity the composition is exactly that of limonite, as the author remarks; this seems more probable than that it is a true silicate. Locality, Mineral Hill, Delaware Co., Penn. Named from μέλας and σίδηρος, in allusion to the black color.

Genth (Second Rep. Min. Pennsylvania, p. 216, 1876), suggests that melanosiderite is only a variety of an iron hydrate, probably a limonite; Cooke, however, regards it as a basic silicate on the ground of its vitreous lustre, fusibility, definite composition, and the fact that it gelatinizes with acids.

Melanotekite. *G. Lindström*, Œfv. Ak. Förh. Stockh., xxxv., 6, p. 53, 1880.

Massive. Cleavage in two directions, in one of these most distinct. H. = 6·5. G. = 5·73. Lustre metallic to resinous. Color black to blackish gray. Streak greenish gray. Opaque to translucent under the microscope. Dichroic, bottle green and red brown. Analyses: 1, after deducting 2·56 p. c. impurities; 2, after deducting 3·30 p. c.:

	SiO_2	Fe_2O_3	PbO	CuO	FeO	MnO	CaO	MgO	K_2O	Na_2O	
1.	17·32	23·18	55·26	0·20	0·75	0·69	0·02	0·59	0·24	0·54	BaO 0·11 (?) Cl 0·14, P_2O_5 0·07, ign. 0·93 = 100·04.
2.	17·22	22·81	58·42	....	....	0·57	....	0·33	0·18	0·33.	

The atomic ratio for R : $[R_2]$: Si = 2 : 1 : 2, and the empirical formula is $Pb_2[Fe_2]Si_2O_9$. B. B. fuses with intumescence to a black bead; with soda on charcoal gives a globule of lead and a lead coating. With borax reacts for iron, but on strong heating in R. F. becomes on cooling black and opaque (reduced lead), with salt of phosphorus gives a skeleton of silica. Decomposed by nitric acid.

Occurs with native lead, intimately mixed with magnetite and yellow garnet at Långban in Wermland, Sweden. This locality has furnished two other lead silicates, hyalotekite and ganomalite (q. v.). Named in allusion to the related hyalotekite, from μέλας, *black*, and τήκειν, *to melt*. Lindström calls attention to the fact that of the two possible formulas for kentrolite proposed by Damour and vom Rath (see p. 65), the second corresponds exactly to the above composition of melanotekite, viz.: $Pb_2[Mn_2]Si_2O_9$, which establishes an interesting relation between the two minerals.

Melanothallite. *A. Scacchi*, copper chloride from the eruption of Vesuvius in 1870. Att. Accad. Napoli. (Bull. Soc. Min., i., 138).

Melanterite, Min., p. 646.—Cryst., and anal., Idria, *v. Zepharovich*, Ber. Ak. Wien, lxxix., 183, 1879.

A variety of melanterite containing a little manganese is called **luckite** by *Carnot* (Bull Soc. Min., ii., 168, 1879). In irregular striated prisms. Colorless or slightly bluish. Analysis: SO_3 26·3, FeO 21·7, MnO 1·9, MgO 0·2, CaO 0·5, H_2O [42·2], insol. 7·2 = 100. For this the formula is calculated $(Fe,Mn)SO_4 + 7aq$, with Fe : Mn = 11 : 1. From the silver mine "Lucky Boy," south of Salt Lake, near Butterfield Cañon, Utah.

Melinophane (**Meliphanite**), Min., p. 263; App. II., p. 38.—In tetragonal crystals with *I* and 1; *c* (vert.) = 0·6584, 1 ∧ 1 (terminal) = 122° 23′, Brevig, *Bertrand*, C. R. lxxxiii., 711, 1876.

The composition is discussed by *Rammelsberg* (ZS. G. Ges., xxviii., 61, 1876), who makes the formula $7R_2Si_2O_7 + 6NaF$, with R = Be : Ca = 1 : 1, and Na : K = 9 : 1; this requires: SiO_2 42·95, BeO 13·60, CaO 30·07, Na_2O 8·56, K_2O 1·44, F 5·83 = 102·45. It is undoubtedly distinct from leucophanite (q. v.).

Mellite, Min., p. 750.—Artificially produced, *Friedel* and *Balsohn*, Bull. Soc. Min., iv., 26, 1881.

Menaccanite, Min., p. 143, App. II., p. 38.—Cryst., tetartohedral, *v. Kokscharof*, Min. Russl., vi., 350, 1874. Binnenthal, tetartohedral, *Bücking*, Z. Kryst., i., 576, 1877; ii. 416, 1878. *Sadebeck*, Pogg. Ann., clvi., 557, 1875; J. Min., 1878, 287. *Groth*, Min.-Samml. Strassburg, p. 76, 1878.

Comp. discussed, *Friedel* and *Guérin*, Ann. Ch. Phys., V., viii., 38, 1876.

From diamond fields, So. Africa, anal. containing 12 p. c. MgO (compare anal. 24, Min. p. 144), *Cohen*, J. Min., 1877, 695. Egersund, Norway, *Tamm*, Geol. För. Förh., ii., 46, 1874.

A partially altered variety of menaccanite has been called **hydroilmenite** by *C. W. Blomstrand* (Minnesskrift Fys. Sällsk., Lund, 1878, p. 4). It forms thin (1–6 mm curved plates with tolerably distinct rhombohedral cleavage (*R* ∧ *R* = 86°–87°), and basal less so. G. = 4·066–4·136. Color iron black. Streak dark gray. Lustre metallic. Not magnetic. Analyses:

		TiO_2	SiO_2	Fe_2O_3	FeO	MnO	CaO	MgO	H_2O	
· 1.	(⅔)	60·80*	undet.	18·83†	15.75†	3·28	0·42	....	1·75.	
2.	(⅓)	54·23	1·40	14·99	21·91	6·34	0·45	0·19	1·33	= 100·84.

* With SiO_2? † The correctness of this separation is questioned.

The mineral decomposes readily, and finally becomes coated with a yellowish white crust consisting essentially of TiO_2. Probably altered from normal menaccanite by the assumption of water. From Småland, Sweden.

Mendozite, Min., p. 653.—Anal., Punta de Belen, Argentine Repub. (Schickendantz), *Brackebusch*, Min. Argentin., 75, 1879.

Meneghinite, Min., p. 105; App. II., p. 38.—Anal. (by Martini and Funaro), Bottino, Italy, *D'Achiardi*, Att. Soc. Tosc., ii., 116, 1876.

Meroxene.—See *Mica Group*, p. 77.

Mesolite, Min., p. 430; App. II., p. 38.—Lüdecke (J. Min., 1881, ii., 1), makes the crystals from Iceland monoclinic. An analysis by Schmid (Pogg. Ann., cxlii., 118), gave: SiO_2 46·58, Al_2O_3 27·57, CaO 9·11, MgO 0·08, Na_2O 3·64, H_2O 12·94, which corresponds very closely to the formula accepted by Rammelsberg, $\left\{\begin{matrix} Na_2Al_2Si_3O_{10} + 2aq. \\ 2(CaAl_2Si_3O_{10} + 3aq. \end{matrix}\right\}$ Lüdecke also refers here the monoclinic mesolite of Credner from the Pflasterkaute, which gave him: SiO_2 48·83, Al_2O_3 29·04, CaO 7·84, Na_2O 7·80, H_2O 11·75. See also *Scolecite*, p. 107.

Metacinnabarite, App. I., p. 10.—See *Onofrite*, p. 86.

METAXOITE (Chonicrite) Min., p. 494.—*Wiik* (J. Min., 1876, 204, *Kenngott*, ib., p. 517).

MEYMACITE.—App. II., p. 88.

MIARGYRITE, Min., p. 88.—Cryst., Bräunsdorf, *Weisbach*, Z. Kryst., ii., 55, 1877; *Groth*, Min.-Samml. Strassburg, p. 59, 1878.

Analyses by L. Sipöcz (Min. Mitth., 1877, 218), 1, miargyrite from Felsöbanya; 2, kenngottite from Felsöbanya; 3, by Jenkins (J. Min., 1880, ii., 109), hypargyrite from Andreasberg.

		S	Sb	Ag	Pb	Cu	Fe		
1.	G. = 5·298 (½)	21·80	40·68	32·77	4·01	0·51	0·19		= 99·96.
2. Kenngottite,	G. = 5·337	20·66	39·46	35·28	1·76	0·50	0·25		= 97·91.
3. Hypargyrite,	(½)	21·35	41·07	37·40	....	....	....	As 0·79	= 100·61.

These correspond to the accepted formula $AgSbS_2 = Ag_2S, Sb_2S_3$, and prove that kenngottite and hypargyrite are, as supposed, identical with miargyrite, the former containing a little lead. Weisbach had previously shown that hypargyrite agreed in form and physical characters with miargyrite (Z. Kryst., ii., 63, 1877). An analysis by *Andreasch* of miargyrite from Przibram gave S 21·68, Sb 41·15, Ag 36·71, Fe tr. = 99·54, both lead and copper being absent (Min. Petr. Mitth., iv., 185, 1881).

See also *Alaskaite*, p. 3.

MICA GROUP, Min., p. 301, et seq.; App. II., p. 39.—The optical investigations of Tschermak (Ber. Ak. Wien, lxxvi., 97, 1877; or Z. Kryst., ii., 14), have shown that all the micas are to be referred to the *monoclinic system*, the axis of elasticity being inclined a few degrees to the normal to the plane of cleavage. The exhaustive morphological study of *von Kokscharof* (Mem. Acad. St. Pet., VII., xxiv.; see also Min. Russl., vii., 167, 177, 222, 225; viii, 1) finally led him to a conclusion not at variance with this, although he shows that the angles alone do not require the assumption of any obliquity. The results of *Bauer* (Ber. Ak. Berlin, 1877, 684; or Min. Petr. Mitth., i., 14, 1878) confirm those of Tschermak; he has also determined the indices of refraction of muscovite, by a method based upon relations (established by Neumann) between the optical axes of elasticity and the distances, measured in the axial plane, between the dark rings of the interference figures.

Measurements of elasticity, *Coromilas*, Inaug. Diss. Tübingen, 1877 (Z. Kryst., i., 411). On the figures produced by etching, *Baumhauer*, Z. Kryst., iii., 113, 1878. *Wiik*, Œfv. Finsk. Vet. Soc., xxii., 1880.

Association of muscovite and biotite (meroxene) in parallel position, from Middletown, Conn., *Hawes* (anal. of the biotite ½: SiO_2 35·61, Al_2O_3 20·03, Fe_2O_3 0·13, FeO 21·85, MnO 1·19, MgO 5·23, K_2O 9·69, Na_2O 0·52, Li_2O 0·93, TiO_2 1·46, F 0·76, Cl tr., H_2O 1·87 = 99·27, cf. haughtonite below), Am. J. Sc., III., xi., 431, 1876; *v. Lasaulx*, J. Min., 1878, 630.

Tschermak (l. c. and Ber. Ak. Wien, lxxviii., 5, 1878, or Z. Kryst., iii., 122) divides the species of the mica group as follows:

	I.	II.
Biotites:	Anomite;	Meroxene, Lepidomelane.
Phlogopites:		Phlogopite, Zinnwaldite.
Muscovites:	Lepidolite. Muscovite. Paragonite.	
Margarites:	Margarite.	

In the first group (I) are included all the micas in which the optic-axial plane is perpendicular to the plane of symmetry; the second group (II) includes those in which it is parallel to the plane of symmetry. For the crystallographic relations of the different species reference must be made to the original paper. The chemical relations reached by Tschermak are based for the most part on a series of new analyses, very carefully made, to avoid errors fallen into by earlier analysts; these are quoted beyond.

Tschermak, on optical grounds (see above), divides biotite into ANOMITE (from ἀνομός, *contrary to law*) and MEROXENE (Breithaupt's name for the Vesuvian biotite, see Min., p. 307). *Anomite* is represented by the mica occurring with diopside in granular calcite, at

Lake Baikal, and that from Greenwood Furnace, N. Y. Its composition, according to Tschermak's view, is expressed by isomorphous mixtures of $H_2K_4Al_6Si_6O_{24}$ (see muscovite, below), and $Mg_{12}Si_6O_{12}$ (a hypothetical polymere of chrysolite), in the relation of 1 : 1, or 2 : 1, or intermediate ratios. *Meroxene* is represented by the Vesuvian magnesian mica: composition $H_3K_3Al_6Si_6O_{24}$, and $Mg_{12}Si_6O_{12}$ in the ratio of 1 : 1, of 2 : 1, or intermediate ratios. *Lepidomelane* has the composition $H_4K_2Al_6Si_6O_{24}$, and $Mg_{12}Si_6O_{12}$, with, however, varying amounts of the iron compound $H_4K_2Fe_6Si_6O_{24}$. [In this group would belong the haughtonite of Heddle, and siderophyllite of Lewis (see below), varieties characterized by the replacement to large extent, of Mg by Fe.]

Phlogopite has the composition: $K_6Al_6Si_6O_{24}$, $H_6Si_{10}O_{24}$, and $Mg_{12}Si_6O_{24}$, often in the relation 3 : 1 : 4; generally also with $F_{24}Si_{10}O_6$ in the place of the second compound. *Zinnwaldite* has the composition: $K_6Al_6Si_6O_{24}$ (or $Li_6Al_6Si_6O_{24}$), $Fe_{12}Si_6O_{24}$, and $F_{24}O_6Si_{10}$ (or the corresponding hydrogen compound), in the relation of 10 : 2 : 3.

The muscovites include lepidolite, muscovite, and paragonite. *Lepidolite* has the composition: $3K_6Al_6Si_6O_{24} + Si_{10}O_6F_{24}$, with the first replaced one-half or more by the corresponding lithium compound, and the second by the corresponding hydrogen compound (see also Min. Petr. Mitth., ii., 94, 1879). *Muscovite* (including margarodite): $K_6Al_6Si_6O_{24}$, with the potassium compound replaced in part by the corresponding hydrogen compound $H_6Al_6Si_6O_{24}$; the commonest formula is $H_4K_2Al_6Si_6O_{24}$. In certain muscovites, for which the name PHENGITE is proposed, the composition is explained as a combination of $H_4K_2Al_6Si_6O_{24}$, and $H_6Si_{10}O_{24}$, in the ratio of 3 : 1; these varieties approach to lepidolite. *Paragonite* (incl. cossaite), composition: $H_4Na_2Al_6Si_6O_{24}$.

Margarite, composition: $H_4Ca_2Al_8Si_4O_{24}$; related to the clintonite group, see p. 28.

[For the many important details of the crystallographic relations, and, too, the discussion upon which the above conclusions as to the composition are based, reference must be made to the original articles.]

Analyses employed in the above discussion: 1, by John, Lake Baikal; 2. by P. v. Hamm. Greenwood Furnace, G. = 2·816; 3, by A. Zellner, Tschebarkul, Siberia, G. = 3·004; 4, by J. Rumpf, Morawitza; 5, by Berwerth, Vesuvius, G. = 2·86; 6, E. Ludwig, with pargasite in granular limestone, G. = 2·867; 7, by E. Neminar, Penneville, G. = 2·779; 8, by A. Poppovits, Ratnapura, Ceylon, G. = 2·742; 9, by Berwerth, Edwards, N. Y.; 10, by Berwerth, Zinnwald; 11, by Berwerth, Paris, Me., G. = 2·855; 12, by Berwerth, Rozena, G. = 2·839; 13, by S. Blau, Bengal, G. = 2·831; 14, by L. Sipöcz, East Indies, G. = 2·8[illegible]; 15, by L. Sipöcz, Rothenkopf in the Zillerthal, G. = 2·892; 16, by Löbisch, Soboth in Steiermark.

Rammelsberg has also published (Wied. Ann., ix., 113, 302, 1880; also vii., 136, 1879) a recent investigation of the chemical composition of the species of the mica group, including a considerable number of new analyses. He concludes that the micas are in part unisilicates, in part compounds of unisilicates and bisilicates; he also assumes the isomorphism between these, as well as between similar silicates of metals of the $\overset{\text{i}}{R}$, $\overset{\text{ii}}{R}$, $[\overset{\text{vi}}{R}_2]$ series respectively. He adopts a chemical classification, as follows:

1. ALKALI micas: A. *Sodium* mica (paragonite) formula $R_2[Al_2]Si_2O_8$ (unisilicate). B. *Potassium* mica (muscovite), including (1) unisilicates, $R_2[Al_2]Si_2O_8$, with sometimes $(Mg,Fe)_2SiO_4$; (2) compounds of unisilicates and bisilicates in the ratio of 1 : 3, thus $R_{10}R[R_2]$ $Si_{12}O_{48}$ (anal. 1, 2, 3), or in the ratio of 1 : 1, thus: $\overset{\text{i}}{R}_6Si_2O_7 = \overset{\text{i}}{R}_2SiO_3 + \overset{\text{i}}{R}_4SiO_4$, or more

specially in part, $R_{14}R_2[R_2]_6Si_{18}O_{63}$. C. *Lithium* mica (lepidolite, anal. 4, 5, 6a, 6b): compounds of unisilicates and bisilicates in the ratio of 1:3, thus: $R_{10}Si_4O_{13} = 3R_2SiO_3 + R_4SiO_4$; or more specially $R_{16}[R_2]_5Si_{16}O_{52}$ (Rozena and Paris), and $R_{14}[R_2]_6Si_{20}O_{65}$ (Juschakowa).

2. The MAGNESIUM mica (biotite pt., anal. 7, 8, 9) is a compound of bisilicates and unisilicates in the ratio of 1:3, thus: $R_{14}R_{35}[R_2]_7Si_{36}O_{135}$.

3. The IRON-MAGNESIUM mica (biotite pt.) and IRON mica (lepidomelane), includes five series, having the following formulas: (1) $R_2R_4[R_2]Si_4O_{16} = R_4SiO_4 + 4R_2SiO_4 + [R_2]_2Si_3O_{12}$ (anal. 10, 11). (2) $R_4R_6[R_2]_2Si_7O_{28} = R_4SiO_4 + 3R_2SiO_4 + [R_2]_2Si_3O_{12}$ (anal. 12, 13, 14, 15). (3) $R_2R_2[R_2]Si_3O_{12} = R_4SiO_4 + 2R_2SiO_4 + [R_2]_2Si_3O_{12}$ (anal. 16, 17). (4) $R_2R_3[R_2]_2Si_5O_{20} = R_4SiO_4 + 3R_2SiO_4 + 2[R_2]_2Si_3O_{12}$ (anal. 18, 19). (5) $R_6R_3[R_2]_4Si_9O_{36} = 3R_4SiO_4 + 2R_2SiO_4 + 4[R_2]_2Si_3O_{12}$. To this group are appended several which do not admit of being classified.

4. The LITHIUM-IRON mica of Zinnwald (zinnwaldite, anal. 20) is regarded as a compound of bisilicate and unisilicate in the ratio of 2:1, thus: $R_8Si_3O_{10} = 2R_2SiO_3 + R_4SiO_4$; more specially $R_{10}R_4[R_2]_5Si_{18}O_{60}$, or $R_{12}R_4[R_2]_6Si_{21}O_{70}$, according to the ratio of the different elements.

5. The BARIUM mica (œllacherite, anal. 21) is a unisilicate, with the special formula: $R_8R_2[R_2]_4Si_9O_{36} = 2R_4SiO_4 + R_2SiO_4 + 2[R_2]_2Si_3O_{12}$.

Analyses by Rammelsberg (see also Ber. Ak. Berlin, 1878, 616; 1879, 248, 833; ZS. G. Ges., xxxi., 676, 1879):

	SiO_2	Al_2O_3	Fe_2O_3	Mn_2O_3	FeO	MnO	MgO	K_2O	Na_2O	Li_2O	H_2O*	F

HAUGHTONITE of *Heddle* (Min. Mag., iii., 72, 1879) is a variety of biotite, in which the magnesium is largely replaced by iron. G. = 2·96–3·13. Fuses with difficulty to a black magnetic globule. Color dark brown to jet black. Small axial angle. Occurs mostly in granitic and gneissoid rocks, also in diorite, at various Scottish localities, as below. Analyses by Heddle: 1, from hornblendic gneiss of Roneval; 2, from the hill of Capval; 3, Nishibost; 4, from the shore of Loch-na-Muilne; 5, Fionaven in Sutherland; 6, Ben Stack; 7, Rispond; 8, Clach-an-Eoin; 9, Kinnaird's Head, Aberdeenshire; 10, Cove near Aberdeen; 11, Lairg, in Sutherland; 12, Portsoy in Banffshire.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	CaO	MgO	Na_2O	K_2O	H_2O

11.	35·56	16·69	1·88	18·04	0·69	2·72	8·47	0·11	9·90	5·71	= 99·77.
12. G. 3·07	34·08	17·34	3·61	18·70	0·38	3·23	10·54	1·19	6·78	4·05	= 99·90.

Other analyses by Heddle are given in Min. Mag., iv., 221 et seq., 1881; and the same variety has been repeatedly analyzed previously (see above).

A mica closely related to the above (a biotite containing only Fe) has been called SIDEROPHYLLITE by *H. C. Lewis* (Proc. Ac. Nat. Sc. Philad., 1880, 254). H. = 3·2. G. = 3·1. Color black; by transmitted light chrome green. Brittle. Axial angle about 10°. An analysis gave (⅔): SiO_2 36·68, Al_2O_3 20·41, Fe_2O_3 1·55, FeO 25·50, MnO 2·10, MgO 1·14, CaO 0·81, Na_2O 1·09, Li_2O 0·37, K_2O 9·20, H_2O 1·01 = 99·86. This corresponds to $R_2[R]$ Si_3O_{12}. Fuses with intumescence at 2·5 to a black glass. Soluble in HCl and H_2SO_4 with separation of silica. From near Pike's Peak, Colorado.

EUCHLORITE of *C. U. Shepard* is shown by *Pisani* (C. R., lxxxiii., 167, 1876) to be ordinary biotite. From Chester, Mass. H. = 2·5. G. = 2·84. Color dark green. Lustre on the cleavage face pearly. Axis negative. B. B. fusible with difficulty to a black enamel. Slowly soluble in concentrated HCl. An analysis gave Pisani: SiO_2 39·55, Al_2O_3 15·95, Fe_2O_3 7·80, MgO 22·25, K_2O,Na_2O 10·35, ign. 4·10 = 100.

MICARELL. *Wichmann* (ZS. G. Ges., xxvi., 701, 1874) uses this name (of Freiesleben) to designate the original mineral from which the so-called pinite from Stolpen, near Neustadt, has been derived. It is regarded as certain that it is not iolite nor tourmaline, but its true nature is doubtful.

Microcline. *Des Cloizeaux* (Ann. Ch. Phys., V., ix., 433, 1876) uses Breithaupt's name (see Min., p. 355) to designate a new feldspar species established by him: a triclinic potash feldspar.

Triclinic and near orthoclase in form, and in habit, twinning, etc., but $O \wedge i\text{-}\bar{i} = 90^\circ\ 16'$. Extinction direction makes an angle of 15° to 16° (orthoclase = 0°), with the edge $O \,/\, i\text{-}\bar{i}$. Polysynthetic twinning, giving rise to striations on *O*, sometimes observed. A basal section shows in polarized light a characteristic grating-like structure, due to the regular intergrowth of twin lamellæ; in these, orthoclase is often enclosed; irregular lines and bands of albite also often observed.

Composition $K_2\,[Al_2]\,Si_6O_{16}$, or that of orthoclase; an analysis of pure white microcline from Magnet Cove, Arkansas, gave Pisani: SiO_2 64·30, Al_2O_3 19·70, Fe_2O_3 0·74, K_2O 15·60, Na_2O 0·48, ign. 0·35 = 101·17. G. = 2·54.

A large part of the potash feldspar, previously called orthoclase, is in fact microcline. Here belong the *chesterlite* from Chester, Penn., the beautiful amazonstone of Pike's Peak, Colorado (the color due to an organic salt of iron, according to König, Proc. Ac. Nat. Sc. Philad., 1876, 156), as also that of other localities; also feldspar from Mineral Hill, Penn., Leverett (not Everett), Mass., and many foreign localities. It is obtained in large quantities at Branchville, Conn., some single cleavage surfaces having a length of 10 feet; also observed at the same locality pseudomorph after spodumene. The perthite of Canada is in part microcline (J. Min., 1879, 389).

MICROLITE, Min., p. 513; App. II., p. 39.—Described by *Nordenskiöld* (Geol. För. Förh., iii., 282, 1877). In small brilliant isometric octahedrons with dodecahedral planes. Color light grayish yellow to blackish brown. Translucent to semi-translucent. H. = 5·5–6. G. = 5·25. An approximate analysis gave: Ta_2O_5,Cb_2O_5 77·3, SnO_2 0·8, CaO 11·7, MnO (FeO tr.) 7·7, MgO 1·8 = 99·3. Formula $(Ca,Mn,Mg)_2Ta_2O_7$, which requires: Ta_2O_5 78·82, MnO 7·69, CaO 11·69, MgO 1·80 = 100. B. B. infusible. Occurs with red and green tourmaline, petalite, spodumene, etc., in pegmatite, at Utö, Sweden.

Occurs at Branchville, Conn., *Brush* and *Dana*, Am. J. Sc., III., xvi., 34, 1878.

Described by *F. P. Dunnington* (Am. Chem. Journ., iii., 130, 1881) as occurring at the mica mines in Amelia Co., Virginia. In single crystals from $\frac{1}{16}$ in. to $\frac{1}{4}$ in., with *O*, *i*, and *3-3*; also in large (up to 4 lbs.) imperfect crystals. H. = 6. G. = 5·656. Lustre glistening resinous. Color wax yellow to brown. Streak pale ochreous yellow. Subtranslucent. Fracture conchoidal. Brittle. An analysis gave: Ta_2O_5 68·43, Cb_2O_5 7·74, WO_3 0·30, SnO_2 1·05, CaO 11·80, MgO 1·01, BeO 0·34, U_2O_3 1·59, Y_2O_3 0·23, Ce_2O_3 (Di_2O_3) 0·17, Al_2O_3 0·13, Fe_2O_3 0·29, Na_2O 2·86, K_2O 0·29, F 2·85, H_2O 1·17 = 100·25, deduct O replaced by F 1·20 = 99·05. The probable formula deduced is $3(Ca_2Ta_2O_7) + CbOF_3$. In the closed tube decrepitates and gives off water. B. B. infusible, glows momentarily, colors the flame reddish yellow, and on cooling is dull pale yellow. Not attacked by strong HCl, slowly decomposed by H_2SO_4 and by fusion with caustic potash; readily decomposed by fusion with acid potassium sulphate. Associated with the true microlite is monazite in large masses (up to 8 lbs.). It was at first called altered microlite (priv. contrib., W. M. Fontaine).

A mineral related to microlite, from Haddam, Conn., is called HADDAMITE by *C. U. Shepard* (Am. J. Sc., II., l., 93, 1870; Min. Contr., 1877). What its true character is, if it be a distinct species, has not been determined.

MICROLITES.—App. II., p. 39.

MICROSOMMITE, App. II., p. 39.—Analyses 1, 2 by *Scacchi* (Rend. Accad. Sc. Napoli, April, 1876); 3, 4 by *Rauff* (Z. Kryst., ii., 468, 1878). 1, large crystals, Monte Somma, 2, microscopic crystals from bombs thrown out in April, 1872; 3, 4, crystals from Mt. Somma; 3, colorless; 4, yellow.

	SiO_2	Al_2O_3	CaO	Na_2O	K_2O	Cl	SO_3	CO_2	
1. ($\frac{2}{2}$)	32·21	29·22	12·60	10 14	6·79	6·71	4·43	....	= 102·15, deduct O replaced by Cl 1·51 = 100·59.
2. ($\frac{3}{3}$)	31·42	30·34	10·98	9·87	7·90	7·82	5·26	....	= 103·04, deduct O 1·76 = 101·28.
3. ($\frac{3}{3}$)	32·21	28·37	10·59	11·30	7·14	7·09	3·86	1·55	S tr. = 102·11, deduct O 1·60 = 100·51.
4.	32·23	28·98*	10·36	11·01	7·11	6·25	4·11	1·26	S tr. = 102·01, deduct O 1·56 = 100·45.

* (Fe_2O_3 tr.)

The crystals examined by Rauff were large as compared with the original mineral. Scacchi describes prismatic crystals with *I*, *i*-2, *i*-$\frac{3}{2}$, 1, *O*; *c* (vert.) = 0·41834; 1 ∧ 1 (adj) = 124° 53½′, 1 ∧ *I* = 115° 47′; the form corresponds very closely to that of nephelite (*c* (vert.) = ·8390 = 2*c* (vert.) microsommite, Min., p. 327). Cleavage *I* perfect, *O* less distinct (as in nephelite). H. = 6. G. = 2·444 (Rauff), 2·42–2·53 (Scacchi). Lustre *I* brilliant silky. The formula calculated by Rauff is 2 [$(CaSO_4)$ + $3CaAl_2Si_2O_8$] + [4NaCl + $8Na_2Al_2Si_2O_8$] + [4NaCl + $8K_2Al_2Si_2O_8$], he also makes the rather improbable assumption that a portion of the Si is replaced by C (Si : C = 20 : 1), the formula then requires: SiO_2 32·68, CO_2 1·20, Al_2O_3 29·33, CaO 10·67, Na_2O 10·34, K_2O 6·72, SO_3 3·81, Cl 6·77 = 101·52, deduct O 1·52 = 100. Rauff also shows that the mineral from Mt. Somma called davyne is in part an altered microsommite. See also *Cancrinite*, p. 20.

Microschörlite, Microvermiculite.—See *Kaolinite*, p. 65.

MILARITE, App. I., p. 10; II., p. 39.—Crystals shown by *Des Cloizeaux* (J. Min., 1878, 42, 370), and also by *Tschermak* (Min. Mitth., 1877, 350), and *Bertrand* (Bull. Soc. Min., iv., 10, 1881), to be orthorhombic, the pseudo-hexagonal form being due to twinning similar to that of aragonite, witherite, etc. An analysis by *Ludwig* (Min. Mitth., 1877, 349), gave:

	SiO_2	Al_2O_3	CaO	MgO	K_2O	Na_2O	H_2O	
($\frac{2}{3}$)	71·81	10·67	11·65	tr.	4·86	tr.	1·36	= 100·35.

The formula given by Ludwig is $HKCa_2Al_2Si_{12}O_{30}$, which requires: SiO_2 72·66, Al_2O_3 10·39, CaO 11·30, K_2O 4·74, H_2O 0·91 = 100.

Kuschel (J. Min., 1877, 926), repeats the statement of Frenzel (J. Min., 1873, 797; App. II., p. 39), that the mineral is found in Val Giuf, not Val Milar, and adds that it ought on this account to be called *giufite*.

MILLERITE, Min., p. 56; App. II., p. 40.—Found at Micheroux, Belgium, *Firket*, Bull. Soc. Geol. Belg., v., 120, 1878; vi., 152, 1879.

MIMETITE.—Min., p. 537; App. II., p. 40.—Etching experiments by *Baumhauer* show mimetite to be pyramidal-hemihedral like apatite (J. Min., 1876, 411).

Bertrand (Bull. Soc. Min., iv., 36, 1881), has made the interesting observation that crystals of pure lead arsenate are biaxial (2*E* = 64°) and that as the percentage of P_2O_5 increases, this angle diminishes, and the pure lead phosphate is uniaxial. *Jannettaz* has obtained similar results (ib., p. 39), and *Jannettaz* and *Michel* (ib., p. 196), have accompanied a more detailed optical study by a series of analyses which add much to the completeness of the investigation.

Anal., Långban, Sweden, by Kiutaro Iwaya, quoted by *Lindgren*, Geol. För. Förh., v., 272, 1880. Mina Grande, Marqueza, Chili, *Domeyko*, 6th App., Min. Chili, p. 16, 1878.

Occurrence with vanadinite in Arizona, *Silliman*, Am. J. Sc., III., xxii., 202, 1881; *W. P. Blake*, Min. Sc. Press, Aug., 13, 1881.

See also *Hedyphane*, p. 56.

MIRABILITE, Min., p. 636.—Cryst., Aussee, Upper Austria, *v. Zepharovich*, Lotos, 1877. Anal., Province of Tarapaca, Peru, *Raimondi*, Min. Pérou, p. 288, 1878. Sicily, *Paterno*, Accad. Linc. Trans., III., iv., 22, 1879.

MIRIQUIDITE.—App. II., p. 40.

Mixite. *Schrauf*, Z. Kryst , iv., 277, 1879.
Crystalline to crypto-crystalline. As an incrustation on bismuth ochre, also in irregular particles, granular and rough or spherical, reniform, with partial concentric fibrous structure. The fibres are occasionally distinct six-sided prisms (125°), regarded as probably monoclinic or triclinic (extinction 6°–9° with prismatic edge). H. = 3–4. G. = 2·66. Color emerald to bluish green; streak somewhat lighter. Translucent to transparent (for fibres). Analysis:

	$\underbrace{As_2O_5,(P_2O_5)}$	Bi_2O_3	CuO	H_2O	FeO	CaO
(3)	30·45	13·07	43·21	11·07	1·52	0·83 = 100·15.

The formula calculated is $Cu_{20}Bi_2As_{10}H_{44}O_{70}$; this requires: As_2O_5 31·93, Bi_2O_3 12·99, CuO 44·08, H_2O 11·00 = 100. In dilute nitric acid the mineral is instantly covered with a layer of a brilliant white powder of bismuth arsenate, insoluble in the acid; the copper arsenate goes into solution. On ignition becomes blackish green. Occurs with bismuth ochre, bismutite, and torbernite in the Geistergang at Joachimsthal. Named in honor of Bergrath A. Mixa.

MOLYSITE, Min., p. 118.—Vesuvius, *Scacchi*, Att. Accad. Napoli, vi., 1873 (Contrib. Min., ii., 43).

MOLYBDENITE, Min., p. 32.—Biellese, Italy, *Cossa*, Accad. Linc. Trans., III., i., 206, 187 Groth suggests that the species may be orthorhombic, Min.-Samml. Strassburg, p. [illegible] 1878.

MONAZITE, Min., p. 539; App. II., p. 40.—Cryst., Tavetsch, Switzerland (turnerite), vom *Rath*, J. Min., 1876, 393. Binnenthal (turnerite), also optical investigation, *Trechmann*, J. Min., 1876, 593. *Von Kokscharof*, Min. Russl., vi., 387. Ilmen Mts., *von Jeremejew*, Verh. Min. Ges. St. Pet., II., xii., 287. *Seligmann*, Corr. Bl. Nat. Ver. Bonn, xxxvii., 131, 1880. Optical examination, *Des Cloizeaux*, Bull. Soc. Min., iv., 57, 1881.
Analysis, Arendal, G. = 5·174 : P_2O_5 29·92, Ce_2O_3 28·82, La_2O_3 + Di_2O_3 40·79 = 99·53, formula: $[R_2]P_2O_8$, with $[R_2] = Ce_2:(La_2Di_2) = 2:3$; this requires: P_2O_5 30·28, Ce_2O_3 27·72, La_2O_3, Di_2O_3 42·00 = 100 ; contains no thorium nor zirconium, *Rammelsberg*, ZS. G. Ges. xxix., 79, 1877. Analysis of turnerite (on ·013 gr.): P_2O_5 28·4, Ce_2O_3 (La_2O_3, Di_2O_3) 68·0 = 96·4, *Pisani*, C. R., lxxxiv., 462, 1877.
Absorption bands (Ce, La, Di) in spectrum (turnerite), *Cossa*, Accad. Linc. Mem., III. 80, 1878.
Occurrence with zircon in gold sands of Ivalo, Finnish Lapmark, *Nordenskiöld*, Geol. För. Förh., ii., 223, 1874. Occurrence in brilliant highly modified crystals, at Milholland's mill, Alexander Co., N. C., also at other localities in North Carolina, *Hidden*, Am. J. Sc. III., xxii., 21, 1881. From the pegmatite vein at Ånnerod, near Moss, Norway, *W. C. Brögger*, Geol. För. Förh., v., 350, 1881. From Nil-St.-Vincent, *Renard*, Bull. Soc. Géol. Belg., III., ii., 128, 1881. See *Microlite*, p. 80.

MONIMOLITE, p. 546; App. II., p. 40.—Occurs at Långban, Wermland, Sweden, *Nordenskiöld*, Geol. För. Förh., iii., 379, 1877.

MONTEBRASITE.—See *Amblygonite*, p. 5.

MONTICELLITE.—Min., p. 255; App. II., p. 40.

MONTMORILLONITE, Min., p. 459.—Anal., Macskamezö, near Podu ruoj, Transylvania, *Helmhacker*, Min. Petr. Mitth., ii., 251, 1879. Great Retallack mine, Cornwall, *Collins*, Min. Mag., ii., 92, 1878. Branchville, Conn., anal. by H. L. Wells, described by *Brush* and *Dana*, Am. J. Sc., III., xx., 283, 1880.

MONZONITE.—App. I., p. 11.

MORDENITE, Min., p. 446.—A partially altered mordenite is called STEELEITE, *How* (Min. Mag., ii., 134, Sept., 1878). Found as red or reddish pink, or chalk-white, balls, varying in size from one to two and a half inches in diameter, imbedded in a red clay in cavities in trap. Also in other forms, closely associated with stilbite. In part soft and chalk-like; in part hard and unaltered. Gelatinizes with acids. Locality Cape Split, 13 miles west of Cape Blomidon, N. S.

MOSANDRITE, Min., p. 295.—Shown to be in fact monoclinic, *Brögger*, Z. Kryst., ii., 275, 1878.

Mottramite. *H. E. Roscoe*, Proc. Roy. Soc., xxv., 111, 1876.
In thin crystalline incrustations, occasionally in distinct, minute crystals, also compact. H. = 3. G. = 5·894. Lustre resinous. Color velvety black; in thin sections yellow. Streak yellow. Translucent. Analyses, Roscoe (l. c.): 1; 2, after deducting impurities:

	V_2O_5	PbO	CuO	FeO, ZnO, MnO	MgO	CaO	H_2O
1. (⅔)	17·14	50·97	19·10	2·52	0·26	2·13	3·63, hygroscopic water 0·22, SiO_2 [1·06 = 97·03.
2.	18·87	56·12	21·02	....	....	....	3·99 = 100.

The formula suggested is $(Pb,Cu)_3V_2O_8 + 2(Cu,Pb)H_2O_2$, which requires: V_2O_5 18·74, PbO 57·18, CuO 20·39, H_2O 3·69 = 100. The composition is thus analogous to dihydrite and erinite [but doubtful, owing to the imperfect analysis; note the loss of 3 p. c.]. Occurs on the Keuper Sandstone, at Alderley Edge, and at Mottram St. Andrews, Cheshire, England.

Muckite. *J. von Schröckinger*, Verh. G. Reichs., 1878, 387.
A resin from the coal beds at Neudorf, Moravia, disseminated in minute particles, and in small bands. Color opaque yellow, or light brownish yellow, and transparent to translucent. H. = 1–2. G. = 1·0025. An analysis by Dietrich gave: (¼) C 79·22, H 9·57, O 11·21, corresponding to $C_{20}H_{28}O_2$. Fuses between 290° and 310°. In alcohol, 14 p. c., dissolves; in ether, 40 p. c., both leaving a yellowish-brown residue. Other similar experiments prove that the substance is a mechanical mixture of different resins.

MUSCOVITE.—See *Mica Group*, p. 77.

MYSORIN, Min., p. 715.—From the Nellore district, India. Examined by *F. R. Mallet*, and shown to be essentially an impure malachite, with 9·02 H_2O; it contained as impurities, calcite, chrysocolla, barite, chalcocite, iron sesquioxide, Rec. Geol. Surv. India, xii., 166, 1879.

NADORITE.—App. I., p. 11.

NÆSUMITE.—App. I., p. 11.

NAGYAGITE, Min., p. 82.—*Schrauf* (Z. Kryst., ii., 239, 1878) shows that the crystalline system is not tetragonal, but either orthorhombic or perhaps still lower in symmetry. Fletcher observes the development of the planes to be in accordance with orthorhombic symmetry (Phil. Mag., V., ix., 188, 1880).

NAMAQUALITE.—App. I., p. 11.

NANTOKITE.—App. I., p. 11; II., p. 40.

NATROLITE, Min., p. 426; App. II., p. 41.—**Cryst.**, Salesel, Bohemia, *Seligmann*, Z. Kryst., i., 338, 1877. Auvergne, *Lüdecke*, Z. gesammt. Nat., III., iv., 145, 1879. Arö, Norway, *Brögger*, Z. Kryst., iii., 478, 487, 1879.

According to *Lüdecke* (J. Min., 1881, ii., 7), the natrolite from Aussig and Salesel must, on optical grounds, be referred to the monoclinic system. See Lüdecke's memoir also, on the relation of natrolite to scolecite and mesolite.

Pyro-electrical characters, *Hankel*, Wied. Ann., vi., 55, 1879.

Analyses, Kuchelbad, near Prague, *Preis* and *Vrba*, Ber. Ges. Böhm., 1879, 469.

NATRON, Min., p. 705.—Analyses of related salts quoted by *Brackebusch*, Min. Argentina, p. 70, 1879.

NEFIEDIEFFITE.—App. II., p. 41.

Neochrysolite.—See *Chrysolite*, p. 27.

Neociano—NEOCYANITE. *Scacchi*, Rend. Accad. Napoli, Jan., 1881.

In extremely minute tabular monoclinic crystals. Color blue. Supposed to be an anhydrous copper silicate. B. B. fuses to a black glass. Easily decomposed by acids, with the separation of pulverulent silica. From fumaroles at Vesuvius, formed by sublimation, together with three other substances. One of these forms a white granular mass, G. = 2·287, probably silica. A second is a white asbestos-like material, containing lime; difficultly fusible, and decomposed only in boiling acid. The other forms yellowish-brown crystals in six-sided rhombic plates; insoluble in acid. [Needs further examination.]

NEPHELITE, Min., p. 327; App. II., p. 41.—**Cryst.** (*O* ∧ 1 = 136° 9′ 20″), Albani Mts., near Rome, *Strüver*, Z. Kryst., i., 240, 1877. Island of Laaven, Langesundfiord, Norway (*elæolite* in elæolite-syenite, *O* ∧ 1 = 136°), *Klein*, J. Min., 1879, 534.

Made artificially, *Fouqué* and *Lévy*, C. R., lxxxvii., 961, 1878.

Alteration products in nephelite rocks, *v. Eckenbrecher*, Min. Petr. Mitth., iii., 1, 1880.

Analyses, Ditró, Transylvania (elæolite), *A. Koch*, Min. Mitth., 1877, 335. Vesuvius, G. = 2·600–2·609, *Rammelsberg*, ZS. G. Ges., xxix., 78, 1877. Vesuvius, *Rauff*, Z. Kryst., ii., 445 et seq., 1878. In foyaite of the Sierra de Monchique, Southern Portugal, *Schaf-ner*, Q. J. G. Soc., 1879, 46, quoted by van Wervecke, J. Min., 1880, ii., 143. Ditró, Transylvania (elæolite), *A. Koch* (anal. by Franz Koch), J. Min., Beil.-Bd., i., 143, 1880.

The chemical composition of nephelite is discussed by Rammelsberg (l. c.) and Rauff (l. c.). The former deduces the formula: $\overset{\prime}{R}_6[Al_2]_3Si_7O_{26} = 5(Na_2[Al_2]Si_2O_8) + K_2Al_2Si_4O_{12}$; the latter obtains: $\dot{R}_8[Al_2]_4Si_9O_{34} = 7R_2[Al_2]Si_2O_8 + R_2[Al_2]Si_4O_{12}$. Rauff seems to prove, contrary to Rammelsberg, that the pure mineral contains some CaO (1·32–1·76 p. c.), and perhaps also a little basic water (0·12–0·14 p. c.) and a trace of chlorine. Rauff also discusses the relation of nephelite (and elæolite) to cancrinite and microsommite.

NEPHRITE, Min., p. 233, et al.; App. II., p. 41.—**Analyses** of specimens from New Zealand, *Berwerth*, Ber. Ak. Wien, lxxx., 102, 1879 (see also J. Min., 1880, i., 170 (ref.), and 1881, i., 99). Several analyses quoted by Fischer, Z. Kryst., iii., 592, 1879. Siberia (= tremolite), *Jannettaz* and *Michel*, Bull. Soc. Min., iv., 178, 1881.

For a general and detailed discussion of nephrite and jadeite, in all their relations, but especially archæological, see the works of Fischer, whose titles are given in the Bibliography (see Introduction); noticed in J. Min., 1876, 218, and 1880, ii., 319 (ref.); also ib., 1880, ii., 113. See also Annual Rep. Smithsonian Inst., 1876, 402.

Neudorfite. *J. von Schröckinger*, Verh. G. Reichs., 1878, 387.

A resin occurring in a coal bed at Neudorf, Moravia. Color pale yellow. Lustre waxy. Fracture conchoidal. G. = 1·045–1·060. An analysis by Dietrich gave: C 78·04, H 9·84, O 11·98, N 0·14, corresponding to $C_{18}H_{28}O_2$ = C 78·26, H 10·14, O 11·60 = 100. Fuses at 280°. Dissolves in ether, leaving a whitish-yellow resinous powder.

Newberyite. *G. vom Rath*, Ber. nied. Ges. Bonn, Jan. 13, 1879; Bull. Soc. Min., ii., 81, 1879.

Orthorhombic; axes, *c* (vert.) : $\breve{b}$: $\bar{a}$ = 0·9300 : 1 : 0·9435. Observed planes: i-ĭ, i-ī, *O*, ½-ĭ, 2-ĭ, 1. Angles: *O* ∧ ½-ĭ = 153° 46′, O ∧ 1 = 126° 26′, 1 ∧ 1 = 108° 22′. In large (1 sq.

in.) tabular crystals. Cleavage *i-ī*, perfect; basal imperfect (v. Rath). Optic axes in the brachydiagonal section. Acute bisectrix (+) normal to the base. Dispersion considerable $\rho < \upsilon$. $2H_a = 44° 46'$ (red), $2H_o = 142° 8'$ (red), Des Cloizeaux.

Analysis, MacIvor:

P_2O_5	MgO (MnO tr.)	H_2O		
41·25	[23·02]	35·73	=	100

Formula: $Mg_2H_2P_2O_8 + 6aq = P_2O_5$ 40·80, MgO 22·99, H_2O 36·21 = 100. Loses its water about 110° C. Easily soluble in acids. From the guano in the Skipton Caves, Victoria; first recognized as new by Ulrich (in a letter to vom Rath). Named after Mr. J. C. Newbery, of Melbourne.

Niccochromite. *C. U. Shepard*, Min. Contr., 1877. A canary-yellow substance, occurring as a coating on zaratite, rarely on chromite, at Texas, Pa. On the ground of a partial blowpipe examination, it is concluded to be a "dichromate of nickel" (?).

NICCOLITE, Min., p. 60; App. II., p. 41.—**Anal.**, Colorado de Chañarcillo, Chili, *Domeyko*, 3d ed. Min. Chili, p. 185, 1879.

NIGRESCITE.—App. I., p. 12.

NIOBITE.—See *Columbite*, p. 29.

Nitrobarite. *Groth* (Z. Kryst., vi., 195, 1881) has described crystals of barium nitrate (barytsalpeter), from Chili. They are in apparent octahedrons, formed of the + and − tetrahedrons; also in spinel-like twins. According to Wulff (ib., iv., 122), the species is tetartohedral. The crystals are colorless, in part covered with a thin brownish-black coating resembling wad. Exact locality unknown. H. C. Lewis (Amer. Naturalist, xvi., 78, 1882) has proposed the name NITROBARITE for the species.

NITROGLAUBERITE.—App. II., p. 41.

Nocerina—NOCERITE. Announced by *Scacchi* in a preliminary note (Accad. Linc. Trans., III., v. 270, 1881), as occurring in volcanic bombs in the tufa of Nocera. In white acicular crystals, referred to the rhombohedral system. In composition regarded as a double fluoride of calcium and magnesium. Associated with fluorite, some brown crystals referred to amphibole, and minute crystals in hexagonal prisms, perhaps a variety of microsommite. The exterior of the bombs is covered with mica.

NOHLITE.—App. II., p. 41.

NOSITE.—Min., p. 333; App. II., p. 42.

NOUMEAITE, NOUMEITE, NUMEITE.—See *Garnierite*, p. 50.

OCTAHEDRITE, Min., p. 161; App. II., p. 41.—**Cryst.**, Memoir, Lercheltini Alp, Binnenthal (wiserine), *Klein*, J. Min., 1875, 337. Cavradi, Tavetsch, *vom Rath*, Ber. Ak. Berlin, 1875, 536 (Pogg. Ann., clviii., 402, 1876). Wettin, *Lüdecke*, Z. gesammt. Nat., III., iii., 394, 1878. Tavetsch, Brazil, etc., *Groth*, Min.-Samml. Strassburg, p. 108, 1878. Binnenthal, *v. Zepharovich*, Lotos, 1880. *Seligmann*, J. Min., 1881, ii., 269. Rauris, Salzburg, *Vrba*, Z. Kryst., v., 417, 1881.

Occurrence in nearly colorless transparent crystals, Brindletown, Burke Co., N. C., *Hidden*, Am. J. Sc., xxi., 160, 1881. In quartz at Nil-St.-Vincent, *de Koninck*, Bull. Ac. Roy. Belg., II., xlvi., 245, 1878.

Mallard (Ann. Min., VII., x., 137, 1876) describes the optical peculiarities of crystals from Brazil, and decides upon the monoclinic character of the fundamental individuals. See also *Brookite*, p. 18.

ŒLLACHERITE, Min., p. 489.—Habachthal, Salzburg. Occurrence in mica schist (anal. by F. Bergmann), *Sandberger*, J. Min., 1875, 624; ib., 1879, 867. See also *Mica Group*, p. 77.

OKENITE.—Min., p. 398; App. II., p. 41.

OLDHAMITE.—App. II., p. 41.

OLIGOCLASE, Min., p. 346; App. II., p. 41.—**Cryst.**, Antisana, Andes, *vom Rath*, ZS. G. Ges., xxvii., 301, 1875; Bodenmais, Z. Kryst., iv., 481. Mt. Gibele, Pantellaria, *Förstner*, Z. Kryst., i., 551, 1877. *Klein*, J. Min., 1879, 518. *Des Cloizeaux*, Bull. Soc. Min., iii., 157, 1880.

Anal., Dürrmorsbach, *Haushofer*, Z. Kryst., iii., 602.

See also *Feldspar Group*, p. 45.

OLIVINE.—See *Chrysolite*, p. 27.

OMPHACITE, Min., p. 223.—See *Pyroxene*, p. 100.

ONOFRITE, Min., p. 56.—From Marysvale, Southern Utah. Observed by *Newberry*, and described by *Brush* (Am. J. Sc., III., xxi., 312, 1881), as follows: Massive, without cleavage. H. = 2·5. G. = 7·62. Lustre metallic, brilliant on the fresh fracture. Color and streak blackish gray. Fracture conchoidal. Analysis by Comstock:

	Se	S	Hg	Zn	Mn		
(⅔)	4·58	11·68	81·93	0·54	0·69	=	99·42.

Formula essentially Hg (S,Se), with S : Se = 6 : 1, corresponding nearly with the onofrite of Haidinger, which has, according to H. Rose, S : Se = 4 : 1; with which it also agrees in physical characters.

Brush gives an historical statement as to the occurrence of American mercuric sulphoselenides. He also calls attention to the essential identity of *guadalcazarite* of Petersen (App. II., p. 25, also Rammelsberg, Min. Chem., 1875, p. 79) with the *metacinnabarite* or black mercuric sulphide of Moore (App. I., p. 10), and shows that *metacinnabarite*, HgS, G. = 7·72, *onofrite* (Utah), 6HgS + HgSe, G. = 7·62 (calculated 7·64), *onofrite* (San Onofre), 4HgS + HgSe, and *tiemannite*, HgSe, G. = 7·27, undoubtedly form an isomorphous series. The specific gravity given in Dana's Min., p. 56, for onofrite (5·56) is incorrect; that number belongs to a gray mineral of doubtful character also mentioned by Del Rio (see Brush, l. c.).

A mineral partially described by *D'Achiardi* as a ferriferous variety of guadalcazarite is provisionally called LEVIGLIANITE by him. A qualitative examination showed that it contained no selenium, and more zinc and iron than the original mineral. From the mercury mine of Levigliani, near Seravezza, in the Apuan Alps, Italy, Att. Soc. Tosc., ii., 112, 1876.

Ontariolite.—See *Scapolite*, p. 106.

OPACITE.—App. II., p. 41.

OPAL, Min., p. 198; App. II., p. 42.—Artificial opal, *Bertrand*, Bull. Soc. Min., iii., 57, 1880.

Formation of vein opal in the andesite of the Gleichenberg, Kispatic, Min. Petr. Mitth., iv., 122, 1881.

A variety of opal from Mt. Blackmore, Montana, has been called BLACKMORITE by Peale, Hayden's Report, 1872, p. 169.

ORILEYITE.—App. I., p. 12.

ORPIMENT, Min., p. 27.—Occurrence in the trachytic region of Tolfa, Rome, *Sella*, Trans. Accad. Linc., III., i., 66, 1877. In Iron Co., Utah, *W. P. Blake*, Am. J. Sc., III., xxi., 219, 1881.

ORTHITE, Min., p. 285; App. II., p. 42.—Cryst., Auerbach, in granular limestone, *vom Rath*, Ber. nied. Ges. Bonn, Jan. 8, 1881.

Microscopic examination of specimens from different localities, *A. Sjögren*, Geol. För. Förh., iii., 258, 1877.

Discussion of composition with many analyses, *Engström*, Inaug. Diss. Upsala, 1877 (Z. Kryst., iii., 191, 1878). A much altered orthite (12 to 14 p. c. H_2O), blackish brown to red, is called **VASITE** by Engström.

Slättåkra, analysis by Cedervall and Jönsson, *Blomstrand*, Minnesskrift Fys. Sällsk, Lund, 1878, p. 3.

ORTHOCLASE, Min., p. 352; App. II., p. 42.—Cryst., Bellingen, Westerwald (sanidine), *v. Rath*, Pogg. Ann., clviii., 400, 1876. Cornwall, penetration twins (tin oxide pseudomorph), *Laspeyres*, Z. Kryst., i., 204; i., 344, 1877. Albani Mts. (sanidine), *Sella*, Z. Kryst., i., 243, 1877. Fichtelgebirge, twins, *Haushofer*, Z. Kryst., iii., 601, 1879. Warmbrunn, Silesia, twins, *Klockmann*, ZS. See also *Feldspar Group*, p. 45, and *Microcline*, p. 80.

Oryzite (Orizite). *Grattarola*, Att. Soc. Tosc., iv., 226, Nov. 9, 1879.

In minute crystals, 1 to 3 mm. long, and 1 to 1·5 mm. thick. Prismatic with $I \wedge I = 134°$–138°: 1-ĭ ∧ 1-ĭ = 147°. Triclinic, according to Grattarola, but the measurements are stated to be approximate only, and those given are not sufficient to determine the form. H. = 6. G. = 2·245. Lustre vitreous to pearly. Color and streak white. Analyses:

	SiO_2	Al_2O_3	CaO	H_2O	
1.	59·54	16·79*	8·67	14·84,	MgO, alkalies tr. = 99·84.
2.	59·20	15·71	10·31	14·38,	" " " = 99·60.

* With some CaO.

Soluble in warm HCl, with the separation of gelatinous silica. B. B. swells up "and fuses easily." Named from *ορυζα*, *rice*, in allusion to the similarity of the crystals to rice grains. [Groth (Z. Kryst., iv., 641) calls attention to the similarity to heulandite in form and composition (with which the author regards it as being dimorphous), and justly remarks that the description is not sufficiently complete to establish its independence.] From the granite blocks in the Foresi collection, which have popularly gone by the name of the "Four Evangelists," and which formed part of the granitic vein of the "Masso Foresi," or Fonte del Prete, Elba. The same source has yielded tourmaline, beryl, castorite, pollucite, apatite, etc.

OSBORNITE.—App. I., p. 12.

OTTRELITE, Min., p. 506; App. II., p. 43.—A variety of ottrelite is called **VENASQUITE** by Damour (see *Bourbée*, Bains et courses de Luchon, 1857, and *Damour*, Bull. Soc. Min., ii., 167, 1879). Occurs in masses having a lamellar and radiated crystalline structure. Cleavage in one direction. H. = 5·5. G. = 3·26. Color grayish black. Streak gray. Opaque. Analysis, Damour, l. c.:

SiO_2	Al_2O_3	FeO	MgO	H_2O	
44·79	29·71	20·75	0·62	4·93	= 100·80.

This corresponds closely with the formula (Fe,Mg) $[Al_2]Si_3O_{10}$ + aq. B. B. fusible with difficulty on thin edges; yields a magnetic slag on charcoal. Not attacked by acids. From Vénasque, in the Pyrenees.

Oxammite. A name given by Shepard (App. I., p. 6) for crystals supposed to be ammonium oxalate, from the guano of the Guanape Islands. *Raimondi*, under the name of **guanapite**, has described (Min. Pérou, pp. 30, 38, 1878) what is apparently the same substance examined by Shepard. Occurs in small flattened (4 to 5 mm. long) grains, with lamellar structure. Sometimes in elongated prismatic (orthorhombic) crystals; also pulverulent. Color yellowish white. Lustre silky. Transparent. Inodorous. Volatilizes completely with heat. An oxalate of ammonia. Found with mascagnite, which it much resembles, in the guano of the Guanape Isles.

J. A. Tanner, Jr. (Chem. News, xxxii., 162, 1875), has analyzed the Guanape mineral, and obtained (after deducting 5·54 p. c. organic matter): NH_4 21·95, C_2O_4 53·30, H_2O 24·75, corresponding to $C_2(NH_4)_2O_4 + 2aq$, which requires: NH_4 22·50, C_2O_4 55·00, H_2O 22·50. [Raimondi's name is based on a partial description, Shepard's name on a mere statement in a single sentence; as, however, the name guanapite has been previously used (App. I., p. 6), the other, though not free from objection, may be accepted.]

Ozocerite, Min., p. 732; App. II., p. 43.—Description of a related mineral wax from Utah, *Newberry*, Am. J. Sc., III., xvii., 340, 1879.

From Kinghorn-ness, Scotland, anal., *Macadam*, Rep. Brit. Assoc., 1879, 309, or Ch. News, xl., 48, 1879. Galicia, *Paul*, Verh. G. Reichs., 1881, 131.

Pachnolite, Min., p. 129.—According to *Groth* (Tab. Uebers. Min., 41, 1882), the true relation of the species pachnolite and thomsenolite has been recently established by Brandl. **Pachnolite** is monoclinic, with $\beta = 89° 40'$, and c (vert.) : $b : \dot{a} = 1·5320 : 1 : 1·1626$, and has the composition $[Na,Ca]F_3 + Al_2F_6$. It is consequently a cryolite, with two sodium atoms replaced by one calcium atom.

Thomsenolite, on the same authority, is monoclinic, with $\beta = 89° 37\frac{1}{2}'$, and c (vert.): $b : \dot{a} = 1·0877 : 1 : 0·9959$; and has the composition $[Na,Ca]F_3 + Al_2F_6 + H_2O$.

On earlier discussions of the relations of these species, see: *Knop*, Ann. Ch. Pharm., cxxvii., 61, 1866; *Wöhler*, J. Min., 1876, 58; *König*, Proc. Ac. Nat. Sc. Philad., 1876, 42; *Krenner*, J. Min., 1877, 504; *Klein*, J. Min., 1877, 808. **Pyroconite** of *Wöhler* is the same as var. A pachnolite of Knop.

Palagonite, Min., p. 483; App. II., p. 43.—*Penck*, after an exhaustive study of many so-called palagonite rocks, concludes that no such mineral exists; that most of the material, which has received that name and been examined, is a mixture of different substances, consisting largely of the glassy ejected bombs from a basaltic magma, ZS. G. Ges., xxxi., 504, 1879.

Pandermite.—See *Priceite*, p. 97.

Paragonite.—Min., p. 487; App. II., pp. 43, 63.—See also *Cossaite*, App. II., p. 63.

Parailmenite. Same as the doubtful paracolumbite (Min., p. 148), from Taunton, Mass., *C. U. Shepard*, Am. J. Sc., III., xx., 56, 1880.

Parankerite.—See *Ankerite*, p. 6.

Parastilbite.—See *Epistilbite*, p. 42.

Parisite, Min., p. 702.—Absorption bands in spectrum (Ce,La,Di), *Cossa*, Accad. Linc. Mem., III., iii., 29, 1878. See also *Bastnäsite*, under Tysonite, p. 126.

Paroligocalse. **Paroligoklas.** *E. E. Schmid*, Jenaer. Denksch., 1880 (J. Min., 1881, i., 78 ref.).

A problematical substance occurring in indistinct prisms, with calcite grains, imbedded in th[illegible] mass of a rock found between Ilmsenberg, Quäriberg, and Silberberg, in the [illegible] The rock has a specific gravity of 2·666–2·677, and in thin sections shows an opaque ground-mass of ferrite, with the macroscopic prisms of a pale yellow color. Extinction parallel and perpendicular to the axis of prism.

Analyses : (1) of rock entire; (2) portion soluble in dilute HCl; (3) soluble in concentrated HCl; (4) insoluble remainder.

	SiO_2	Al_2O_3*	Fe_2O_3†	CaO	MgO	Na_2O	K_2O	CO_2	ign.	
1.	45·74	16·07	14·74	6·31	2·78	2·97	4·71	4·32	2·22	= 99·01.
2.	....	0·66	2·37	6·31	0·22	0·28		4·32	0·28	= 14·44.
3.	4·59	2·08	11·10	....	1·24	0·19	0·09	....	....	= 19·29.
4.	41·15	13·33	1·27	....	1·27	2·66	4·46	....	4·60	= 64·60.

* With P_2O_5. † With TiO_2 and Mn_2O_3.

The author gives for the ratio in the insoluble part of $RO : Al_2O_3 : SiO_2 = 0·94 : 3 : 8·90 = 1 : 3 : 9$, and calls the mineral *paroligoclase*, in allusion to the fact that this is the ratio of oligoclase. [Rosenbusch (J. Min., l. c.) suggests that the substance may belong to the scapolite group; in any case, on the basis of so imperfect an examination, it has no claim to a place as a mineral species, and should never have received a name.]

Partzite, Min., p. 188.—**Anal.**, Mine of San Lorenzo, province of Huaylas, and mine des Italiens, province of Cajatambo, Peru, *Raimondi*, Min. Pérou, pp. 83, 86, 87, 1878.

Passyite.—See *Quartz*, p. 101.

Pattersonite.—Min., p. 801; App. I., p. 18; II., p. 43.

Pealite.—App. II., p. 43 (24).

Peckhamite. *J. L. Smith*, Am. J. Sc., III., xix., 462; xx., 136, 1880.

Occurs in rounded nodules in the meteorite of Emmet Co., Iowa. Shows a more or less distinct cleavage. G. = 3·23. Lustre greasy, opalescent. Color light greenish yellow. Two analyses (1) on 0·1 gr., (2) on 0·35 gr., gave :

	SiO_2	FeO	MgO	
1.	49·50	15·88	33·01	= 98·39.
2.	49·59	17·01	32·51	= 99·11.

These correspond to $R_4Si_3O_{10}$, which Smith resolves into $2(RSiO_3) + R_2SiO_4$, that is, 2 molecules of enstatite and 1 of chrysolite. Named after Prof. S. F. Peckham.

Pectolite, Min., p. 396; App. II., p. 43.—A mineral, very near pectolite, is called **walkerite** by *Heddle* (Min. Mag., iv., 121, 1880). In radiating and interlacing fibres, resembling ordinary pectolite. H. = 4·5. G. = 2·712. Cream-colored, slightly pinkish. Lustre brilliant, pearly. Phosphoresces on being broken, or on application of heat. Analyses : 1, Walker (anal. 10, Dana, Min., p. 397); 2, 3, Heddle :

	SiO_2	Al_2O_3	FeO	CaO	MgO	K_2O	Na_2O	H_2O	
1.	54·00	....	....	30·79	2·59	....	5·55	5·43	= 98·36.
2.	53·22	0·9	0·21	26·18	6·81	undet.		5·23.	
3.	52·20	....	1·33	28·64	5·12	0·85	6·50	5·28	= 99·92.

Calculated formula: $Na_2MgCa_4Si_7O_{20}, 2H_2O$ or $H_2Na_2MgCa_4Si_7O_{21} + aq$, requiring: SiO_2 53·71, CaO 28·65, MgO 5·12, Na_2O 7·92, H_2O 4·60 = 100. Found in the diabase of Corstorphine Hill, near Edinburgh, Scotland. Described by the early English mineralogist, Dr. Walker, as pectolite, after whom it is named. [The difference from pectolite is so small as not to seem to require its separation.]

Peganite.—See *Variscite*, p. 128.

Pelagite. *A. H. Church*, Min. Mag., i., 50, 1876; *Gümbel*, Ber. Ak. München, 1878, p. 189.

A name given by Church (l. c.) to the manganese nodules obtained by the "Challenger" from the bottom of the Pacific, between Japan and the Sandwich Is., at a depth of 2740 fathoms. Characters, as follows: H. = 3·5. G. = 1·89. Color brownish black. Streak somewhat shining. Powder between blackish brown and clove brown. Fracture conchoidal; fragile. In the closed tube gives off water having a slight alkaline reaction. B. B. contracts, becomes black, and fuses on the edges. With HCl dissolves with the liberation of chlorine and separation of silica. The nodules have a concretionary structure, consisting of concentric layers, and having a core of indurated red clay, and, in one case, of pumice; the material was regarded as homogeneous. Gümbel (l. c.) describes nodules from the same source. Analyses: (1) Church; (2) Schwager (quoted by Gümbel).

SiO_2 MnO_2 Al_2O_3 Fe_2O_3 H_2O
1. 10·37 30·22 3·30 20·02 34·55*, Cl 0·71, MgO, CaO, CuO, Na_2O, Cl, P_2O_5, etc., 0·83 [= 100.
2. 16·03 23·60 10·21 27·46 17·82, MgO 0·18, CaO 0·92, CuO 0·02, CoO, NiO 0·01. [BaO 0·01, Na_2O 2·36, K_2O 0·40, TiO_2 0·66, Cl 0·94, P_2O_5 0·02, SO_3 0·48, CO_2 0·05 = 101·17.

* At a red heat 10·0 p. c.

Other analyses by J. Y. Buchanan (Proc. Roy. Soc. Ed., ix., 287, 1877; Ch. News, xliv., 253, 1881) of specimens from different localities, show a wide variation in composition (24·4–35·3 MnO_2 and 18–24·8 Fe_2O_3). [Although great interest attaches to these nodules they cannot in any sense claim to be a distinct mineral species, but are doubtless composite.]

Pelagosite. *K. Moser*, Tschermak, Min. Petr. Mitth., i., 174, 1878.

A substance occurring as a thin, dark-colored incrustation on limestone and dolomite, on the shores of the Mediterranean, as at the Island of Pelagosa (Moser). In some cases looking like varnish, and again resembling lichens. It consists of thin translucent layers exerting on polarized light the effect of aggregate polarization. An analysis by J. Cloëz on similar material from Cape Ferrat, afforded: $CaCO_3$ 91·80, $MgCO_3$ 0·90, Fe_2O_3 0·25, SiO_2 1·22, NaCl 0·49, H_2O 4·56, organic matter 0·71 = 99·93. It is regarded as produced by the action of sea-water on the dolomite.

Des Cloizeaux and Vélain have observed similar coatings on the feldspathic rocks of Corsica, on the coast of Oran, and on basaltic lava on the coast of Réunion Island, Bull. Soc. Geol., vi., 86, 1878. [Not a mineral species.]

Pelhamine. *C. U. Shepard*, Contr. Min., 1876.—A serpentinous substance (altered asbestos), forming irregular seams and masses at the asbestos mine, at Pelham, Mass., resembling a black serpentine. Color dark greenish gray. H. = 5. G. = 2·9–3·2. B. B. infusible. Analysis: SiO_2 38·40, Al_2O_3 2·80, FeO 15·52, MgO [39·88], H_2O 3·40 = 100.

PENCATITE.—Min., p. 708; App. II., p. 43 (45).

PENNINITE, Min., p. 495; App. II., p. 43.—*Mallard* (Ann. Min., VII., x., 151, 1876) regards penninite (uniaxial) and clinochlore, or ripidolite (biaxial), as identical, both having a fundamental monoclinic form, but differing only in the method of grouping of the individuals. He calls attention to cases where a biaxial chlorite encloses a nucleus of a uniaxial chlorite, and explains the latter by the aggregation analogous to corundum.

Analyses of penninite, ripidolite, and related species from Scottish localities, *Heddle*, Trans. Soc. Edinb., xxix., 55 et seq., 1879. Anal. (by van Wervecke), pseudophite, Markirch, Vosges, *Groth*, Z. Kryst., i., 509, 1877.

Penwithite. *J. H. Collins*, Min. Mag., ii., 91, 1878; iii., 89, 1879.

Massive. H. = 3·5. G. = 2·49. Lustre vitreous Color dark amber to reddish brown. Transparent. Fracture conchoidal. Brittle. Analysis: $(\frac{3}{3})$ SiO_2 36·40, MnO 37·62, FeO 2·52, H_2O 21·80, MnO_2 tr., U_2O_3 0·30, Cu tr. = 98·64. Formula calculated by author: $MnSiO_3 + 2aq$, requiring: SiO_2 35·9, MnO 42·5, H_2O 21·5 = 100. B. B. fuses with difficulty. Occurs with quartz and rhodochrosite, in the district of Penwith (whence name), West Cornwall. [The author mentions, that if the coarse powder is digested in HCl, the manganese is dissolved out and the silica left colorless; he also mentions related substances with SiO_2, varying from 22 to 57 p. c., and G. as high as 3·4. It would seem, consequently, very doubtful whether this is to be regarded as a true mineral species.]

Percylite, Min., p. 122; App. II., p. 48.—Believed to occur at Mina San Rafael, Galeria al Norte, Bolivia, *Gregory*, Min. Mag., ii., 251, 1879. Mt. de Challacollo, Tarapaca, Peru, *Raimondi*, Min. Pérou, p. 174, 1878.

Perofskite, Min., p. 146; App. II., p. 48.—Occurrence as a microscopic constituent of nephelite-pikrite, in Bohemia, *Boricky*, Ber. Böhm. Ges., Oct. 13, 1876, p. 227. From the Val Malenco (anal. by Mauro), *Strüver*, Trans. Accad. Linc., III., iv., 210, 1880.

The question of the crystalline system of perofskite has been discussed by *von Kokscharof*, Min. Russl., vi., 388, 1874; vii., 875, 1878; viii., 89, 1881 (J. Min., 1878, 38); *Des Cloizeaux*, ZS. G. Ges., xxvi., 932, 1874 ; J. Min., 1877, 160; ib., 1878, 43, 872; *Baumhauer*, Z. Kryst., iv., 187, 1879. The etching experiments of Baumhauer, supported by optical examinations, seem to prove that, as urged by von Kokscharof and accepted by Des Cloizeaux, the mineral is orthorhombic, and owes its form and optical properties to a complicated system of twinning.

An altered perofskite from Magnet Cove, Arkansas, is called HYDROTITANITE by *König* (Acad. Nat. Sci. Philad., 82, 1876). Color yellowish gray. G. = 3·681. Soft. An analysis afforded: TiO_2 82·82, Fe_2O_3 7·76, MgO 2·72, CaO 0·80, H_2O 5·50, V tr. = 99·60. [Indeterminate decomposition products are not mineral species.]

Petalite, Min., p. 229; App. II., p. 48.—**Anal.**, Elba, *Rammelsberg*, Ber. Ak. Berlin, 1878, 9. Discussion of chemical composition and relation to spodumene, *Dölter*, Min. Petr. Mitth., i., 529, 1878.

An alteration product of castorite, from Elba, has been called HYDROCASTORITE by G. Grattarola (Boll. Com. Geol., 1876, 323). Occurs as a mealy aggregate of fine crystalline needles, surrounding a nucleus of the original mineral. The microscopic prismatic crystals sometimes obliquely cut off (70°); extinction parallel the prism. H. = 2. G. = 2·16. Color white. Analyses: 1, Grattarola, on material not entirely pure; 2, Sansoni (Att. Soc. Tosc., iv., 320, 1879).

	SiO_2	Al_2O_3	CaO	MgO	H_2O		
1.	59·59	21·35	4·38	....	14·66	=	99·98.
2.	58·18	19·70	4·17	0·50	15·96	=	98·46.

For the latter the not very simple formula : $Ca_2[Al_2]_5Si_{26}O_{69}$ + 24aq, is calculated. [Needs further examination.]

Petzite.—Min. p. 146; App. II., p. 43; see also *Hessite*, App. III., p. 58.

Phäactinite.—See *Amphibole*, p. 5.

Pharmacolite, Min., p. 554 ; App. II., p. 48.—**Cryst.**, *Schrauf*, Z. Kryst., iv., 284, 1879.

Pharmacosiderite, Min., p. 578.—From Schemnitz, Hungary, Min. Mitth., 1875, 109. From Garonne, Dept. du Var, *Pisani*, C. R., lxxxiv., 1512, 1877.

Pseudo-isometric, according to *Bertrand*, Bull. Soc. Min., iv., 256, 1881.

Phenacite, Min., p. 263 ; App. II., p. 48.—**Cryst.**, with catalogue of observed planes, *Seligmann*, J. Min., 1880, i., 129. From Switzerland, perhaps Val Giuf, *Websky*, Ber. Ak. Berlin, 1880, 1007.

Anal., Cerro del Mercado, Durango, Mexico, *Chrustschoff*, Z. Kryst., iii., 634, 1879.

Phengite.—See *Mica Group*, p. 77.

Philadelphite.—See *Vermiculite*, p. 129.

Phillipite. *I. Domeyko,* 5th Appendix Min. Chili, 1876; 3d ed. Min. Chili, p. 248, 1879.

Compact, granular, or with fibrous structure, transverse to veins in the chalcopyrite. Lustre vitreous. Color azure blue. Translucent, astringent. Composition approximately given by the formula, $CuSO_4 + [Fe_2]S_3O_{12} + n aq$. Analysis gave: SO_3 28·96, Fe_2O_3 9·80 (iron subsulphate 2·28), CuO 14·39, MgO 0·85, H_2O 43·72, Al_2O_3 tr. = 100. Soluble in water, but unaffected by exposure to the air. Found at the copper mines in the Cordilleras of Condes, province of Santiago, Chili. Produced from the decomposition of chalcopyrite, and found in small irregular masses and bands with it in an argillaceous ochre.

PHILLIPSITE, Min., p. 438; App. II., p. 43.—Crystalline system monoclinic, with a higher degree of pseudo-symmetry, due to repeated twinning, analogous to harmotome, *Streng,* J. Min., 1875, 585; *Trippke,* ZS. G. Ges., xxx., 178, 1878 (or J. Min., 1878, 681, 880); *Fresenius,* Z. Kryst., iii., 42, 1879; *v. Zepharovich,* Z. Kryst., v., 96, 1880. The monoclinic character of phillipsite was first assumed by *Groth,* Tabell. Uebers. Min., pp. 62, 104, 1874.

Recent formation at Bourbonne-les-Bains, *Daubrée,* C. R., lxxx., 463, 1875; do. in Algiers, ib., lxxxiv., 157, 1877.

PHŒNICOCHROITE, Min., p. 630.—Made artificially, *Meunier,* C. R., lxxxvii., 656, 1878.

PHLOGOPITE, Min., p. 302.—See *Mica Group,* p. 77.

PHOLERITE, Min., p. 472; App. II., p. 44.—Anal., Distr. San Pablo, Peru, *Raimondi,* Min. Pérou, 302, 1878.

PHOSGENITE, Min., p. 703.—Cryst., Monte Poni, Sardinia, showing a close agreement with the results of *v. Kokscharof,* from Gibbas, *Hansel,* Z. Kryst., ii., 291, 1878. See also Min. Russl., viii., 118, 143, 1881.

Recent formation at Bourbonne-les-Bains, *Daubrée,* C. R., lxxxi., 182, 1875. Made artificially, *Friedel* and *Sarasin,* Bull. Soc. Min., iv., 175, 1881.

PHOSPHOCHROMITE, App. I., p. 12.—Pisani (Bull. Soc. Min., iii., 196, 1880) has analyzed a phospho-chromate from Beresofsk, which is near the *phosphochromite* of Hermann (App. I., see laxmannite). It occurs in mammillary forms, having a crystalline surface. Color reddish orange; powder yellow. The analysis gave:

P_2O_5	CrO_3	PbO	CuO		
9·78	15·80	70·60	4·57	=	100·75.

The formula is $Pb_3P_2O_8 + (Pb,Cu)CrO_4$.

Shepard has used the same name for a supposed substance, the existence of which even is not proved; see *Elroquite,* p. 41.

Phosphuranylite. *F. A. Genth,* Amer. Chem. J., i., 92, 1879.

Occurs as a pulverulent incrustation; shows with the microscope rectangular scales, with pearly lustre. Color deep lemon yellow. Analysis:

P_2O_5	UO_3	PbO	H_2O		
11·30	71·73	4·40	10·48	=	97·91.

The lead is regarded as being present as cerussite, which was visible under the microscope; deducting this the result becomes: P_2O_5 12·08, UO_3 76·71, H_2O 11·21 = 100. For this the formula is deduced: $(UO_2)_3P_2O_8 + 6aq = P_2O_5$ 12·75, UO_3 77·56, H_2O 9·69. B.B. in the closed tube yields water, and becomes brownish yellow on cooling. Easily soluble in ric acid. Occurs with other uranium minerals at the Flat Rock mine, Mitchell Co., ncrusts the quartz, feldspar, and mica.

ollite.—See *Dopplerite,* p. 38.

Picite. *A. Nies*, Ber. Oberhess. Ges. Nat. Heilk., xix., p. 112, 1880. *A. Streng*, J. Min., 1881, i., 116.

Amorphous; in thin coatings, or in small stalactitic and spherical forms. H. = 3–4. G. = 2·83. Color dark brown. Streak yellow. Lustre vitreous to greasy. Translucent. Fracture subconchoidal. Anistropic. Analysis: Nies, after deducting 2·10 p. c. insoluble:

P_2O_5	Fe_2O_3	Al_2O_3	H_2O		
24·47	46·50	1·00	28·03	=	100.

Formula: $4[Fe_2]P_2O_8 + 3[Fe_2]H_6O_6 + 27aq$ [but, as Nies remarks, it is by no means sure that the mineral is homogeneous]. From the Eleonore mine, near Bieben, and the Rothläufchen mine, near Waldgirmes, in the neighborhood of Giessen. Closely related, as shown by Nies, to the Picites resinaceus of Breithaupt (Handb. Min., i., 897), and to a phosphate mentioned by Boricky (Ber. Ak. Wien, lvi., 16, 1867) as occurring at the Hrbek mine, St. Benigna, Bohemia.

PICKERINGITE, Min., p. 653.—**Anal.**, Colorado City, Col., *Goldsmith*, Proc. Acad. Nat. Sc. Phil., 1876, 333. Argentine Republic (Schickendantz), *Brackebusch*, Min. Argentin., 74, 1875.

A related mineral is called SONOMAITE by *E. Goldsmith* (Proc. Ac. Nat. Sc. Philad., 1876, 263). Crystalline. G. = 1·604. Silky lustre. Colorless. Analysis:

	SO_3	Al_2O_3	FeO	MgO	H_2O		
(?)	38·54	8·01	1·78	7·33	[44·34]	=	100.

Formula: $3MgSO_4 + [Al_2]S_3O_{12} + 33aq$. From the neighborhood of the Geysers, Sonoma Co., California.

Picroallumogene of *G. Roster* (Boll. Com. Geol., 1876, 302) is another mineral very near pickeringite. Stalactitic; in nodular and fibrous radiated masses. Monoclinic or triclinic. Color white, with a rose-red tinge. Streak nearly white. Semi-translucent. Taste acid, bitter. Composition: $2MgSO_4 + [Al_2]S_3O_{12} + 28aq$ = SO_3 36·80, Al_2O_3 9·48, MgO 7·36, H_2O 46·36 = 100. Analysis:

SO_3	Al_2O_3	MgO	H_2O
36·38	9·16	8·19	45·69, K_2O 0·37, CoO tr. = 99·79.

Fuses easily in its own water of crystallization, and swells out, becoming opaque and porous. Dissolves in slightly warmed water, forming an acid solution, from which oblique prisms resembling gypsum separate on slow evaporation. Occurs with sulphur and melanterite, in the iron mine of Vigneria, Island of Elba.

PICROMERITE.—Min., p. 642; App. II., p. 44.

PICROPHARMACOLITE.—Min., p. 555; App. II., p. 41.

PICROSMINE, Min., p. 405.—**Anal.** of a related mineral, Haslau, Plötzbachthal, *Frenzel*, Min. Petr. Mitth., iii., 512, 1881.

PICROTEPHROITE.—See *Tephroite*, p. 120.

PIEDMONTITE, Min., p. 285.—Crystallographic, optical, and chemical examination, *Laspeyres*, Z. Kryst., iv., 435, 1880.

Pilarite.—See *Chrysocolla*, p. 26.

Pilinite. *A. von Lasaulx*, J. Min., 1876, 358.

Orthorhombic (on optical grounds). In minute (·005 mm. to ·01 mm.) prismatic crystals, having a rhombic section of about 120° and 60°; forming a fine felt-like mass, the needles often bent; resembles asbestos. Cleavage basal perfect, prismatic distinct. G. = 2·263. Lustre of needles silky. Color white to colorless. Needles pliable. Analysis. Bettendorff (l. c.):

SiO_2	$\underbrace{Al_2O_3, Fe_2O_3}$	CaO	Li_2O	$\underbrace{MgO, Na_2O, K_2O}$	H_2O		
55·70	18·64	19·51	[1·18]	tr.	4·97	=	100.

The formula proposed is $(Ca,Li_2)\,[Al_2]\,Si_8O_{18} + aq$. Fuses easily with strong intumescence to a sponge-like bead. Insoluble in acids, even on boiling. Occurs with quartz, epidote, and stilbite in cavities in the granite of Striegau, Silesia. Named from πίλινος, *made of felt.*

Pilolite. *Heddle*, Min. Mag., ii., 206, 1879.

Heddle has analyzed specimens of "mountain cork" (1, 2, 3, 4), and "mountain leather" (5, 6, 7), from several localities in Scotland, with the following results:

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	CaO	MgO	H_2O* (total)		
1. Portsoy	51·43	7·52	2·06	2·49	1·30	0·58	9·35	25·04	=	99·76.
2. Cabrach	51·00	12·88	0·09	2·68	0·08	....	7·54	24·74	=	99·73.
3. Tod Head	51·61	6·63	....	2·70	2·77	1·11	10·21	25·00	=	100·63.
4. Tay Port	54·37	11·27	0·21	1·09	0·33	0·98	9·49	22·41	=	100·16.
5. Tod Head	52·48	6·33	0·60	2·11	2·88	1·34	11·95	21·70	=	99·39.
6. Lead Hills	51·45	7·98	0·97	3·29	1·49	1·97	10·15	21·70	=	98·99.
7. Boyne Burn	51·10	6·81	2·27	2·82	1·01	0·86	10·16	23·90	=	98·93.

* H_2O at 100°: in (1) 10·88, in (2) 10·64, in (3) 9·27, in (4) 9·26, in (5) 5·99, in (6) 5·96, in (7) 9·2.

The quantivalent ratio for the above is approximately, $R : [R_2] : Si : H = 4 : 3 : 20 : 15$, and the calculated formula $Mg_4\,[Al_2]\,Si_{10}O_{27}, 15H_2O$.

The minerals have the characters ordinarily given under the names "mountain leather," and "mountain cork." Structure fibrous, more or less flexible and tough. Color white to pale buff, gray, etc. They occur in granular limestone, in granite veins, and in veins in sandstones and slates. Heddle states that the above mineral is not an alteration product of a variety of hornblende, but a distinct species. Named from πῖλος, *felt.* [Compare *xylotile*, p. 406.]

PINITE, Min., p. 479; App. II., p. 44.—**Anal.**; formed from andalusite, San Piero, Elba, *Grattarola*, Boll. Com. Geol., 1876, 333. Södertörn, Sweden (rosite and polyargite), *Palmgren*, Geol. För. Förh., i., 188, 1873.

From Eastern Massachusetts, analyses, occurrence, etc., *Crosby*, Am. J. Sc., III., xix., 116, 1880.

See also *Iolite*, p. 63, *Killinite* (under Spodumene), p. 112.

PISANITE, Min., p. 646.—Massa Marittima, Tuscany, optical exam., etc., SO_3 28·48, CuO 10·07, *C. Hintze*, Z. Kryst., ii., 309, 1878.

PITTICITE.—Min., p. 589; App. II., p. 44.

Plagiocitrite. *Sandberger; Singer*, Inaug. Diss., p. 13, Würzburg.

Monoclinic or triclinic. In microscopic crystals. G. = 1·881. Color lemon yellow. Translucent. Taste astringent. Analysis (after deducing 9·85 p. c. hygroscopic water):

SO_3	Al_2O_3	Fe_2O_3	FeO	NiO	CoO	MgO	CaO	Na_2O	K_2O	H_2O		
35·44	14·37	7·95	1·64	0·97	0·58	1·19	0·43	4·04	4·23	29·42	=	100·26.

Formula $R_2SO_4 + [R_2]SO_6 + 9aq$. Easily soluble in water, the solution giving an acid reaction; by boiling, Fe_2O_3 separates out free from SO_3. Decomposes on exposure, becoming orange yellow. B. B. swells up, fuses in its own water of crystallization, and leaves a reddish brown spongy residue. Occurs with other related sulphates at the Bauersberg near Bischofsheim vor der Rhön; derived from the decomposition of pyrite.

PLAGIONITE.—Min., p. 89; App. II., p. 44.

PLATINUM, Min., p. 10; App. II., p. 44.—Russia, *v. Kokscharof*, Min. Russl., vii., 143, 1875. *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xiv., 155, 1879.

(Eisenplatin) from Nischne Tagilsk, *Terreil*, C. R., lxxxii., 1116, 1876; made artificially, *Daubrée*, C. R., lxxx., 526, 1875.

Ural, associated with chrysolite, serpentine, chromite, *Daubrée*, C. R., lxxx., 707, 1875.

Nugget found near Plattsburgh, N. Y., analysis by *Collier*, Am. J. Sc., III., xxi., 123, 1881. Weight 104·4 grams. G. = 17·35 of platinum; G. = 10·446 of mass consisting of 46 p. c. of platinum, and 54 p. c. of chromite.

PLUMBALLOPHANE.—App. I., p. 12.

PLUMBIODITE.—App. II., p. 44.

PLUMBOCUPRITE.—App. II., p. 44.

Plumbomanganite. *Hannay*, Min. Mag., i., 151, 1877.

Massive, crystalline. G. = 4·01. Color dark steel gray, with a bronze tinge when exposed to the air for some time. Analysis gave: Mn 49·00, Pb 30·68, S 20·73 = 100·41, for which the formula $3Mn_2S + PbS$ is suggested. [An imperfect description of a single specimen of doubtful homogeneity and uncertain source is not a satisfactory basis for a new name.]

Plumbostannite. *A. Raimondi*, Minéraux du Pérou, p. 187, 1878.

Amorphous; structure granular. H. = 2. G. = 4·5 (too low because of intermixed quartz). Lustre feebly metallic. Color gray. Feel greasy, like graphite. Slightly ductile. Intimately mixed with small crystals of quartz. Analysis (deducting 38·8 p. c. quartz):

S	Sb	Sn	Pb	Fe	Zn		
25·14	16·98	16·30	30·66	10·18	0·74	=	100.

B. B. gives on charcoal antimonial fumes and a lead coating; yields metallic tin. Dissolves completely in HCl to which a little HNO_3 has been added. With concentrated nitric acid leaves a white residue of the oxides of tin and antimony and lead sulphate. From the district of Moho, province of Huancané, Peru; occurs with cassiterite and sphalerite. [Probably not homogeneous.]

POLLUCITE, Min., p. 249.—**Cryst.**, Elba, *Corsi*, Z. Kryst., vi., 200, 1881.

Anal., Elba, *Rammelsberg* (Ber. Ak. Berlin, 1878, 9,: SiO_2 [48·15], Al_2O_3 16·31, Cs_2O 30·00, Na_2O 2·48, K_2O 0·47, H_2O 2·59, corresponding to $H_2\overset{\prime}{R}_2[Al_2]Si_5O_{15}$. G. = 2·868; another analysis is given in ib., 1880, 669.

POLYARGYRITE.—App. I., p. 12.

POLYCRASE, Min., p. 523; App. II., p. 44.—**Cryst.**, *Brögger*, Z. Kryst., iii., 484, 1879.

Anal., Småland, Sweden, *Blomstrand*, Minnesskrift Fys. Sällsk., Lund, 1878, p. 19 (Z. Kryst., iv., 524).

Polydymite. *H. Laspeyres*, J. pr. Chem., II., xiv., 397, 1876.

Isometric; in octahedrons, frequently in polysynthetic twins, often tabular. Cleavage basal imperfect. H = 4·5. G. = 4·808–4·816. Lustre brilliant metallic on fresh fracture. Color light gray, easily tarnished. Analyses, 1, 2, Laspeyres, on 0·28 and 0·2 gr.:

	S	Ni	Co	Fe	Sb	As		
1.	40·27	53·51	0·61	3·84	0·51	1·04	=	99·78.
2.	39·20	53·13		4·12	1·15	2·30	=	99·90.

After deducting impurities (gersdorffite, ullmannite 5 p. c.), anal. 1 becomes S 41·09, Ni 54·30, Co 0·63, Fe 3·98 = 100, and from this the ratio is obtained, R : S = 4 : 5·096, corresponding to Ni_4Si_5 = S 40·55, Ni 59·45 = 100.

Insoluble in HCl, soluble in HNO_3 with separation of sulphur. B. B. decrepitates, in the closed tube gives a sulphur sublimate and fuses to a dark green magnetic bead. Occurs intimately mixed with gersdorffite, ullmannite, millerite, siderite, quartz, sphalerite, galenite, bismuthinite, and other minerals, at Grünau, in Sayn-Altenkirchen, Westphalia. [Closely related to beyrichite (App. I., p. 8), if not identical with it.]

Laspeyres (ib., p. 406) expresses the opinion that the nickelwismuthglanz, or saynite of von Kobell (grünauite of Nicol, Min. p. 47), from the same locality, is a polydymite, impure through the admixture of bismuthinite, also chalcopyrite, and galenite. This, considering the distinct crystalline form of the mineral, seems, as urged by Kenngott (J. Min., 1878, 180), to be doubtful, although perhaps true of the massive mineral analyzed by von Kobell.

POLYHALITE, Min., p. 641; App. II., p. 44.—*Precht* (Ber. Chem. Ges., xiv., 2138, 1881) gives the following description of KRUGITE, a supposed new mineral near polyhalite, found at the salt works of New Stassfurt : Crystalline. H. = 3·5. G. = 2·801. According to a microscopic and optical examination, a homogeneous compound. Analyses:

	$CaSO_4$	$MgSO_4$	K_2SO_4	H_2O	NaCl		
1.	63·15	13·71	18·60	4·16	0·38	=	100.
2.	63·85	13·34	17·85	4·20	0·80	=	100·04.

Calculated formula : $K_2SO_4 + MgSO_4 + 4CaSO_4$ + 2aq, requiring : $CaSO_4$ 62·24, $MgSO_4$ 13·74, K_2SO_4 19·90, H_2O 4·12 = 100. In cold water the magnesium sulphate is dissolved and gypsum and the double salt $K_2SO_4 + CaSO_4$ + 2aq are left insoluble; in hot water the magnesium and potassium sulphates are dissolved out, and only the gypsum is left behind. Named for the Mining Director, D. Krug, v. Nidda.

Posepnyte. *J. von Schröckinger*, Verh. G. Reichs., 1877, 128.

In plates and nodules, sometimes brittle, sometimes hard. Color generally dirty light green. G. = 0·85–0·95. Separated by ether into two parts; analyses by Dietrich, (1), of the portion soluble in ether ; (2), the insoluble portion:

	C	H	O		
1.	71·84	9·95	18·21	=	100.
2.	84·27	11·74	3·99	=	100.

The insoluble portion is regarded as being ozocerite, and for the rest the formula $C_{22}H_{36}O_4$ is calculated, requiring, C 72·52, H 9·89, O 17·59 = 100. From the Great Western mercury mine, Lake Co., California.

PREDAZZITE.—Min., p. 708; App. II., p. 45.

PREHNITE, Min., p. 410; App. II., p. 45.—**Cryst.**, Zöptau, *v. Rath*, Z. Kryst., v., 254, 1880.

Pyro-electrical properties, *Hankel*, Wied. Ann., vi., 55, 1879.

Anal. (and cryst.), Tuscany, *Corsi*, Boll. Com. Geol., 1878, 54; 1879, 155. Monte Catini (prehnitoid), *Bechi*, Z. Kryst., iv., 399; Trans. Accad. Linc., III., iii., 114, 1879. Kuchelbad, near Prague, *Preis* and *Vrba*, Ber. Böhm. Ges., 1879, p. 468. Between Huancavelica and Ayacucho, Prov. d'Angaraes, Peru, anal. (by Saldan), *Raimondi*, Min. Pérou, 313, 1878. Templeton, Canada, *Harrington*, Geol. Canada, 1878.

Chlorastrolite (Min., p. 412) is shown by Hawes (Am. J. Sc., III., x., 25, 1875) to be essentially an impure prehnite. An analysis gave him: SiO_2 37·41, Al_2O_3 24·62, Fe_2O_3 2·21, FeO 1·18, MgO 3·46, CaO 22·20, Na_2O 0·32 (?), H_2O 7·72 = 99·75. A microscopic examination proved the want of homogeneity.

Zonochlorite (Appendix II., p. 63) is probably also an impure prehnite; *Hawes* (Am. J. Sc., III., x., 24, 1875) obtained from an analysis of a dark green specimen: SiO_2 35·94, Al_2O_3 19·41, Fe_2O_3 6·80, FeO 4·51, MgO 2·48, CaO 22·77, Na_2O tr., H_2O 8·40 = 100·34. Microscopic examination showed the presence of green earthy particles as impurities disseminated through a white mineral.

PRICEITE, App. II., p. 45.—A mineral, apparently identical with priceite, has been called **PANDERMITE** by *vom Rath*, Ber. nied. Ges. Bonn, July 2, 1877. Massive, finely crystalline, resembling marble. Color snow white. H. = 3. G. = 2·48. Calculated composition, $Ca_2B_6O_{11} + 3aq = B_2O_3$ 55·85, CaO 29·79, H_2O 14·36 = 100. Analyses, 1, vom Rath; 2, Pisani, Min., p. 215, Paris, 1875

	B_2O_3	CaO	FeO	MgO	K_2O	H_2O		
1.	[54·59]	29·33	0·30	0·15	0·18	15·45	=	100.
2.	[50·1]	32·0	....	....	....	17·9	=	100.

Occurs in more or less irregular lumps or nodules of varying size up to a ton, in gray gypsum, at Panderma, on the Black Sea.

Proidonina—**PROIDONITE**. *A. Scacchi*, Att. Accad. Napoli, vi., 1873 (Contrib. Min., ii., 65).

Silicon fluoride (SiF_4), observed in the exhalations at Vesuvius at the time of the eruption in 1872.

PROUSTITE, Min., p. 96; App. II., p. 45.—**Cryst.**, Chañarcillo, Chili, *Streng*, J. Min., 1878, 900.

PSEUDOAPATITE, Min., p. 531.—Pseudomorphous after pyromorphite, from the Churprinz mine, near Freiberg; analysis: P_2O_5 39·28, CaO 56·66, SO_3 1·42, CO_2 [2·64], Cl tr. = 100, *Frenzel*, Min. Petr. Mitth., iii., 364, 1880.

Pseudobrookite. *A. Koch*, Min. Petr. Mitth., i., 77, 344, 1878; *Gonnard*, Mem. Ac. Lyon, xxiv., 161, 1879–80; *Schmidt*, Z. Kryst., vi., 100, 1881.

Orthorhombic; in thin tabular (parallel $i\text{-}\bar{i}$) rectangular crystals, resembling some forms of brookite. Planes (Groth, Z. Kryst., iii., 306), $i\text{-}\bar{i}$, $i\text{-}\breve{i}$, I, $i\text{-}\bar{2}$, $1\text{-}\bar{i}$, $\frac{1}{2}\text{-}\bar{i}$, $1\text{-}\breve{i}$, $1\text{-}\breve{3}$; $i\text{-}\bar{i} \wedge I$ = 135° 54′, $i\text{-}\breve{i} \wedge 1\text{-}\bar{i}$ = 138° 41′. Cleavage brachydiagonal, distinct; $i\text{-}\bar{i}$ vertically striated. H = 6. G. = 4·98. Lustre adamantine on crystalline faces, on fracture surfaces greasy. Color dark brown to black; the thinnest crystals red and translucent. Streak ochre yellow. Fracture uneven to subconchoidal.

Analysis (on 0·1 gr.): TiO_2 52·74, Fe_2O_3 42·29, ign. 0·69, Al_2O_3, CaO, MgO, SiO_2 tr. = 95·72; the state of oxidation of the iron is in doubt. The author regards it as dimorphous with menaccanite. B. B. nearly infusible; reacts for iron and titanium with the fluxes. Decomposed in part by boiling HCl, wholly so by H_2SO_4. Found with szaboite, in cavities in the andesite of the Aranyer Berg, Transylvania; also with szaboite and tridymite in the trachyte of Riveau Grand, Monte Dore.

Groth (l. c.) shows that the crystallographic determinations of Koch are faulty, and that the crystals may be referred to the axes of brookite by making $i\text{-}\bar{i}$ the basal plane, with which it may be identical, only differing in the large amount of iron. Vom Rath, however (Ber. nied. Ges. Bonn, March 3, 1879), thinks this improbable, on the ground that, with this change of position, the analogy with brookite in the vertical striation would no longer exist; he also urges that, as yet, no one of the three forms of TiO_2 has been found in volcanic rocks.

Pseudocotunnite. *A. Scacchi*, Att. Accad. Napoli, vi., 1873 (Contrib. Min., ii., 38).

Observed in acicular yellow opaque crystals, destitute of lustre, accompanying cotunnite, at Vesuvius, as a result of the eruption of 1872. Composition probably $PbCl_2 + KCl$.

PSEUDOMALACHITE, Min., p. 568; App. II., p. 45.—*Schrauf* (Z. Kryst., iv., i., 1879) uses Bernhardi's name, **LUNNITE**, for the group of minerals which have been included (see Min.) under **PSEUDOMALACHITE**, on the hardly sufficient ground that the latter name suggests only the indistinctly crystalline or massive forms, which resemble malachite. For the crystalline varieties, which are pseudo-monoclinic (triclinic), have G. = 4·4, and correspond mostly to $Cu_5P_2H_4O_{12}$, he uses the name *dihydrite* (D); they show no loss at 200°. The names *ehlite* (E) and *phosphorocalcite* (P) he gives to the compounds $Cu_5P_2H_6O_{13}$ and $Cu_6P_2H_6O_{14}$, respectively, and regards the three as entering in varying proportions to form the different massive varieties; the latter have a lower specific gravity, and lose water on ignition at 200°. Analyses: 1, "dihydrite," crystalline variety from Rheinbreitbach; 2, "ehlite," in light grayish green hemispherical forms, from Ehl; 3, pseudomalachite, resembling malachite in structure, from Nischne-Tagilsk; 4, spherical form, with concentric structure, deep emerald green, from Libethen.

		P_2O_5	CuO	H_2O
1.	G. = 4·309	23·86	69·25	6·76, FeO 0·19 = 100·06.
2.	G. = 4·102	22·07	66·97	7·59, FeO 0·30, SiO_2 3·01 = 99·94.
3.	G. = 4·175	23·23	69·02	8·09 = 100·34.
4.	G. = 4·156	22·16	69·11	8·02, FeO 0·22, SiO_2 0·11 = 99·62.

According to Schrauf's view, anal. 1 corresponds to a molecular mixture of 3D + 1P: 2, after deducting 8·8 p. c. chrysocolla (CuH_2SiO_4 + aq), to simply "dihydrite;" 3, to D + E + P; 4, to 4P + 2E + D; where the letters D, E, P have the values explained above. [A more extended chemical study of these minerals, with regard to the possible mechanical mixtures in the massive varieties with concentric structure, is needed to establish the value of this very artificial hypothesis.]

Pseudonatrolite. *Grattarola*, Att. Soc. Tosc., iv., 229, 1879 (Boll. Com. Geol., 1872, 284).

Orthorhombic (?). In minute, needle-like crystals, 0·5 mm. thick; crystals not terminated, six planes in the prismatic zone. Extinction parallel to the axis. H. = 5–6. Lustre vitreous to pearly. Colorless, white in the mass. Analysis:

	SiO_2	Al_2O_3	CaO	MgO	Li_2O, Na_2O, K_2O	H_2O	
(⅓)	62·64	14·76	8·54	tr.	1·00	14·82	= 101·76

B. B. fuses less readily than natrolite. Partially soluble in HCl. From the granite of San Piero, Elba. [Needs further examination.]

PSEUDOPHITE.—See *Penninite*, p. 90.

PSILOMELANE, Min., p. 180.—Salm Chateau, Belgium, analyses, discussion of composition, *Laspeyres*, J. pr. Ch., II., xiii., 1, 176, 1876. Laspeyres mentions especially the "lithium-psilomelane," or LITHIOPHORITE, as described by Frenzel (App. I., p. 9).

According to *Weisbach*, the kakochlor, from Rengersdorf, near Görlitz, belongs with lithiophorite. An analysis by Iwaya is quoted by him (J. Min., 1878, 846), and a second is quoted by *Frenzel*, J. Min., 1880, ii., 113 (see also J. Min., 1879, 55).

A variety of psilomelane, from Kalteborn, is called CALVONIGRITE by *Laspeyres*, J. pr. Ch., II., xiii., 226, 1876.

Psittacinite. *F. A. Genth*, Am. J. Sc., III., xii., 35, 1876. New tellurate of lead and copper, id., Proc. Am. Phil. Soc., xiv., 229, 1874 (Appendix II., p. 55).

In thin crypto-crystalline coatings, sometimes small mammillary or botryoidal; also pulverulent. Color siskin-green to olive-green, sometimes with grayish tint. Analyses, Genth (l. c.), on material more or less impure through admixture of quartz and limonite:

	V_2O_5	PbO	CuO	H_2O	SiO_2	Al_2O_3	Fe_2O_3	MgO	CaO
1.	15·87	42·89	14·72	undet.	10·10	8·83	2·19	0·65	0·15.
2.	14·64	41·36	14·84	7·42	15·18	1·29	2·72	undet.	
3.	15·77	42·38	15·08	7·25	15·57	4·00.			
4.	9·96	27·12	9·75	undet.	48·84.				
5.	19·05	50·17	16·66	undet.	7·60.				

The mean quantivalent ratio deduced from the above for Pb : Cu : V : H = 1 : 0·98 : 2·25 : 2·15 = 9 : 9 : 20 : 18, corresponding to the formula $3Pb_3V_2O_8 + Cu_3V_2O_8 + 6CuH_2O_2 +$ 12aq, which requires: V_2O_5 19·32, PbO 53·15, CuO 18·95, H_2O 8·58 = 100. Related to chileite, Min., p. 612. B. B. fuses easily to a black, shining mass. Reacts for lead, copper, and vanadium with the fluxes. Soluble in dilute nitric acid.

Occurs associated with gold, cerussite, chalcopyrite, and limonite, on quartz, at the Iron Rod mine, and New Career mine, in the Silver Star District, Montana. Named from *psittacinus*, siskin or parrot green.

Pucherite, App. I., p. 12; II., p. 45.—Made artificially, *Frenzel*, J. Min., 1875, 680.

Occurrence at the "Arme Hilfe" mine, at Ullersreuth, near Hirschberg, Vogtland, and at the mine "Sosaer Glück," at Sosa, near Eibenstock, *Weisbach*, J. Min., 1880, ii., 113.

Pyrargyrite, Min., p. 94; App. II., p. 45.—Cryst., Andreasberg, *vom Rath*, Pogg. Ann., clviii., 422, 1876. Chañarcillo, Chili, *Streng*, J. Min., 1878, 913; also anal. (p. 916) showing 3·8 p. c. As. Andreasberg, Freiberg, etc., *Groth*, Min.-Samml. Strassburg, p. 62. 1878.

Pyrichrolite.—App. II., p. 45.

Pyrite, Min., p. 62; App. II., p. 45.—Cryst., Waldenstein, Carinthia, *Helmhacker*, Min. Mitth., 1876, 13. *V. Kokscharof*, Min. Russl., viii., 190, 1878. *Groth*, Min.-Samml. Strassburg, p. 31, 1878. Ordubad, Russian Armenia, *Websky*, ZS. G. Ges., xxxi., 222, 1879. Przibram, *Vrba*, Z. Kryst., iv., 357, 1880. Böckstein, Salzburg, *v. Zepharovich*, Lotos, 1875 (Z. Kryst., v., 270, 1880). Crystallo-genetic observations, *Scharff*, Abh. Senck. Ges., 1878.

Recent formation at Bourbonne-les-Bains, *Daubrée*, C. R., lxxx., 605, 1875.

Analyses, *Girard* and *Morin*, Ann. Ch. Phys., V., vii., 229, 1876.

Pyritolamprite.—App. II., p. 46.

Pyroaurite, Min., p. 179.—Described by *Heddle* (Min. Mag., ii., 107, 1878), from the island of Haaf-Grunay, Scotland. Occurs in thin seams in serpentine. Structure obscurely fibrous. Color silvery white. Lustre pearly. Analyses:

	Fe_2O_3	MgO	H_2O	CO_2		
1.	22·13	37·80	39·27	1·02	=	100·22.
2.	22·45	37·57	39·51	1·03	=	100·56.
3.	23·63	36·85	40·02	....	=	100·50.

B. B. infusible, becomes chocolate brown, and strongly magnetic. Soluble in acids. Heddle proposes to call this mineral IGELSTRÖMITE (after the discoverer), instead of pyroaurite, on the ground that the golden color is not essential.

Pyrochlore, Min., p. 512; App. II., p. 46.—See *Hatchettolite*, p. 56.

Pyrochroite, Min., p. 177.—Mossgrufva, Wermland, *Sjögren*, Geol. För. Förh., ii., 531, 1875; iii., 181, 1876; iv., 159, 1878. *Nordenskiöld* (anal. by Stahre), iv., 163, 1878. Occurs with manganosite (q. v.).

Pyroconite.—See *Pachnolite*, p. 88.

Pyroïdesine. *C. U. Shepard*, Cat. Meteorites, 1872.—A substance near serpentine. The mean of two analyses gave: SiO_2 42·45, MgO 33·07, FeO 6·35, H_2O 16·40. De Regla, Cuba.

Pyrolusite, Min., p. 165; App. II., p. 46.—Formed artificially, *Hannay*, Min. Mag., ii., 90, 1878.

Groth shows (Min.-Samml. Strassburg, p. 112, 1878), on the basis of measurements by Hirsch, that $I \wedge I = 99° 30'$.

Composition of the "Braunstein" group discussed, *Laspeyres*, J. pr. Ch., II., xiii., 176, 215, 1876.

From Gosalpur, Jabalpur distr., India, anal. *F. R. Mallet*, Rec. Geol. Surv. India, xii., 99, 1879.

Pyromorphite, Min., p. 535; App. II., p. 45.—**Cryst.**, Mine Friedrichssegen, in Nassau, *Seligmann*, Verh. Nat. Ver. Bonn, xxxiii., 257, 1876.

Baumhauer shows by the results of etching with solvents, that the crystals are pyramidally hemihedral, J. Min., 1876, 411.

On the relation of uniaxial pyromorphite to biaxial mimetite, *Bertrand*, Bull. Soc. Min., iv., 36; *Jannettaz*, ib., p. 39, 1881; *Jannettaz* and *Michel*, ib., p. 196 (see *Mimetite*, p. 81).

Anal., Dernbach, Nassau, *Hilger*, J. Min., 1879, 183.

Pyrophosphorite. *C. U. Shepard, Jr.*, Am. J. Sc., III., xv., 49, 1878.

Massive, earthy. H. = 3–3·5. G. = 2·50–2·58. Color snow-white, dull; also in part bluish gray, with small botryoidal structure. **Analyses**: Shepard (l. c.), 1, mean of two analyses; 2, same, after deducting impurities.

		P_2O_5	MgO	CaO	Fe_2O_3, Al_2O_3	SO_3	SiO_2	ign.		
1.	(½)	50·80	3·09	44·46	0·44	0·63	0·36	0·39	=	100·17.
2.		51·67	3·17	45·16 = 100.						

From 2, above, the following formula is calculated: $Mg_2P_2O_7 + 4(Ca_3P_2O_8 + Ca_2P_2O_7)$, which requires: P_2O_5 51·57, CaO 45·20, MgO 3·23 = 100. Named in allusion to its apparent composition as a pyrophosphate. From the West Indies; exact locality unknown. [Was the material analyzed homogeneous? Needs further examination.]

Pyrophyllite, Min., p. 454; App. II., p. 46.—**Analyses**, *Helmhacker*, Min. Petr. Mitth., ii., 256, 1879. *Dewalque*, Bull. Soc. Geol. Belg., vi., 150, 151, 1879. As petrifying material, *Genth*, Am. Phil. Soc. Philad., xviii., 259, 1879. A related mineral from Delsbo, Helsingland, *Jolin*, Geol. För. Förh., i., 237, 1873.

Pyrosmalite, Min., p. 414; App. II., p. 46.—Nordmark, anal. and discussion of composition, *Ludwig*, Min. Mitth., 1875, 211. Occurrence at the Kogrufva (formerly Bjelkegrufva), Nordmark, *Sjögren*, Geol. För. Förh., ii., 409, 1875. Dannemora, Sweden, anal., *Engström*, Geol. För. Förh., iii., 116, 1876.

Pyrostilpnite, Min., p. 93.—Probable occurrence at Schemnitz, Hungary, *Becke*, Min. Petr. Mitth., ii., 94, 1879.

A mineral from Chañarcillo, Chili, is described by *Streng* as pyrostilpnite (J. Min., 1878, 917); but *Schrauf* shows that it has the same form as rittingerite, as determined by him (J. Min., 1879, 144), and the true character of it is still in doubt, *Streng*, J. Min., 1879, 547.

Pyroxene, Min., p. 212; App. II., p. 46.—**Cryst.** (augite), Bell, near Laach, *Laspeyres*, Z. Kryst., i., 203, 1877. Nordmark, *Sjögren*, Geol. För. Förh., iv., 364, 1879. Crystallo-genetic observations, *Scharff*, Abhandl. Senck. Nat. Ges., 1874; J. Min., 1876, 168. Containing liquid carbon dioxide (CO_2), *Hartley*, J. Ch. Soc., II., xiv., 137, 237. Containing CO_2 and NaCl, from pegmatite, in Norway, *Helland*, Arch. Math. Nat. Christ., ii., 445, 1877. Middlefield, N. Y., inclosures, *Hirschwald*, J. Min., 1879, 378; *Lewis*, Pr. Ac. Nat. Sc. Phil., 1880, 292. Inclosing much CO_2, Branchville, Conn., and other localities (smoky quartz), *Hawes*, Am. J. Sc., III., xxi., 203, 1881. Analysis of gases in Branchville smoky quartz (CO_2,N,H_2S,SO_2,H_3N,F), *A. W. Wright*, Am. J. Sc., III., xxi., 209, 1881.

Rotatory effect for heat rays of spectrum, *Desains*, C. R., lxxxiv., 1056; same for ultra-violet, *Soret* and *Sarasin*, ib., lxxxiv., 1362. Accurate determination of indices of refraction for different rays, *Sarasin*, C. R., lxxxv., 1230, 1878. Circular polarization for different temperatures, *Joubert*, C. R., lxxxvii., 497, 1878; *Sohncke*, Wied. Ann., iii., 516, 1878; *von Lang*, Pogg. Ann., clvi., 422, 1875. Pyro-electric characters, *Hankel*, Wied. Ann., x., 618. Specific gravity determinations, *Church*, Geol. Mag., II., ii., 321, 1875.

Made artificially, *Hautefeuille*, C. R., lxxxvi., 1133, 1194, 1878; xc., 830, 1880 (Bull. Soc. Min., i., 1, 1878); also *Friedel* and *Sarasin*, Bull. Soc. Min., ii., 113, 1879.

A variety of quartz, having a "peculiar metallic pearly lustre," and forming a coating on ordinary quartz crystals, has been called COTTERITE by *Harkness* (Min. Mag., ii., 82, 1878), from Rockforest, Ireland.

An impure variety of silica, occurring in white earthy masses, is called PASSYITE by *E. Marchand*, Ann. Ch., Phys., V., i., 392, 1874.

RABDIONITE.—App. I., p. 13.

Rabdophane.—See *Rhabdophane*, p. 103.

RAIMONDITE, Min., p. 656.—Optical characters, *Des Cloizeaux*, Bull. Soc. Min., iv., 41, 1881.

RALSTONITE, App. I., p. 13; II., p. 47.—Analogous to garnet in optical character, biax ial, with an angle of 90° (see p. 50), *Bertrand*, Bull. Soc. Min., iv., 34, 1881. According to *Brandl*, quoted by Groth (Tabell. Uebers. Min., p. 42, 126, 1882), the true formula is $3(Na_2,Mg,Ca)F_2 + 8[Al_2]F_6 + 6H_2O$.

Rammelsbergite, Min., p. 77; App. II., p. 47.—**Anal.**, Portezuelo del Carrizo, Dept. of Huasco, Chili, *Domeyko*, Min. Chili, 3d ed., p. 186, 1879.

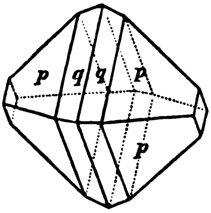
Randite. A canary-yellow incrustation on granite, at Frankford, near Philadelphia, Penn., is described by *König* (Proc. Ac. Nat. Sc. Philad., 1878, 408) as a hydrous carbonate of calcium and uranium. He gives an analysis, made on a very small amount (0·047 gr.) of impure material: [CO_2 29·34], U_2O_3 31·63, CaO 32·50, H_2O 6·53 = 100. *T. D. Rand* (ib., 1880, 274) shows that the coating consists largely of calcite, and after this has been removed by acetic acid, there remain the unattacked tufts of acicular crystals of randite; these, dissolved in hydrochloric acid, yielded largely of calcium and uranium, with a trace of phosphoric acid, alumina, etc. He justly adds, that further investigation is needed to establish the composition of the mineral.

Rauite.—App. II., p. 47.

Realgar, Min., p. 26.—**Cryst.**, Binnenthal, *Groth*, Min.-Samml. Strassburg, p. 20, 1878. *Fletcher*, Phil. Mag., V., ix., 189, 1880.

Occurrence in trachyte, of Tolfa, Rome, Italy, *Sella*, Accad. Linc. Trans., III., i., 66, 1877. In Iron Co., Utah, *W. P. Blake*, Am. J. Sc., III., xxi., 219, 1881.

Reddingite. *G. J. Brush* and *E. S. Dana*, Am. J. Sc., III., xvi., 120, 1878; ibid., xvii., 365, 1879.



Orthorhombic, habit octahedral. Axes, c (vert.) : $\bar{b}$: $\breve{a}$ = 1·0930 : 1·1524 : 1. Observed planes (see figure): 1 (p), 1-$\bar{2}$ (q), i-$\breve{i}$ (b). $I \wedge I$ = 98° 6′, $p \wedge p$ = 114° 44′ and = 103° 10′ (terminal) = 110° 43′ (basal); $q \wedge q$ = 144° 30′. Also granular, massive. Cleavage distinct in one direction. H. = 3–3·5. G. = 3·102. Lustre vitreous to sub-resinous. Color pale rose-pink to yellowish-white, sometimes dark reddish-brown on surface from alteration. Translucent to transparent. Fracture uneven. Brittle. Formula: $Mn_3P_2O_8 + 3aq$. Percentage composition: P_2O_5 34·72, MnO 52·08, H_2O 13·20 = 100. Analyses: 1, H. L. Wells, after deducting 12·08 p. c. quartz; 2, after deducting 4·42 p. c. quartz.

		P_2O_5	FeO	MnO	CaO	Na_2O	H_2O		
1.	(⅔)	34·52	5·43	46·29	0·78	0·31 (Li_2O tr.)	13·08	=	100·41.
2.		35·16	7·89	43·22	0·71	....	12·27	=	99·25.

In the closed tube, first whitens, then turns yellow, and finally brown, but does not become magnetic. Fuses in the naked lamp-flame. B. B. colors the flame pale green, and fuses easily to a blackish-brown non-magnetic globule. Reacts for manganese and iron with the fluxes. Soluble in acids. Occurs sparingly at Branchville, Fairfield Co., Conn., intimately associated with fillowite, fairfieldite, dickinsonite, in a vein of albitic granite. Black octahedral crystals, pseudomorphs after reddingite, are also found. Named from Redding, the name of the town in which the locality is situated.

In crystalline form, reddingite is closely related to scorodite and strengite, but differs from them in composition, containing but three equivalents of water, and having the metals in the protoxide state.

Redonite.—App. I., p. 13.

Reichardtite.—See *Epsomite*, p. 42.

Reinite. *K. v. Fritsch*, Z. gesammt. Nat. III., iii., 864, 1878; *Lüdecke*, J. Min., 1879, 286.

Tetragonal: c (vert.) = 1·279 (approx.). In octahedral crystals, with 1-i as narrow truncation; 1 ∧ 1 = 122° 8′ (basal) = 108° 32′ (pyr.). Cleavage, I, indistinct. H. = 4.

G. = 6·640. Lustre dull, submetallic. Color blackish brown. Streak brown. Opaque. except in the thinnest splinters. Fracture uneven. Analysis, E. Schmidt :

WO_3	FeO	
75·47	24·33	CaO, MgO tr. = 99·80.

Formula : $FeWO_4 = WO_3$ 76·31, FeO 23·68 = 100. Same composition as wolframite, but differs in form ; probably isomorphous with scheelite and wulfenite. B. B. fuses to a dark brown slaggy bead, which is not magnetic. With salt of phosphorus in O. F., brownish red, in R. F., with metallic tin, grayish green. In aqua regia dissolves, with the separation of yellow tungsten trioxide. Occurs with large quartz crystals, from Kimbosan, in Kei, Japan. Named for Prof. Rein, of Marburg, who brought the mineral from Japan. [A pseudomorph?]

REISSITE, App. I., p. 14.—See *Epistilbite*, p. 42.

RESANITE.—App. II., p. 48.

RESIN.—**Anal.**, Greenland, *Chydenius*, Geol. För. Förh., ii., 549, 1875. Oberschlesien, *v. Lasaulx*, Z. Kryst., v., 345, 1881. For various fossil resins, see list on p. xiii,

RESTORMELITE.—App. I., p. 13.

RETINITE. Pitchstone (Des Cloizeaux, Min., p. 346), from Russia, anal., *Pisani*, Bull. Soc. Min., ii., 42, 1879.

RHABDITE. A mineral (anal. by Carnot : Fe 84·28, P 12·10, As 1·65, S 1·75, C tr. = 99·78) formed by combustion in the coal mines of Commentry, France, is referred by *Mallard* (Bull. Soc. Min., iv., 230, 1881) to the meteoric mineral called rhabdite by Rose.

Rhabdophane. *Lettsom*, Z. Kryst., iii., 191, 1878 ; *L. de Boisbaudran*, C. R., lxxxvi., 1028, 1878.

Named from two specimens in the Oxford University collection, which have for fifty years gone by the name of blende, from Cornwall : exact source unknown. By a spectroscopic examination *Lettsom* has found it to give the absorption bands of didymium and erbium, and concludes that it is a phosphate of those bases. *Boisbaudran* remarks that monazite gives the same results with the spectroscope, so that rhabdophane might be a variety of that species. *Bertrand* finds that the mineral is uniaxial and positive (Bull. Soc. Min., iii., 58, 1880) ; an analysis gave : P_2O_5 27·70, $Ce_2O_3(Di_2O_3,La_2O_3)$ 67·20. In optical character, it is shown, consequently, to agree not with monazite, but with cryptolite and phosphocerite (Min., p. 529), with which it has the same composition.

RHAGITE.—App. II., p. 48.

RHODITE.—App. II., p. 48.

RHODOCHROSITE, Min., p. 691 ; App. II., p. 48.—**Cryst.**, Daaden, Rheinprovinz, *Weiss*, ZS. G. Ges., xxxi., 801, 1879. Eleonore mine (Louise mine, according to Seligmann), Horhausen, *Sansoni*, Z. Kryst., v, 250, 1880.

Pseudomorph after alabandite and barite, *Döll*, Verh. G. Reichs., 1875, 95.

Anal., Moët-Fontaine, Ardennes, *de Koninck*, Bull. Ac. Belg., II., xlvii., 568, 1879.

A variety of rhodochrosite has been called MANGANOSIDERITE by *Bayer* (Verh. Nat. Ver. Brünn, xii., May 10, 1873). In appearance it resembles sphærosiderite. An approximate analysis gave: $MnCO_3$ 54·0, $FeCO_3$ 38·8, $CaCO_3$ 6·84, $MgCO_3$ tr., corresponding nearly to $2MnCO_3 + FeCO_3$. From Dobschau, Felsöbanya, Nagybanya, Kapnik, in Hungary.

Deposits of a ferriferous manganese carbonate, at Moët-Fontaine (Rahier), Belgium, are described by *Firket*, Mem. Soc. Geol. Belg., v., 33, 1878 ; Bull. Soc. Geol. Belg., vi., 152, 1879. *Penfield* has analyzed a variety from Branchville, Conn., with 16·76 FeO, Am. J. Sc., III., xviii., 50, 1879. For other intermediate varieties, see *Siderite*, p. 109.

Rhodonite, Min., p. 225.—Cryst., Pajsberg, Sweden (pajsbergite), *Sjögren*, Geol. För. Förh., v., 259, 1881.
Occurrence in the Ural, *Lebedef*, Verh. Min. Ges. St. Pet., II., xiii., 1, 1878.
Anal. (18 p. c. CaO = bustamite), Långban, *Lindström*, Œfv. Ak. Förh. Stockh., xxxv., 6, p. 57, 1880.

A variety of rhodonite from Franklin Furnace, N. J., is called **keatingine** by Shepard (Contrib. Min., 1876), it contains 5·6 p. c. ZnO (= fowlerite).

Rionite.—App. I., p. 14.

Ripidolite, Min., p. 497; App. II., p. 48.—See *Penninite*, p. 90.

Rittingerite, Min., p. 94; App. II., p. 48.—Occurs at Schemnitz, Hungary, *Becke*, Min. Petr. Mitth., ii., 94, 1879.
See also *Pyrostilpnite*, p. 90.

Rivotite.—App. II., p. 48.

Rogersite. *J. L. Smith*, Am. J. Sc., III., xiii., 367, 1877.
Massive. As a thin mammillary crust on samarskite. H. = 3·5. G. = 3·313. Color white. Analyses (stated to be only approximate): 1, Cb_2O_5 18·10, Y_2O_3, etc. 60·12, H_2O 17·41 = 95·63; 2, Cb_2O_5 20·21, H_2O 16·34, Y_2O_3 undet. Considered as a decomposition product of samarskite, with which, and with hatchettolite, it occurs in Mitchell Co., N. C. Named after Prof. Wm. B. Rogers. [Needs further examination.]

Rœmerite, Min., p. 655.—Cryst., *Lüdecke*, Z. gesammt. Nat., III., v., 407, 389, 1880.

Rœpperite.—App. II., p. 49.

Romeite, Min., p. 547.—According to *Bertrand*, the octahedral crystals are formed by the grouping of 8 rhombohedral crystals of 90° about the central point, Bull. Soc. Min., iv., 240, 1881.

Roscoelite. *J. Blake*, Am. J. Sc., III., xii., 31, 1876; *Genth*, ib., p. 32. *H. E. Roscoe*, Proc. Roy. Soc., xxv., 109, 1876. *Genth*, Am. Phil. Soc. Philad., xvii., 119, 1877, or Z. Kryst., ii., 8, 1877.
Micaceous in structure: basal cleavage perfect. Scales minute, often arranged in stellate or fan-shaped groups. Biaxial, acute bisectrix negative, normal to cleavage, $\rho < v$ (Des Cloizeaux, Bull. Soc. Min., i., 51, 1878; iv., 56, 1881).
Soft. G. = 2·902 (Roscoe); 2·921, 2·938, purest (Genth). Lustre pearly, inclining to submetallic. Color dark clove brown to greenish brown, dark brownish green. Analyses: 1, Genth (after deducting 0·85 gold, quartz, etc.); 2, 3, Roscoe.

	SiO_2	V_2O_3	Al_2O_3	Fe_2O_3	Mn_2O_3	FeO	MgO	CaO	Na_2O	K_2O	Li_2O	H_2O
1.	47·69	20·56	14·10	....	....	1·67	2·00	....	0·19	7·59	tr.	4·96 = 98·76
2.	41·25	28·85 V_2O_5	14·34	1·04	1·45	....	1·96	0·61	0·72	8·25		0·94 hygrosc. [water 2·12 = 101·53
3.	....	28·36 V_2O_5	13·94	1·23	0·85	....	2·06	0·62	0·92	8·87		1·22 hygrosc. [water 2·42

In his first paper, Genth gives five other analyses, made on material more or less impure. He also announces the vanadium as present as V_6O_{11} (= $2V_2O_3 + V_2O_5$), but in the later publication regards it possible that it is all V_2O_3; he shows that the mineral is always more or less impure through mechanical admixture, and on this ground questions the correctness of Roscoe's results. Genth deduces the formula $K(Mg,Fe)[Al_2,V_2]_2Si_{12}O_{32} + 4aq$, which requires: SiO_2 49·33, Al_2O_3 14·09, V_2O_3 20·62, FeO 1·64, MgO 1·83, K_2O 7·55, H_2O 4·94 = 100. Roscoe, on the other hand, makes the mineral a vanado-silicate, thus: $4AlVO_4 + K_4Si_9O_{20}$ + aq, which requires: SiO_2 41·18, V_2O_5 27·63, Al_2O_3 15·59, K_2O 14·24, H_2O 1·36 = 100. B. B. fuses easily to a black glass. Gives with salt of phosphorus a dark yellow bead O. F., and an emerald green bead R. F. Only slightly acted upon by acids.

Occurs intimately mixed with gold in seams ($\frac{1}{10}$ to $\frac{1}{20}$ in. thick) in porphyry, and filling cavities in quartz, at the gold mine at Granite Creek, near Coloma, El Dorado Co., California; also from Big Red Ravine, near Sutter's mill, where gold was first discovered in California (*Hanks*, Min. Sc. Press, June 25, 1881). Hanks remarks, that at the Granite Creek locality, some 400 or 500 lbs. of the mineral have been discovered, which were wasted in the extraction of the gold.

Genth also describes (l. c.) a mineral occurring in the Magnolia District, Colorado, as a thin earthy incrustation, of a grayish to olive green color on calaverite, also inclosed in quartz, and giving it a green color. An analysis of the quartz gave: Quartz 79·38, Te 1·05, Au 0·03 = 80·46; the balance (19·5 p. c.) is assumed to belong to the green mineral which forms the coloring matter. An analysis of this, after the deduction of the quartz, gave (mean of 5 partial analyses): SiO_2 56·74, Al_2O_3 19·62, V_2O_3 7·78, FeO 3·84, MgO 2·63, Na_2O 0·94, K_2O 8·11, MnO, Li_2O tr., H_2O undet. = 99·66. Genth regards this as probably closely related to roscoelite, perhaps a variety.

ROSELITE, Min., p. 560; App. II., p. 49.—Analyses by *Winkler*, J. pr. Ch. II., xvi., 86, 1877 (quoted by Weisbach, Jahrb. Berg.-Hüttenwesen, 1877).

	As_2O_5	CoO	CaO	MgO	H_2O		
1.	52·93	10·56	24·93	3·95	8·35	=	100·72.
2	52·41	10·03	25·17	4·22	8·22	=	100·05.

These correspond to the formula: $R_3As_2O_8 + 2aq$ (not 3aq, Schrauf); if Ca : Co : Mg = 10 : 3 : 2, then the formula gives: As_2O_5 52·39, CoO 10·25, CaO 25·51, MgO 3·65, H_2O 8·20 = 100.

Rosterite.—See *Beryl*, p. 18.

ROSTHORNITE.—App. II., p. 49.

Rubislite. *Heddle*, Trans. Soc. Edinb., xxix., 112, 1879.
A dark green compact granular or fine foliated aggregate. G. = 2·44. Analysis: SiO_2 37·85, Al_2O_3 10·92, Fe_2O_3 9·84, FeO 9·01, MnO 0·46, CaO 4·22, MgO 8·00, K_2O 3·33, H_2O 16·13 = 99·76. Completely decomposed by hydrochloric acid. B. B. fuses to a brown slag. From the granite of Rubislaw, near Aberdeen, Scotland. [To be classed with the already too large list of doubtful substances of the so-called "chlorite group."]

RUTILE, Min., p. 159; App. II., p. 49.—**Cryst.**, paramorphs after arkansite (brookite), Magnet Cove, *vom Rath*, J. Min., 1876, 397; pseudomorphs after hematite, Binnenthal, *id.*, Z. Kryst., i., 13, 1877, and eightlings from Magnet Cove, Ark., ibid., p. 15. (Ilmenorutile), Wschiwoi-See, Ilmen Mts., *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xii., 284; xiii., 419; xiv., 239. Associated with magnetite in parallel position, Binnenthal, *Seligmann*, Z. Kryst., i., 340, 1877. In splendent crystals, from Alexander Co., North Carolina, *Hidden*, Am. J. Sc., III., xxi., 159, 1881.

Mallard includes rutile among the pseudo-tetragonal minerals (Ann. Min., VII., x., 134, 1876); see also *Brookite*, p. 18.

As a microscopic constituent of rocks, *Sauer*, J. Min., 1879, 569 (see zircon); 1880, i., 94; 1881, i., 227.

Janovsky (Ber. Ak. Wien, lxxx., 34, 1880) has given the name ISERIT to what he regards as a new titanate. It was found among the black grains of the so-called "iserin" of the Iserwiese, Bohemia. It is distinguished from the true iserin by the absence of conchoidal fracture and the brown color. In thin fragments it is honey yellow. Crystalline form like rutile, occasionally in twins; cleavage imperfect. G. = 4·52. Analysis: TiO_2 70·01 ($\frac{7}{8}$), FeO 28·68 ($\frac{2}{5}$), MnO 1·41, MgO 0·32, Cb_2O_5, SiO_2 0·44 = 99·73, corresponding to the formula: $FeTi_2O_5$. [Groth (Z. Kryst., v., 400) justly remarks that the mineral is not far from the ferruginous rutile called nigrine, and that a more exact determination as to form, homogeneity, etc., is needed to prove its independent character. If it is an independent species the name is an unfortunate one, as tending to confusion with the distinct iserin, also called iserite.]

SAHLITE.—See *Pyroxene*, p. 100.

SAL AMMONIAC.—App. II., p. 49.

SAMARSKITE, Min., p. 520; App. II., p. 49.—**Cryst. description**, Mitchell Co., N. Carolina, *E. S. Dana*, Am. J. Sc., III., xi., 201, 1876.

Analyses, Mitchell Co, N. C.: 1, ***Miss E. H. Swallow***, Proc. Nat. Hist. Bost., xvii., 424, 1875. 2, *O. D. Allen*, Dana's Text-Book Min., 1877, p. 340, and Am. J. Sc., III., xiv., 130, 1877. 3, *J. L. Smith*, Am. J. Sc., III., xiii., 362, 1877. 4, ***Rammelsberg***, ZS. G. Ges., xxix., 817, 1877.

Anal. of Miask samarskite, *Rammelsberg*, ZS. G. Ges., xxix., 817, 1877.

Examination of the earths contained in samarskite from North Carolina: *J. L. Smith* ("mosandrum"), C. R., lxxxvii., 146, 148, 831, 1878. *Delafontaine* (terbium), Bibl. Univ., II., lxi., 273, 1878; *id.* (decipium, phillipium), ib., III., iii., 246, 250, 1880; C. R., xciii., 63, 1881. Same subject discussed by *Marignac*, Bibl. Univ., III., iii., 413, 1880.

Damour (Bull. Ac. St. Pet., xxiii., 463, 1877) shows that the VIETINGHOFITE of v. *Lomonossof* is essentially a ferruginous variety of samarskite. Amorphous. H. = 5·5–6. G. = 5·53. Color black, dull. Streak brown. Lustre submetallic. Easily decomposed by H_2SO_4. An analysis gave: Cb_2O_5 51·00, TiO_2 1·84, ZrO_2 0·96, U_2O_3 8·85, Y_2O_3 6·57, $Ce_2(Di,La)_2O_3$ 1·57, FeO 23·00, MnO 2·67, MgO 0·83, ign. 1·80 = 99·09. Locality near Lake Baikal, in the Ural.

SAPONITE, Min., p. 472; App. II., p. 49.—Analyses, from igneous rocks in Scotland, *Heddle*, Trans. Soc. Edinb., xxix., 91 et seq., 1879. See also *Bowlingite*, p. 17.

Sarawakite. *Frenzel*, Min. Mitth., 1877, 300. Occurs in minute crystals, with many planes and rounded angles, "probably tetragonal." Soft. Lustre adamantine. Colorless or wine yellow to greenish yellow. Transparent. Contains antimony, anhydrous. Found in cavities in the native antimony of Borneo. [Needs further examination. Senarmontite?]

SARCOPSIDE.—App. I., p. 14.

SAUSSURITE.—**Anal.**, Midsåterfjeld, Bergen, Norway, ***Hjortdahl***, Nyt. Mag. Nat., xxiii., 1877. Analyses quoted, and discussion of the relations between the different varieties, *J. D. Dana*, Am. J. Sc., III., xvi., 340, 395, 1878.

SAYNITE.—See *Polydymite*, p. 95.

SCAPOLITE, Min., p. 317; App. II., p. 50.—**Analyses**, Rossie, N. Y., ***Sipöcz***, Min.-Mitth., 1877, 266. Boxborough, Mass., *Becke*, 1877, 267. Various Canadian localities, *F. D. Adams*, Am. J. Sc., III., xvii., 315, 1879. Bamle, Norway, ***Michel-Lévy***, Bull. Soc. Min., i., 43, 1878. Monzoni, *Kiepenheuer*, Ber. nied. Ges. Bonn, Aug. 4, 1879. Malsjö, Arendal, and Gouverneur, *Sipöcz*, Min. Petr. Mitth., iv., 265, 1881.

Adams calls attention to the fact that unaltered scapolite uniformly contains chlorine (up to 2·48 p. c.). The presence of this element is also shown by Neminar in meionite, and by Sipöcz and Becke (l. c.).

See also *Meionite*, p. 74.

A scapolite from Galway, Ontario Co., Canada, has been called ONTARIOLITE by *C. U. Shepard* (Am. J. Sc., III., xx., 54, 1880). It occurs in prismatic crystals in a limestone; the color is black or gray, from the presence of admixed impurities. The pure portions are transparent and colorless, H. = 7–7·5. [The value of an approximate analysis given is destroyed by the impurity of the material analyzed; thus far it has no claim to be considered an independent species.]

SCHEELITE, Min., p. 605; App. II., p. 50.—Cryst., Untersulzbachthal, etc., *Groth*, Min.-Samml. Strassburg, p. 157, 1878.

Absorption bands in spectrum (Ce, La, Di), *Cossa*, Accad. Linc. Mem., III., iii., 24, 31, 1878.

Occurrence with gold, Charity mine, Warren's, Idaho, and Golden Queen mine, Lake Co., Col., *Silliman*, Am. J. Sc., III., xiii., 451, 1877. From the Victoria Reef mine, Adelong, New South Wales, *Liversidge*, Proc. Roy. Soc. N. S. W., Nov. 3, 1880.

SCACCHITE.—App. II., p. 50.

SCHIRMERITE.—App. II., p. 50.

Schneebergite. *A. Brezina*, Verh. Geol. Reichs., 1880, 318.

Isometric; in small (0·5–1 mm.) octahedrons. Cleavage dodecahedral in traces. H. = 6·5. G. = 4·1 (Weidel). Lustre vitreous to adamantine. Color honey yellow. Transparent. Fracture conchoidal. Brittle. Consists principally (Weidel) of lime and antimony, with a little iron, and traces of copper, bismuth, zinc, magnesia, and sulphuric acid. B. B. infusible, becomes slightly brown. Insoluble in acids. Found by Lhotsky, at Schneeberg, Tyrol, near the union of anhydrite (or gypsum) with chalcopyrite and magnetite. [Needs further examination. Perhaps related to atopite, p. 10.]

SCHORLOMITE, Min., p. 390.—According to *Knop*, does not occur at Oberschaffhausen, in the Kaiserstuhl (Z. Kryst., i., 58, 1877); but the mineral which has received that name is either a titaniferous melanite or pyroxene.

Intimately associated with melanite, Magnet Cove, Ark., *König*, Proc. Acad. N. Sc. Phil., 1876, 36.

Schraufite. *J. von Schröckinger*, Verh. Geol. Reichs., 1875, 134.

A mineral resin occurring in small masses and in layers, in the schistose sandstone (Carpathian sandstone), near Wamma, in Bukowina. H. = 2–3. G. = 1·0–1·12. Color hyacinth to blood red. Translucent. Fracture semi-conchoidal to splintery. Melting point 326°, when decomposition goes on. Partially soluble in alcohol, benzol, and chloroform; completely soluble in sulphuric acid, the larger portion of the resin separating as a grayish-yellow slimy mass, upon dilution with water. Analysis by Dietrich:

C	H	O
73·81	8·82	17·37.

Formula: $C_{11}H_{16}O_2$, requiring: C 73·33, H 8·89, O 17·78 = 100. With this resin correspond also a resin from Mizun and Höflein, and less closely others from the neighborhood of Lemberg. Schröckinger proposes to include the several occurrences under the name Schraufite, after Prof. A. Schrauf, of Vienna. The same resin occurs in the Libanon, according to John (Verh. G. Reichs., 1876, 255); see also *Bronner*, Württ. Nat. Jahresb., xxxiv., 81, 1878.

SCHREIBERSITE.—Min., p. 61; App. II., p. 50.

SCHRÖCKERINGERITE.—App. II., p. 50.

SCHWARTZEMBERGITE, Min., p. 120.—Optically uniaxial, negative, *Bertrand*, Bull. Soc. Min., iv., 87, 1881.

SCOLECITE, Min., p. 428; App. II., p. 50.—Cryst., *Lüdecke* (J. Min., 1880, ii., 200; 1881, ii., 1) distinguishes between the monoclinic (Iceland and Kandallah) and triclinic (from the

Schattige Wichel, Fellinen Alp, Farõe, and Etzlithal) varieties, and makes them isomorphous with similar varieties of mesolite.

Pyro-electrical characters, *Hankel*, Wied. Ann., vi., 56, 1879.

Anal. (Bechi), Casarzia, Liguria, *Issel*, Boll. Com. Geol., 1879, 530. Etzlithal, *Schmid*, Ber. Jenaisch. Ges. Med. Nat., July 9. 1880. Schattige Wichel, Fellinen Alp, *Lüdecke*, J. Min., 1881, ii., 19.

Anal., Distr. Lucma, Peru, *Raimondi*, Min. Pérou, p. 228, 1878.

Made artificially, *Bourgeois* and *Verneuil*, Bull. Soc. Min., iii., 32, 1880.

See also *Strengite* and *Reddingite*.

An earthy mineral, formed from the decomposition of arsenopyrite, and referred to scorodite, has been called JOGYNAITE by *N. v. Nordenskiöld*. Occurs with beryl at Adun-Tschilon, Nertschinsk. See *v. Kokscharof*, Bull. Acad. St. Pet., xix., 571, 1873.

SCOLOPSITE.—See *Ittnerite*, p. 68.

SEEBACHITE, App. II., p. 50.—See *Herschelite*, p. 57.

SELLAITE, App. I., p. 14.—The corresponding compound, MgF_2, made artificially, *Cossa*, Accad. Linc. Mem., III., i., 83, 1876, or Z. Kryst., i., 207, 1877.

Corrections of angles and symbols previously given, *Strüver*, Att. Accad. Torino, xii. 59, 1876.

SELWYNITE, Min., p. 509; App. I., p. 19.—According to a microscopic examination by *Ulrich*, a mixture, consisting of a felsite-like base, with hydrous chromic oxide and occasional octahedrons of chromite, Am. J. Sc., III., xi., 235, 1876.

Semseyite. *Krenner*, Ungar. Revue, 1881, 367. Briefly announced as containing sulphur, antimony, and lead, and related to plagionite, from Wolfsberg, in the Harz. Occurs in gray crystals, with diaphorite, sphalerite, and pyrite, at Felsöbanya.

SENARMONTITE, Min., p. 184.—According to *Mallard* (Ann. Min., VII., x., 108, 1876. pseudo-isometric, the crystals being made up of 48 triclinic individuals. The same subject has been investigated by *A. Grosse-Bohle* (Z. Kryst., v., 222, 1880); he concludes that the species is to be regarded as monoclinic, and the crystals made up of 12 individuals (including those parallel, 24), twinned parallel to *O* and 1; he however suggests, in conclusion, that the optical anomalies may have another explanation, and the mineral still be included in the isometric system. An examination of artificial crystals of arsenolite led to similar results.

SEPIOLITE, Min., p. 456.—A fibrous variety from Utah, analyzed by *Chester*, Am. J. Sc., III., xiii., 296, 1877.

SERICITE, Min., p. 487.—A massive muscovite, as shown by *Laspeyres* (Z. Kryst., iv., 244), who explains the varying results of earlier investigators by the greater or less impurity of the substance examined. He regards it as having owed its origin to the alteration of feldspar. On the sericite from the Taunus, see *Wichmann*, Verh. Nat. Ver. Bonn, xxxiv., 1, 1877.

SERPENTINE, Min., p. 464 ; App. II., p. 51.—Description and analyses : Pusunsaari, *Tagern*, *Schildt*, Œfv. Finsk. Vet. Soc., xvii., 70, 1874–75. Zöblitz, Greifendorf, Waldheim, *Lemberg*, ZS. G. Ges., xxvii., 531, 1875. New Jersey, *Berwerth*, Min. Mitth., 1875, 110. Vosges, *Weigand*, Min. Mitth., 1875, 183. Northern Norway, *Pettersen*, J. Min., 1876, 613. Nordmark, *Lundström*, Geol. För. Förh., iii., 191, 1876. Långban, Wermland (7·3 p. c. MnO), *Paijkull*, Geol. För. Förh., iii., 351, 1877. Verrayes, Val d'Aosta, *Cossa*, Accad. Linc. Mem., III., ii., 933, 1878. Reichenstein, Silesia, *Hare*, Inaug. Diss. Breslau.

1879 (Z. Kryst., iv., 294). Florida, Mass. (picrolite), anal. by Melville, *Wadsworth*, Bost. Soc. Nat. Hist., xx., 286, 1879.

Microscopic examination, metaxoite, picrofluite, *Wiik*, Œfv. Finsk. Vet. Soc., xvii., 8, 1874–75.

A serpentinous mineral is called TOTAIGITE by *Heddle* (Trans. Soc. Edinburgh, xxviii., 455, 497, 1878). It appears as a pseudomorphous substance surrounding malacolite, in a granular limestone; resembles danburite, from Danbury, Ct. Lustre weak. glimmering. Color pale fawn, sometimes blue-black. Cleavage distinct. Fracture conchoidal. Soft. Often surrounded itself by yellow green or dark gray serpentine. Analyses: 1, fawn-colored variety; 2, dark blue variety, on the surface ochre yellow; G. = 2·84–2·893.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	MgO	CaO	Na_2O	K_2O	H_2O		
1.	37·23	0·76	....	1·05	0·23	44·97	5·24	....	....	10·64	=	100·11.
2.	36·19	0·26	0·29	2·96	0·45	45·57	3·27	0·43	0·25	10·20	=	99·87.

Locality Totaig, Ross-shire, Scotland. The author justly does not regard this as in any sense a mineral species [but why should it receive a name?]. Its method of occurrence suggests that it is an intermediate product between the pyroxene and the final serpentine; but the author calls attention to the fact that it contains more magnesia than the last-named species.

Serpierite. *Des Cloizeaux*, Bull. Soc. Min., iv., 89, 1881; *Bertrand*, ib.

Orthorhombic; in minute tabular (*O*) crystals elongated, often grouped in light tufts, and striated in the direction of the shorter diagonal. Observed planes: *O*, *I*, 1, also 1-ĭ, ½-ĭ, probable, and ⅔-ĭ, ⅓-ĭ, $\frac{4}{3}$-ĭ, 8-ĭ, all doubtful. $I \wedge I = 98° 42'$, $O \wedge 1 = 115° 32'$. Optic-axial plane macrodiagonal, bisectrix negative. 2H = 43° 35′–44° 20′, and 2E = 65° 57′–67° 10′, red; dispersion $\rho > \upsilon$. Color greenish bluish. Transparent. In composition, according to Damour, a basic sulphate of copper and zinc. [Needs further examination on the chemical side.] From Laurium, Greece.

Siderazot. *O. Silvestri*, Pogg. Ann., clvii., 165, 1876.

A product of volcanic eruption, observed at Mt. Etna after the eruption of Aug., 1874, as a very thin coating on lava. Non-crystalline. Lustre metallic, resembling steel. Slowly attacked by acids. An analysis gave: Fe 90·86, N 9·14 = 100, which corresponds to Fe_5N_2, or that adopted by Frémy for the artificial iron nitride.

SIDERITE, Min., p. 688; App. II., p. 51.—Anal., San Giovanni, Val d'Arno, Italy, *Grattarola*, Boll. Com. Geol., 1876, 342. Felsőbanya, anal. by Dietrich (27·7–44·4 p. c. $MnCO_3$), Kapnik (3·98 $MnCO_3$), *v. Schröckinger*, Verh. geol. Reichs., 1877, 114. Newburyport, Mass., *Miss E. H. Swallow*, Proc. Bost. Soc. Nat. Hist., xvii., 464, 1875. Earthy variety (amorphous), easily soluble in cold acids, from the Schwelm mine, *Muck*, Z. Berg.-Hütt.-Sal.-Wesen, xxviii., 189, 1880.

Recent formation at Bourbonne-l'Archambault, *Daubrée*, C. R., lxxx., 1300, 1875.

See also *Rhodochrosite*, p. 103, for other intermediate compounds.

Sideronatrite. *Raimondi*, Minéraux du Pérou, p. 212, 233, 1878. *Domeyko*, 3d ed. Min. Chili, p. 158, 1879.

In crystalline masses. H. = 2·5. G. = 2·153. Color dark yellow. Streak pale yellow to yellowish white. Analysis:

SO_3	Fe_2O_3	Na_2O	H_2O
43·26	21·60	15·59	15·35, earthy matter 3·20, NaCl mechanically mixed 1·06 = 100·06.

Formula $Na_2SO_4 + [Fe_2]S_2O_9 + 6aq$. Insoluble in water, but decomposed on heating, with the separation of iron sesquioxide. Soluble in acids. From the mine San Simon, Huantajaya, province of Tarapaca, Peru.

Another sulphate, almost identical with sideronatrite, has been called URUSITE by *A. Frenzel* (Min. Petr. Mitth., ii., 133, 359, 1879). Orthorhombic. Pulverulent, earthy; also in lumps, but consisting of minute prismatic crystals with pinacoids, and also *I*, 1, 1-ĭ and *O*. Soft. G. = 2·22. Color lemon to orange yellow. Streak ochre yellow. Transparent in minute crystals. Calculated formula: $Na_4[Fe_2]S_4O_{17} + 8aq = SO_3$ 42·78, Fe_2O_3 21·39, Na_2O 16·58, H_2O 19·25 = 100. Analyses, 1, 2; 1, after deducting 3 p. c. insoluble:

	SO_3	Fe_2O_3	Na_2O	H_2O		
1.	42·08	21·28	16·50	16·80	=	99·66.
2.	41·64	22·00	17·24	[19·12]	=	100·00.

Insoluble in water, easily soluble in HCl. Decomposed in boiling water, with separation of Fe_2O_3. Found underlying deposits of iron vitriol (melanterite) on the Urus plateau, near Sarakaja, on the naphtha island, Tscheleken, in the Caspian Sea. [Both of the above sulphates are near the uncertain bartholomite of Cleve, App. II., p. 6.]

Sipylite. *J. W. Mallet*, Am. J. Sc., III., xiv., 397, 1877; xxii., 52, 1881.

Tetragonal; in octahedrons. 1 ∧ 1 (pyr.) 100° 45′ = 127° (basal). Cleavage 1, distinct. Usually imperfectly crystalline, or in irregular masses. H. = 6 nearly. G. = 4·89. Lustre resinous and pseudo-metallic. Color brownish black to brownish orange; in splinters red brown. Streak light cinnamon brown to pale gray. Translucent. Fracture uneven, and small conchoidal. Brittle. Analysis by W. G. Brown:

Cb_2O_5	WO_3	SnO_2	ZrO_2	Eb_2O_3	Ce_2O_3	La_2O_3	Di_2O_3	UO	FeO	BeO	MgO	CaO	Na_2O	K_2O	H_2O

[MnO tr., Li_2O tr., F tr. = 100·48.

* With Ta_2O_5 about 2 p. c. † With Y_2O_3 about 1 p. c. ‡ Di_2O_3, tr. § Ce_2O_3, tr.

Taking together the acid oxides of columbium (niobium), tantalum, tungsten, tin, and zirconium as $\overset{v}{M}_2O_5$, and reducing all the basic elements to the form $\overset{''}{R}O$, and neglecting the water, the ratio $RO : M_2O_5 = 221 : 100$ is obtained, which corresponds to the formula: $R_3M_2O_8 + 4R_2M_2O_7$. Mallet prefers to include the water, making the hydrogen basic, and deduces on this supposition the formula: $R_3M_2O_8$. This view, as he shows, is supported by the fact that in form sipylite is very near fergusonite.

B. B. decrepitates, and glows brilliantly, becomes pale greenish yellow and opaque; infusible. In the closed tube gives off acid water. With borax in O. F. gives a yellow bead, pale on cooling; in R. F. assumes a greener tint. Boiled in strong HCl partially dissolves, the solution reacting for zirconium with turmeric paper; when metallic tin is added and the solution diluted, a sapphire blue color is obtained (columbium). Decomposed completely, though slowly, in boiling concentrated sulphuric acid. Occurs sparingly, imbedded in, or more commonly adherent to, masses of allanite and magnetite, at the northwest slope of Little Friar Mountain, Amherst Co., Virginia. Named from *Sipylus*, one of the children of Niobe, in allusion to the names niobium and tantalum.

Delafontaine (C. R., lxxxvii., 933, 1878) states that sipylite contains yttrium, erbium (in small quantities), philippium (see samarskite), and also the ytterbium of Marignac (see gadolinite).

Spodiosite. *H. V. Tiberg*, Geol. För. Förh., i., 84, 1872.
Orthorhombic. In prismatic crystals, flattened parallel the brachypinacoid, with the planes, *i-ĭ*, *I*, 1, 2-ĭ. *I* ∧ *i-ĭ* = 132°, *I* ∧ *I* = 96°, 2-ĭ ∧ 2-ĭ = 83° top. H. = 5. G. = 2·94. Lustre dull porcelain-like, but vitreous. Color ash gray, inclining to brown. Streak white. Fracture uneven. Brittle.
Analysis by C. H. Lundström :

P_2O_5	CaO	F	As_2O_5	CO_2	Cl	Fe_2O_3	Al_2O_3	MnO	MgO	H_2O	insol.	
33·20	49·81	[4·71]*	0·24	3·00	0·12	1·24	1·11	0·55	2·27	2·70	1·15	= 100.

* Including loss [but the analysis should show an excess].

Disregarding the calcium carbonate, the mineral consists essentially of calcium phosphate and calcium fluoride, in the ratio of 5 : 4 or $5Ca_3P_2O_8 + 4CaF_2$; but the analysis hardly gives a definite decision as to the true composition.
B. B. fuses in the thinnest splinters to a white enamel; does not decrepitate. Soluble in HCl and HNO_3; with effervescence. From the Krangrufva, Wermland, Sweden. Named from *σπόδιος*, *ash gray*. [Perhaps a pseudomorph of apatite, after some other mineral.]

SPODUMENE, Min., p. 228.—Analyses: 1, *Pisani*, C. R., lxxxiv., 1509, 1877; 2, 3, *Dölter*, Min. Petr. Mitth., i., 524, 526, 1878; 4, 5, *Julien*, Ann. N. Y. Acad. 3. Brazil	63·34	27·66		1·15	....	0·69	....	7·09	....	0·98	....	= 100·91
4. Goshen, G. = 3·19	63·27	23·73	Fe_2O_3	1·17	0·64	0·11	2·02	6·89	1·45	0·99	0·36	= 100·63
5. Chesterfield, G. = 3·185–3·201	61·86	23·43	Fe_2O_3	2·73	1·04	0·79	1·55	6·99	1·33	0·50	0·46	= 100·68
6. Branchville, G. = 3·193 $(\frac{2}{3})$	64·25	27·20	Fe_2O_3	0·20	....	....	....	7·62	tr.	0·39	0·24	= 99·90
7. Alexander Co., N. C., *Hiddenite*, G. = 3·152–3·189	64·35	28·10	Fe_2O_3	0·25	....	....	....	7·05	....	0·50	0·15	= 100·40
8. Alexander Co., N. C., *Hiddenite*, G. = 3·166	63·95	26·58	Cr_2O_3 0·18	1·11	....	....	....	6·82	0·07	1·54		= 100·25.

All of these analyses correspond more or less closely to the true formula (Dölter) of the species, viz.: $Li_2Al_2Si_4O_{12}$; note the chromium found by Genth in hiddenite (anal. 8).
The variety of spodumene from Alexander Co., N. C. (anal. 7, 8), occurs in prismatic crystals from ½ inch to 3 inches in length. The crystals are often highly modified, showing many planes not before observed on the species; they are often twins; the forms have been described by *E. S. Dana*, Am. J. Sc., III., xxii., 179. Perfectly transparent, and color from pale yellowish green to deep emerald green; those of the latter color are highly valued as gems, having a peculiar brilliancy, as compared with the emerald, in consequence of the pleochroism; the largest stone cut thus far weighs nearly 2¼ carats. They occur in cavities in a gneissoid rock, with emerald (q. v.), quartz, monazite, rutile, mica. The name *hiddenite* was given by Smith, after W. E. Hidden, through whom they have been introduced as gems, and who has succeeded in finding them in place; those first found (by J. A. D. Stephenson) were of a pale yellowish-green color, and were obtained loose in the overlying soil.

The ALTERATION OF SPODUMENE at Goshen and Chesterfield, Mass., has been studied by *Julien*, Ann. N. Y. Acad. Sc., i., 318, 1879; that of the Branchville mineral has been investigated by *G. J. Brush* and *E. S. Dana*, Am. J. Sc., III., xx., 257, 1880 (or Z. Kryst., v., 192).
According to Julien, the Chesterfield crystals are often of immense size, reaching a length of 35 inches, and a diameter of 10 or 11 inches (see above 4, 5, for analyses of unaltered material). Julien describes pseudomorphs after spodumene of cymatolite, of killinite, of muscovite, of albite, of quartz, and of "vein granite." The substance (see below) called cymatolite by Shepard, has a fibrous to wavy structure, silky lustre, white color; H. = 1·5–2; G. = 2·696–2·700. The cymatolite from Goshen was earlier (Eng. Min.

J., xxii., 217) called AGLAITE by the same author. Analyses: 1, Manning Farm, Goshen; 2, Barrus Farm, Goshen; 3, Chesterfield Hollow.

	SiO_2	Al_2O_3	Fe_2O_3	MnO	MgO	CaO	Li_2O	Na_2O	K_2O	H_2O	
1.	58·51	21·80	0·85	0·29	1·44	0·84	0·19	6·88	6·68	2·40*	= 99·88.
2. *Aglaite*	58·11	24·38	1·66	0·18	0·75	0·48	0·09	2·57	8·38	3·01†	= 99·61.
3. (⅔)	58·58	22·28	1·77	0·15	0·45	0·93	0·10	9·08	4·48	2·08‡	= 99·90.

* With nitrogenous organic matter 0·44. † Do. 0·43. ‡ Do. undet.

The killinite has the following characters: H. = 3·5; G. = 2·623–2·652. Lustre dull and greasy to vitreous. Color greenish gray to olive green and greenish black. Analysis, Chesterfield Hollow:

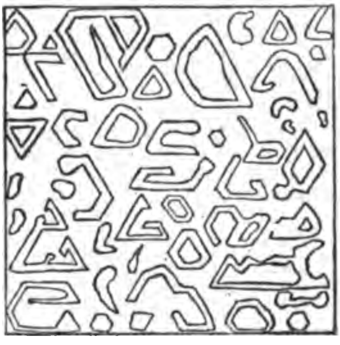
SiO_2	Al_2O_3	FeO	MnO	CoO	MgO	CaO	Li_2O	Na_2O	K_2O	H_2O
46·80	32·52	2·33	0·04	0·04	0·48	0·77	0·82	0·78	7·24	7·66, organic matter 1·14 [= 100·12.

Brush and *Dana* describe, from Branchville, Ct., pseudomorphs after spodumene, of a substance called β spodumene (mixture of albite and eucryptite) of cymatolite (mixture of albite and muscovite), of albite, of microcline, of killinite, of "vein granite." The original crystals of spodumene (now mostly altered) were of great size, sometimes 4 feet long, 12 inches wide, and 2 to 4 inches thick. The unaltered spodumene occurring as a core in many large crystals is transparent, and either colorless or of a fine amethystine purple; for analysis see 6, above.

The first product of the alteration, resulting from the exchange of Na for one-half the Li, is a substance called *β spodumene*. It is compact, apparently homogeneous, with an indistinct fibrous to columnar structure. H. = 5·5–6. G. = 2·644–2·649. Color white, milky, or greenish white. Translucent. Fusibility, 2·25. Three analyses on material from different crystals gave nearly identical results. It is decomposed by HCl into two portions, one soluble and the other insoluble. Analyses by Penfield: 1, of the original material; 2, the soluble portion (32·10 p. c., calculated to 100); 3, insoluble portion (67·56 p. c., calculated to 100):

	SiO_2	Al_2O_3	Li_2O	Na_2O	K_2O	ign.	
1. β spodumene (⅔)	61·51	26·56	3·50	8·14	0·15	0·29	= 100·15.
2. Soluble part	48·13	40·50	10·90	....	0·47	....	= 100.
3. Insoluble part	68·18	20·07	....	11·75	....	....	= 100.

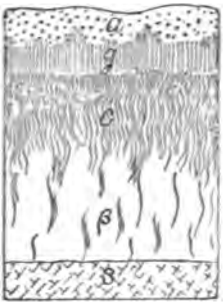
The whole has the composition $(Li,Na)_2Al_2Si_4O_{12}$, or $Li_2Al_2Si_2O_8 + Na_2Al_2Si_6O_{16}$. The insoluble part is albite ($Na_2Al_2Si_6O_{16}$); the soluble portion is a new mineral called *eucryptite* (εὖ, *well*, κρυπτός, *concealed*), and has the composition $Li_2Al_2Si_2O_8$. Examined under the microscope in thin sections (1) parallel to fibres, the irregular interlacing fibres of eucryptite are seen imbedded in albite; (2) transverse to fibres, the eucryptite forms bands with hexagonal outline (see figure), surrounded by albite, like quartz in a "graphic granite." See also *Eucryptite*, p. 44.



The second stage in the alteration is *cymatolite*; it results from β spodumene, by the exchange of K for the remaining Li, that is, the change of eucryptite to muscovite. The cymatolite has a fibrous or wavy structure. G. = 2·692–2·699; color white or slightly pinkish. Two analyses by Penfield, of independent specimens, gave essentially identical results; one of these is:

	SiO_2	Al_2O_3	MnO	Na_2O	K_2O	Li_2O	H_2O	
(⅓)	60·55	26·38	0·07	3·12	8·34	0·17	1·65	= 100·28.

This corresponds to: $(Na,K,H)_2Al_2Si_4O_{12}$, or $(K,H)_2Al_2Si_2O_8 + Na_2Al_2Si_6O_{16}$. The microscopic examination shows that cymatolite is not, as previously assumed, a simple mineral, but, corresponding to the formula, a very uniform mechanical mixture of *muscovite* and *albite*. In some sections the transitions from β spodumene to cymatolite, *i. e.*, from eucryptite to muscovite, are clearly seen. In other cases the muscovite and albite have each segregated together, so that they are distinct. For example, in the figure, s = unaltered spodumene, $\beta = \beta$ spodumene, c = cymatolite, g = mica, a = albite.



As further steps in the alteration there result: albite, often fibrous, like β spodumene, also muscovite, and granular microcline. Still again pseudomorphs occur of killinite. This often retains the structure of the spodumene. The color is light bluish green, to oil green and dark grass green. Analyses: 1, Penfield, of variety showing prismatic structure; 2, Dewey, of compact variety.

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	CaO	K_2O	Na_2O	Li_2O	H_2O	
1.	48·93	34·72	0·54	0·33	0·64	....	9·64	0·35	....	5·04	= 100·19.
2.	53·47	32·36	0·79	0·42	0·72	0·17	7·68	0·44	0·04	4·07	= 100·16.

The examination of thin sections under the microscope showed a slight want of homogeneity, and also revealed a very fine scaly micaceous structure; the killinite is doubtless to be regarded as an impure compact muscovite, like most other members of the pinite group.

The following scheme explains the above changes of the spodumene, supposing an exchange of the alkali metal:

$$\underset{\text{Spodumene}}{2[Li_2Al_2Si_4O_{12}]} = [\underset{\text{Eucryptite}}{Li_2Al_2Si_2O_8} + \underset{\text{Albite}}{Na_2Al_2Si_6O_{16}}]\ \beta \text{ spodumene.}$$

$$= [\underset{\text{Muscovite}}{(K,H)_2Al_2Si_2O_8} + \underset{\text{Albite}}{Na_2Al_2Si_6O_{16}}] \text{ cymatolite.}$$

$$= \underset{\substack{\text{Muscovite} \\ \text{(or killinite.)}}}{(K,H)_2Al_2Si_2O_8} + \begin{cases} Na_2Al_2Si_6O_{16} \text{ albite,} \\ \text{or } K_2Al_2Si_6O_{16} \text{ microcline.} \end{cases}$$

STANNITE.—Min., p. 68; App. II., p. 52.

STAUROLITE, Min., p. 388; App. II., p. 52.—**Cryst.**, *v. Kokscharof*, Min. Russl., vii., 159, 1875; viii., 110, 1881.

New twins and drillings, Fannin Co., Ga., *E. S. Dana*, Am. J. Sc., III., xi., 384, 1875.

A related mineral is called XANTHOLITE by *Heddle* (Min. Mag., iii., 59, 1879). In rough nodular crystals (monoclinic ?), imbedded in biotite. Cleavage in one direction distinct. H. = 6·7. Lustre vitreous to pearly. Color yellowish brown. Fracture conchoidal. Analysis:

	SiO_2	Al_2O_3	Fe_2O_3	FeO	MnO	CaO	MgO	H_2O	F	
$(\frac{2}{3})$	27·12	45·91	8·64	6·91	0·53	3·67	4·41	2·88	0·09	= 100·16.

The material analyzed was not free from biotite. The larger crystals often contain small imbedded crystals, with one perfect cleavage, and of a dark green color, which, it is thought, may perhaps be the same mineral. Found with wollastonite, garnet, and zircon, near Milltown, Loch Ness, Scotland.

[The composition of the mineral, as remarked by Heddle, is essentially that of staurolite, and as the want of perfect homogeneity in the material analyzed is admitted, and as staurolite is a species which is conspicuous for its inclosing impurities, no good reason can be given for separating this mineral from it. It does not deserve a name.]

Steatargillite. *E. E. Schmid*, Ber. Med.-Nat. Ges. Jena, July 9, 1880. A doubtful substance, filling, with quartz and ferrite, the small amygdaloidal cavities in the porphyritic rocks of the Höllekopf, at Kammerberg, and of the Tragberg, at Langewiesen, near Ilmenau. Massive, earthy. H. = 1·25. G. = 2·29–2·46. Color white to light green. Feel greasy. B. B. fuses to a greenish gray black specked enamel; yields much water in the tube, becoming black, and giving a bituminous odor. Analyses: 1, green, Höllekopf (insol. 6 p. c.); 2, green, Tragberg; 3, white, Höllekopf (insol. about 2 p. c.):

	SiO_2	Fe_2O_3	Al_2O_3	FeO	MgO	CaO	H_2O	
1. G. = 2·287	37·20	25·56	8·09	3·78	15·56	0·98	8·70*	= 99·86.
2. G. = 2·465	32·77	17·78	11·12	12·51	14·19	0·91	9·77†	= 99·00.
3. G. = 2·307	38·67	24·72	10·69	0·95	12·95	1·36	9·65‡	= 98·99.

* In vacuo, at ordinary temperature 1·91; at 100° 3·90. † Do. 4·55, 2·52. ‡ Do. 0·70, 7·27.

[The author justly remarks that the material analyzed was not homogeneous. This is not a mineral species. Compare delessite, hullite (this App., p. 60), etc.]

Steeleite.—See *Mordenite*, p. 83.

STEPHANITE, Min., p. 106; App. II., p. 53.—Cryst., Freiberg, Saxony, *Groth*, Min.-Samml. Strassburg, p. 69, 1878. Przibram, *Vrba*, Z. Kryst., v., 418, 1881.
Anal., Przibram, *Kolar*, Z. Kryst., v., 435, 1881.

STERCORITE, Min., p. 551.—**Anal.**, Guañape Islands, *Raimondi*, Min. Pérou, p. 28, 1878.

STERLINGITE.—App. II., p. 53 (15).

STERNBERGITE, Min., p. 54.—Recent analyses of minerals identical with or closely related to sternbergite: 1, Joachimsthal, Rammelsberg, Min. Chem. 2d ed., p. 66, 1875; 2, Andreasberg, Streng, J. Min., 1878, 794; 3, Joachimsthal, Janovsky, Z. Kryst., iii., 187, 1878; 4, Freiberg (argyropyrite of Weisbach, see below), Winkler, Jahrb. Berg.-Hütt., 1878; 5, 6, Joachimsthal (frieseite of Vrba, see below), Preis, Z. Kryst., iii., 187, 1878.

	S	Ag	Fe
1.	29·10	35·27	35·97 = 100·34.
2.	30·71	32·80	35·89, Cu 0·19 = 99·74.
3.	33·14	30·03	34·67, SiO_2 1·32 = 99·16.
4. *Argyropyrite*, G. = 4·206	32·81	29·75	36·28 = 98·84.
5. *Frieseite*	33·0	29·1	37·4 = 99·5.
6. *Frieseite*	33·9	27·6	37·3 = 98·8.

To the above analyses, which show a continual increase in sulphur and iron, and a corresponding decrease in silver, Vrba (Z. Kryst., iii., 186) adds the *argentopyrite* of v. Waltershausen, which gave him S 34·2, Ag 26·5, Fe 39·3; Schrauf (Ber. Ak. Wien, lxiv., 192, 1871) has shown that this is not a pseudomorph (Min., p. 39), but an independent species (G. = 5·53) isomorphous with sternbergite. According to Streng (J. Min., 1878, 785), who describes crystals of "Silberkies" from Andreasberg (anal. 2 above), the composition of the above series of minerals may be expressed by the general formula $Ag_2S + pFe_nS_{n+1}$, of which the first member is acanthite, and the second pyrrhotite; on the ground of this relation he is led to suggest that the latter mineral may be only pseudo-hexagonal (orthorhombic), and then it would be isomorphous with acanthite. Vrba regards this suggestion as not improbable.

Weisbach's argyropyrite (anal. 4, above) occurs at the Himmelfürst mine, at Freiberg, in small crystals, orthorhombic but pseudo-hexagonal, through twinning. Cleavage basal, perfect. H. = 2. G. = 4·206. Color on fresh fracture yellow bronze. Not brittle. Weisbach also found smaller crystals of similar form and color at Marienberg. H. = 4 G. = 4·06–4·12. Brittle.

Vrba's frieseite (anal. 5, 6, above) is from Joachimsthal, Bohemia. In small, thick, tabular, and rectangular crystals; orthorhombic, and very near sternbergite in angle, also similarly twinned parallel I($I \wedge I = 118° 20'$). Cleavage basal, perfect. In thin laminæ, flexible. Color pinchbeck brown to blackish brown. In very thin plates dark greenish gray, translucent. H. about 2. G. = 4·217. Associated with dolomite, smaltite, pyrrhotite, proustite, rittingerite. Z. Kryst., ii., 153, 1878; iii., 186, 1878; v., 426, 1881.

Stetefeldtite.—Min., p. 188; App. II., p. 53.

Stibianite. *E. Goldsmith*, Proc. Acad. Nat. Sc. Philad., 1878, 154.
An alteration product of stibnite, from Victoria, Australia. Massive, porous. Color reddish yellow, of powder pale yellow. Lustre dull. H. = 5. G. = 3·67. Analysis by W. H. Dougherty (l. c.): Sb_2O_5 81·21, H_2O 4·46, gangue 13·55. After deduction of the impurities: Sb_2O_5 94·79, H_2O 5·21 = 100, which corresponds to the formula $Sb_2O_5 + H_2O$. [So obviously impure a material cannot rank as a species. It is near stibiconite, but, according to Goldsmith, contains only Sb_2O_5.]

Stibiconite, Min., p. 188.—**Anal.** (by Santos) of a related mineral from Sevier Co., Arkansas, *Mallet*, Chem. News, xxxvi., 167, 1877. Borneo, *Frenzel*, Min. Mitth., 1877, 298. Chayramonte, Cajamarca, Peru, *Raimondi*, Min. Pérou, p. 196, 1878.

Stirlingite.—App. II., p. 53 (49).

Strengite. *A. Nies*, J. Min., 1877, 8; *G. A. König*, Proc. Acad. Nat. Sc. Philad., 1877, 277.
Orthorhombic. Observed planes, $i\text{-}\breve{i}$, $i\text{-}\breve{2}$, 1. Axes, c (vert.) : $\breve{b}$: $\bar{a}$ = 1·1224 : 1·1855 : 1. $i\text{-}\breve{2} \wedge i\text{-}\breve{2} = 118° 51'$, $i\text{-}\breve{i} \wedge 1 = 129° 11'$, $1 \wedge 1 = 101° 38'$ and 115° 36′ (terminal) = 111° 30′ (basal). Cleavage $i\text{-}\breve{i}$, imperfect. Crystals rare; in habit and angle near scorodite. Generally in spherical and botryoidal forms, aggregates with radiated fibrous structure, and drusy surface. H. = 3–4. G. = 2·87. Lustre vitreous, brilliant. Color peach-blossom red, carmine red, and various other shades; sometimes nearly colorless. Streak yellowish white. Translucent to transparent. Analyses: 1, Nies, after deducting 0·15 insol.; 2, König.

	P_2O_5	Fe_2O_3	H_2O		
1. Eleonore Mine	37·42	43·18	19·40	=	100.
2. Rockbridge Co.	39·30	42·30	19·87	=	101·47.

Formula $[Fe_2]P_2O_8 + 4aq$, which requires: P_2O_5 37·97, Fe_2O_3 42·78, H_2O 19·25 = 100. The mineral is isomorphous with scorodite, and closely related in composition to barrandite. In form also near reddingite. B. B. fuses readily to a black shining bead, coloring the flame bluish green. Iron reaction with borax. Dissolves easily in warm HCl; in HNO_3 insoluble.

Occurs with cacoxenite, at the Eleonore iron mine, near Giessen; also in colorless crystals with eleonorite, at the Rothläufchen mine, near Waldgirmes, in the same region. In distinct crystals, pink to red, in cavities in dufrenite, from Rockbridge Co., Va.; the crystals are different in habit from those described by Nies, and allow of only approximate measurements. Named after Prof. A. Streng, of Giessen.

STRIGOVITE.—App. II., p. 53.

STROMEYERITE.—Min., p. 54; App. II., p. 54.

STRONTIANITE, Min., p. 699; App. II., p. 54.—**Cryst.** description, new forms, twins like aragonite, Hamm, Westphalia, *Laspeyres*, Verh. Nat. Ver. Bonn, xxxiii., 308, 1876. Mifflin Co., Penn., *H. C. Lewis*, Proc. Ac. Nat. Sc. Phil., 1876, 11.

STRUVITE, Min., p. 551; App. II., p. 54.—**Cryst.**, *Sadebeck*, Min. Mitth., 1877, 113, 221; *vom Rath*, Ber. nied. Ges. Bonn, Jan. 7, 1878; **anal.** by *Mac Ivor*, ib., Jan. 13, 1879.

Stützite. *Schrauf*, Z. Kryst., ii., 245, 1878.

Monoclinic, with pseudo-hexagonal symmetry (clino-hexagonal). Crystals highly modified, 39 occurring planes; vertically striated in prismatic zone. Isomorphous with dyscrasite and chalcocite, and in form near jordanite. Lustre metallic. Color lead gray, with reddish tinge. Streak blackish lead gray. Fracture uneven to subconchoidal.

Composition uncertain, perhaps Ag_4Te, requiring Te 22·5, Ag 77·5 = 100. The silver percentage determined approximately with the blowpipe = 72 p. c. (1), = 77 p. c. (2). Easily fusible to a dark bead, from which a silver globule is obtained by reduction with soda.

Identified on a single specimen in the collection of the Vienna University; locality probably Nagyag, Transylvania. Associated with gold and hessite on quartz. Named after Stütz, who, in 1803, described a tellurium mineral from Nagyag, which was probably identical with this, and called it tellursilberblende.

STYPTICITE.—See *Fibroferrite*, p. 47.

Subdelessite.—See *Delessite*, p. 36.

Sulfuricin.—See *Melanophlogite*, p. 74.

Sulfatallophane.—See *Allophane*, p. 3.

SULPHATITE.—Min., p. 614; App. II., p. 54.

SULPHUR, Min., p. 20; App. II., p. 54.—**Cryst.**, *v. Kokscharof*, Min. Russl., vi., 368, 1874. *vom Rath*, Pogg. Ann., clv., 41, 1875. Sicily, *v. Zepharovich*, *Lotos*, 1876 (J. Min., 1876, 561); *Groth*, Min.-Samml. Strassburg, p. 8, 262, 1878; *Fletcher*, Phil. Mag., V., ix., 186, 1880.

SUSANNITE, Min., p. 626; App. II., p. 54.—See *Leadhillite*, p. 67.

SYLVANITE, Min., p. 81; App. II., p. 54.—**Cryst.** discussion of the system (monoclinic), *Schrauf*, Z. Kryst., ii., 211, 1878.

Anal., Grand View mine, Colorado, *F. W. Clarke*, Am. J. Sc., III., xiv., 286, 1877. Smuggler mine, Col., *Jennings*, Trans. Am. Inst. Min. Eng., vi., 507, 1877.

SYLVITE, Min., p. 111; App. II., p. 54.—Vesuvius, *Scacchi*, Att. Accad. Napoli, vi., 1873 (Contrib. Min., II., 23). A salt from Vesuvius, yielded *W. Smith*, KCl 67·13, NaCl 31·01, K_2SO_4 1·86 = 100, Ch. News, xxxvi., 57, 1877.

SYNGENITE.—App. II., p. 54.

Szaboite. *A. Koch*, Min. Petr. Mitth., i, 79, 350, 1878; *von Lasaulx*, Z. Kryst., iii., 288, 1879; *Gonnard*, Bull. Soc. Min., ii, 150, 184, 1879.

Triclinic; in minute (1 mm. long, ·5 broad) thin tabular (*i-ī*) prismatic crystals, terminated at one extremity and vertically striated; also acicular. $I \wedge I' = 87° 15'$, $i\text{-}ī \wedge I = 133° 34'$. H. = 6–7. G. = 3·505. Lustre vitreous; on some planes tending to metallic and pearly. Color hair brown; in thinnest translucent crystals brownish red, hyacinth red. Streak tending to copper red. Translucent to opaque. Analysis:

SiO_2	Fe_2O_3(Al_2O_3 tr.)	CaO(MgO tr.)	Na_2O	ign.		
52·35	44·70	3·12	tr.	0·40	=	100·57.

The calculated formula is $Ca_2[Fe_2]_{11}Si_{35}O_{105}$, or $RSiO_3$; but v. Lasaulx remarks that the iron is probably mostly present as FeO. B. B. fuses with difficulty; with borax an iron bead. Partially decomposed by HCl. Related in composition to babingtonite, and in form to the pyroxene group; most closely to rhodonite.

Occurs with pseudobrookite (q. v.) and tridymite, in cavities in the andesite of the Aranyer Berg, Transylvania. Also on Mte. Calvario (Etna), near Biancaville, Sicily; also Riveau-Grand, Monte Dore. Named after Prof. J. Szabó, of Budapest.

Szmikite. *T. von Schröckinger*, Verh. Geol. Reichs., 1877, 115.

Amorphous, stalactitic, with botryoidal surface. H. = 1·5. G. = 3·15. Color whitish, on the fracture reddish white to rose red. Fracture earthy, splintery. Analyses: 1, Schrauf; 2, Dietrich, gave:

	SO_3	MnO	H_2O		
1.	47·43	41·78	10·92	=	100·13.
2.	47·11	41·61	11·19	=	99·91.

These correspond to the formula: $MnSO_4 + H_2O$, requiring: SO_3 47·43, MnO 42·01, H_2O 10·65 = 100. Exposed to damp air in small fragments becomes deeper red, and increases slightly in weight. From Felsőbanya, Transylvania. Named after Mr. Szmik, Counsellor of Mines.

TACHYLYTE, Min., p. 245.—Occurrence of a similar mineral in the basalt of Royat, Puy-de-Dôme, *Gonnard*, Bull. Soc. Min., iii., 211, 1880.

TALC.—Min., p. 451; App. II., p. 54.

TALCOSITE.—App. I., p. 15.

TAMMITE.—App. II., p. 55.

TANTALITE, Min., p. 514; App. II., p. 55.—From North Carolina, *König*, Proc. Ac. Nat. Sc. Phil., 1876, 39. Coosa Co., Ala., *J. L. Smith*, Am. J. Sc., III., xiv., 323, 1877. Yancey Co., N. C, analysis, *Comstock* (Am. J. Sc., III., xix., 131, 1880): $(\frac{3}{2})$ Ta_2O_5 59·92, Cb_2O_5 23·63, FeO 12·86, MnO 3·06, MgO 0·34 = 99·81. Massive. G. = 6·88.

See also *Columbite*, p. 29.

A manganesian variety is called MANGANTANTALITE by *A. E. Nordenskiöld* (Geol.För. Förh., iii., 284, 1877). In orthorhombic (?) crystals. Cleavage in one direction distinct, in two others less so; the last make with each other and with the first-named nearly right angles. H. = 5·5–6. G. = 6·3. Lustre vitreous. Color reddish to blackish brown; by transmitted light a fine red.

Composition given by the (approximate) analysis: Ta_2O_5(Cb_2O_5) 85·5, MnO 9·5, FeO 3·6, CaO 1·2 = 99·8. Formula, (Mn,Ca,Fe)Ta_2O_6, which requires: Ta_2O_5 86·43, MnO 9·01, FeO 3·42, CaO 1·14 = 100. B. B. unaltered: gives a clear bead with salt of phosphorus; with soda a manganese reaction. Occurs with tourmaline, petalite, lepidolite, microlite, at Utö, Sweden. [The specific gravity leaves little doubt that the mineral contains considerable columbic acid (say 80 p. c.), and is to be considered as a mere variety of tantalite or columbite. Compare the manganese columbite of Branchville, p. 29.]

TAPALPITE.—App. II., p. 55.

TAPIOLITE.—Min., p. 518; App. II., p. 55.

Tarapacaite. *Raimondi*, Minéraux du Pérou, p. 274, 1878. Occurs in minute fragments of a brilliant yellow color, in the midst of soda nitre (caliche). Essentially a potassium chromate, but mixed with a little sodium chloride, sodium nitrate, and sodium and potassium sulphates. From the province of Tarapaca, Peru ; also (Domeyko, Min. Chili, 3d ed., 447) in the natural salt deposits of the desert of Atacama, Chili. [Needs further examination.]

Taznite. *Domeyko*, C. R , lxxxv., 977, 1877; Min. Chili, 3d ed., p. 298, 1879.

Amorphous, more or less fibrous in structure. Earthy. Color yellow. Soluble in hydrochloric acid. Regarded as an arsenio-antimonate of bismuth, analogous to bindheimite, and believed to have been derived from the alteration of some sulpharsenite or antimonate of bismuth. Very impure, from the admixture of varying quantities of bismuth ochre. An analysis gave: Bi_2O_3 (sol. in HNO_3) 42·00, Bi_2O_3 (united with Sb and As) 29·50, Sb_2O_5 5·29, As_2O_5 12·20, Fe_2O_3 7·00, H_2O 4·90, insol. 1·00 = 101·89. A second analysis gave: Bi_2O_3 51·35, Sb_2O_5 11·17, As_2O_5 16·54, Fe_2O_3 8·70. H_2O 4·54, insol. (silicates) 12·50 = 98·80. Obtained with other bismuth minerals from the mines of Tazna and of Choroloque, in Bolivia. [A heterogeneous substance.]

Telaspyrine. *C. U. Shepard*, Contrib. Min., 1877. Pyrite containing tellurium, from Sunshine Camp, Colorado.

TELLURITE, Min., p. 188.—In cracks in native tellurium, at the Keystone, Smuggler mines, and as an incrustation at the John Jay mine, Colorado. In minute prismatic crystals. Cleavable in one direction. Yellow to white. Composition, TeO_2. *Genth*, Am. Phil. Soc. Philad., xvii., 118, 1877.

TELLURIUM, Min., p. 19 ; App. II., p. 55.—From various mines in Bowlder County, Colorado, *Genth*, Am. Phil. Soc. Philad., xvii., 118, 1877.

Genth describes a peculiar variety from the Mountain Lion mine, which Berdell has called LIONITE. It occurs in thin plates. H. = 3. G. = 4·005. Color dark gray. Apparently homogeneous in appearance, but in fact containing 36 p. c. SiO_2 and 6 p.c. Al_2O_3 (Fe_2O_3).

TENNANTITE, Min., p. 104.—**Anal.**, Wilhelmine mine, Seilauf, in the Spessart, *Petersen*, J. Min., 1881, i., 262.

Sandbergerite, from several localities in Peru, *Raimondi*, Min. Pérou, p. 115 et seq., 1878.

A variety of tennantite is called FREDRICITE by *H. Sjögren* (Geol. För. Förh., v., 82, 1880). Massive, compact. H. = 3·5. G. = 4·65. Lustre brilliant, metallic. Color and streak iron black ; sometimes superficially tarnished green, red, brown. Opaque. Fracture uneven. Brittle. **Analysis:**

S	As	Sb	Sn	Cu	Pb	Ag	Fe	
27·18	17·11	tr.	1·41	43·23	3·34	2·87	6·02	= 100·16.

Formula approximately 4RS, As_2S_3, or that of tennantite, with, however, the unusual constituents, lead, tin, and silver. It also differs from tennantite in color and texture. B. B. decrepitates and fuses easily to a black shining mass, which gives a copper bead with soda. In the closed tube gives a sublimate of arsenic trisulphide. Attacked slightly by HCl; decomposed by strong HNO_3, with the separation of lead sulphide and arsenic trioxide. Occurs in small masses imbedded in geocronite. Associated with galenite at Falu, Sweden.

TENORITE, Min., p. 136.—Triclinic, according to *Kalkowsky*, chiefly on optical grounds Z. Kryst., iii., 279, 1879.

A product of the alteration of tenorite is called ATELINA (atelite) by *Scacchi* (Att. Accad. Napoli, vi., Dec. 13, 1873). Observed as more or less complete pseudomorphs after tenorite, and formed by the action on the latter of hydrochloric acid; as a result the black color is changed to green. An analysis gave: CuO 45·59, $CuCl_2$ 38·19, H_2O and loss 16·22 = 100. This corresponds to $2CuO + CuCl_2 + 3H_2O$, or $CuCl_2 + 2(H_2CuO_2) + H_2O$, which requires: CuO 45·76, $CuCl_2$ 38·68, H_2O 15·56 = 100. Found at Mt. Vesuvius, as a result of the eruption of April, 1872. [Not far from atacamite.]

TEPHROITE, Min., p. 259; App. II., p. 55.—**Anal.**, Långban, Sweden, *Pisani*, C. R., lxxxiv., 1511, 1877. An analysis of picrotephroite, from Långban, Wermland, Sweden, gave *S. R. Paijkull:* SiO_2 33·70, MnO 51·19, CaO 0·95, MgO 12·17, ign. 0·44 = 98·45; Geol. För. Förh., iii., 351, 1877.

TEQUEZQUITE. Corruption of Tequixquitl, a mineral substance formed of mixtures of different salts, especially sodium carbonate, and sodium chloride; from Texcoco, Zumpango, in the Valle de Mexico, and elsewhere in Mexico. Naturaleza, iii., 239–246, 1875.

TETRADYMITE.—Min., p. 30; App. II., p. 55.

TETRAHEDRITE, Min., p. 108; App. II., p. 55.—**Cryst.**, twins, *Kopp*, J. Min., 1877, 62. Horhausen, *Seligmann*, Z. Kryst., i., 335, 1877; *Groth*, Min.-Samml. Strassburg, p. 66, 1878. Horhausen, *vom Rath*, Z. Kryst., v., 258, 1880.

Analyses, Newburyport, Mass., *Miss E. H. Swallow*, Proc. Bost. Nat. Hist. Soc., xvii., 465, 1875. Clara mine, Schappbachthal, *Mutschler*, Ann. Ch. Pharm., clxxxv., 296 Gårdsjön, Wermland (aphtonite), *Nilson*, Z. Kryst., i., 417, 1877. Kahl, near Biber, Hesse, with Co 0·50, As 2·6, *Mutschler*, Jahrb. Min., 1877, 275. Brixlegg, Tyrol, *Untchj* and *Becke*, Min. Mitth., 1877, 273, 274. Huallanca, Peru, occurrence described, *H. Sewell*, Am. J. Sc., III., xv., 317, 1877; anal. by *Comstock*, ibid., xvii., 401, 1869. Hungary, *Hidegh*, Min. Mitth., ii., 350, 1879. Mine d'Araqueda, Cajabamba, Peru, *Raimondi*, Min. Pérou, p. 114, 1878. Arizona (16·23 Pb), *Clarke* and *Owens*, Am. Chem. Journ., ii., 173, 1880.

Recent formation at Bourbonne-les-Bains, *Daubrée*, C. R., lxxx., 463, 1875.

A variety is called MALINOFSKITE by *Raimondi* (Domeyko, 5th Append. Min. Chili, 1878: also Raimondi, Min. Pérou, p. 122, 1878). Occurs massive. Color gray with a metallic lustre. An analysis gave: S 24·27, Sb 24·74, As 0·56, Pb 13·08, Cu 14·37, Ag 11·92, Fe 9·12, Zn 1·92 = 100. Remarkable for its high percentage of lead. From the mines of Carpa and Llaccha (above anal.), district of Recuay, Peru.

Another mineral, near tetrahedrite, is called FRIGIDITE by *A. D'Achiardi*. Rarely crystallized; generally granular, compact, massive, with a subconchoidal structure. H. = 4. G. = 4·8. Lustre metallic. Color grayish steel. Powder grayish black. B. B. fuses easily, yielding copious antimonial fumes. Analysis by A. Funaro:

S	Sb	Cu	Fe	Ni	Ag	Zn	SiO_2		
29·60	25·59	19·32	12·67	7·55	0·04	tr.	2·20	=	96·97.

This does not correspond very closely with ordinary tetrahedrite, nor with the mineral called COPPITE by *Becchi*, from this same locality, and for which he obtained: S 27·01, Sb 29·61, Cu 30·10, Fe 13·08 = 99·80 (referred to tetrahedrite by D'Achiardi, Min. Tosc., ii., 341, 1873). [In view, however, of the incompleteness of Funaro's analysis (3 p. c. loss, 2 p. c. gangue), the calculation of a formula has but little value.] From the mines in the Valle del Frigido, Apuan Alps.

Thaumasite. *Nordenskiöld*, C. R., lxxxvii., 314, 1878; *Lindström*, Œfv. Ak. Stockh., Nov. 13, 1878.

Massive, compact. H. = 3·5. G. = 1·877. Lustre greasy, dull. Color white. Translucent. Fracture subconchoidal. Analyses by Lindström, on material collected, 1, by Polheimer, about 1805; 2, by Nordenskiöld, 1859; and 3, by Engberg, 1878:

	SiO_2	CO_2	SO_3	CaO	H_2O	Al_2O_3	MgO	Na_2O	K_2O	Cl		
1.	9·62	6·90	13·12	27·43	42·16	0·17	tr.	0·18	0·07	0·13	=	99·78.
2.	9·70	6·81	12·59	27·17	41·80	0·17	....	0·07	0·07	0·14	=	98·52.
3.	9·78	6·83	13·34	27·24	42·63	0·18	....	0·07	0·10	0·10	=	100·27.

The formula calculated by Lindström is $CaSiO_3 + CaCO_3 + CaSO_4 + 14aq$, which requires: SiO_2 9·93, CO_2 7·28, SO_3 13·25, CaO 27·82, H_2O 41·72 = 100. B. B. swells up, colors the flame red, but infusible. In salt of phosphorus a skeleton of silica. In the closed tube decrepitates and gives off much water.

Occurs filling cavities and crevices at the Bjelke mine, near Aareskuta, Jemtland, Sweden; at first soft, but hardens on exposure to the air. A fine fibrous chalk-white mineral occurs with it, and is regarded as a decomposition product; H. = 1·5–2·5. Composition: SiO_2 11·85, CO_2 6·86, SO_3 13·31, CaO 25·74, Al_2O_3 (Fe_2O_3) 2·58. Named from θαυμαζω, *to be surprised*, in allusion to the remarkable composition.

Törnebohm (quoted by Lindström) states that the material analyzed was homogeneous under the microscope, having a fibrous structure. Bertrand (Bull. Soc. Min., iii., 159; iv., 8) states that he identified calcite, gypsum, and a third mineral, probably wollastonite, in thaumasite, and hence regards it as a mixture; he states that chemical trials by Damour confirm this conclusion. Nordenskiöld, however (Geol. För. Förh., v., 270, 1880), claims that Bertrand's observations were not made on the pure mineral, and that the mixture proposed would not have the above composition. Finally, Cohen confirms by microscopic examination the essentially homogeneous (J. Min., 1881, ii., 21 ref.) appearance; he separated some gypsum and a carbonate soluble in acetic acid, but does not regard the matter as settled. A further critical examination is needed, in view of the seemingly very improbable composition deduced.

Thenardite, Min., p. 615.—Province of Arequipa, Peru, *Raimondi*, Min. Pérou, p. 287, 1878. Balchaschsee, Central Asia, *vom Rath*, Z. Kryst., iv., 430; Ber. nied. Ges. Bonn, Aug. 4, 1879.

Occurs in large deposits on the Rio Verde, Arizona, *B. Silliman*, Am. J. Sc., III., xxii., 204, 1881. An analysis of this by Dunham gave: (½) SO_3 56·36, Na_2O [43·02], CaO 0·12, MgO 0·02, Cl 0·10, insol. 0·38 = 100.

From Aguas Blancas, Atacama, cryst. anal., *Bärwald*, Z. Kryst., vi., 36, 1881.

Thinolite.—See *Gay-Lussite*, p. 51.

Thomsenolite, Min., p. 129; App. II., p. 55.—See *Pachnolite*, p. 88.

Thomsonite, Min., p. 424; App. II., p. 55.—Cryst. form determined with accuracy. $I \wedge I = 90° 26'$, $\dot{c}$ (vert.) : $\bar{b}$: $\breve{a}$ = 1·0095 : 1 : 0·9925, from Is. Laaven, Langesunfiord, Norway, *Brögger*, Z. Kryst., ii., 289, 1878.

Anal., Grand Marais, Minn., *König*, Nat. Leisure Hour, 1878, No. 8. Monzoni, *John*, Verh. Geol. Reichs., 1875, 305.

Peckham and *Hall* (Am. J. Sc., III., xix., 122, 1880) describe in detail the thomsonite amygdules from the diabase of Grand Marais, Lake Superior. These occur in place, and also as polished pebbles on the shores of the lake. Three varieties are distinguished: I., opaque white, resembling porcelain, with conchoidal or occasionally fibrous structure; II., in spherical or ellipsoidal forms, with fibrous radiated structure; sometimes with several centres, often flesh-red, with zones of green, red, and white; III. (called **lintonite**), structure fine granular, not radiated or crystalline, and of green color; sometimes this variety forms a centre surrounded by either var. I. or II. Hardness of the different forms 5–6. G. = 2·33–2·35; 2·2 in weathered pebbles. Analyses by Miss L. A. Linton: 1, var. I.; 2, var. II.; 3, calculated from 2, on the assumption that the true amount of SiO_2 is 40·45 p. c. (as in 1), the remainder being due to free quartz; 4, var. III.

		SiO_2	Al_2O_3	Fe_2O_3	FeO	CaO	Na_2O	K_2O	H_2O	
1.		½ 40·45	29·50	0·23	....	10·75	4·76	0·36	13·93	= 99·98.
2.		½ 46·03	26·72	0·81	....	9·40	3·76	0·39	12·80	= 99·90.
3.		40·45	29·37	0·88	....	10·43	4·28	0·42	13·93	= 99·76.
4.	*Lintonite.*	40·61	30·21	....	0·40	10·37	4·06	0·49	13·75	= 99·89.

The analyses prove that all the specimens examined are the same species, thomsonite. The polished pebbles are often of great beauty, and are highly valued for ornaments.

Thorite, Min., p. 413; App. II., p. 55.—Arendal, Norway, crystals in form of zircon (pseudomorphs), and analysis, *Nordenskiöld*, Geol. För. Förh., iii., 226, 1876. Hitterö, *Lindström*, ib., v., 500, 1881.

A mineral related to thorite, but differing in the large percentage of uranium present, has been described by Collier (Journ. Am. Ch. Soc., ii., 73, 1880) under the name URANOTHORITE. Massive. H. = 5. G. = 4·126. Lustre resinous to subvitreous. Color dark red brown. Streak yellow brown. Fracture subconchoidal. An analysis by H. B. Parsons yielded:

SiO_2	ThO_2	U_2O_3	Fe_2O_3	Al_2O_3	PbO	CaO	MgO	Na_2O	H_2O	
19·38	52·07	9·96	4·01	0·33	0·40	2·34	0·04	0·11	11·31	= 99·95.

B. B. infusible. From the Champlain iron region, N. Y., exact locality unknown.

THROMBOLITE, Min., p. 562.—*Schrauf* (Z. Kryst., iv., 28, 1879) obtained G. = 3·67, also: CuO 39·44, Fe_2O_3 1·05, H_2O 16·56, Sb_2O_5 6·65, Sb_2O_3 32·52, loss 3·78 = 100. Whether this is a true compound or only a mixture is uncertain; if the former, the mineral belongs with the no less uncertain stetefeldtite, partzite (Min., p. 188) and rivotite (App. II., p. 48).

THURINGITE, Min., p. 507.—Cryst. and anal., Zirmsee, Carinthia, *v. Zepharovich*, Z. Kryst., i., 371, 1877; ii., 195, 1878.

Tincalconite. *C. U. Shepard.* Borax from California, pulverulent and efflorescent, 32 p. c. water, Bull. Soc. Min., i., 144.

TITANITE, Min., p. 383; App. II., p. 55.—Cryst., in mica schist, Lama della Spedalaccio, *Uzielli*, Accad. Linc. Mem., III., i., 158, 1877. Albani Mts., *Strüver*, Z. Kryst., i., 250, 1877. Tyrol, *W. J. Lewis*, Phil. Mag., V., iii., 455, 1877. Zermatt (greenovite), *Hintze*, Z. Kryst., ii., 310, 1878. Finland, *F. J. Wiik*, Z. Kryst., ii., 496; *Groth*, Min.-Samml. Strassburg, p. 252, 1878. Zöptau, *vom Rath*, Z. Kryst., v., 255, 1880. Ilmen Mts., *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xvi., 254, 1881.

Absorption of light measured photometrically, *Pulfrich*, Z. Kryst., vi., 155, 1881.

Optical determination in thin sections of rocks, *Fouqué* and *Lévy*, Ann. Min., VII., xii., 437, 1877.

Anal., Waldheim, Saxony (0·38 Y_2O_3), *Schmöger*, ZS. G. Ges., xxvii., 204, 1875. Grenville, Canada, *Harrington*, Geol. Canada, 1878.

In enormous crystals, with apatite, from Renfrew, Canada, sometimes weighing 72 lbs. (Kunz).

A variety of titanite from Småland, Sweden, is called ALSHEDITE by *C. W. Blomstrand* (Minnesskrift Fys. Sällsk. Lund, 1878, p. 7). Occurs in imperfect crystals, sometimes small, sometimes 1–1·5 in. in length; also massive, imbedded in quartz. Form uncertain, probably similar to titanite (Topsöe); two cleavages inclined 125½°. H. = 3·36. G. = 5. Color pale brown to ash gray. Opaque. B. B. readily fusible to a black bead; soluble in HCl. Analysis: 1, mean of 5 more or less complete analyses; 2, mean of 3 analyses:

	SiO_2	TiO_2	SnO_2	Al_2O_3	Fe_2O_3	Y_2O_3	CaO	MnO	MgO	K_2O, Na_2O	H_2O	
1. (⅘)	28·26	36·61	0·47	3·41	4·25	2·78	21·06	0·98	0·48	0·70	1·20	= 100·17.
2. (⅔)	30·61	35·86	0·38	3·47	3·61	2·57	20·51	0·82	0·32	0·58	1·89	= 100·62.

The mineral consequently falls between titanite and keilhauite, and is not far from grothite, Min., p. 386.

Titanomorphite. *A. von Lasaulx*, J. Min., 1879, 568; Z. Kryst., iv., 162, 1879.

Monoclinic; isomorphous with titanite, with corresponding planes and angles. Usually in granular aggregates, often with fibrous structure, surrounding kernels of rutile, or of rutile and menaccanite (nigrin), or menaccanite alone, from the alteration of which it has arisen. Color white. Optically biaxial (microscope), with interference figures resembling those of titanite ($\rho > v$), 2E = 45°–50°; positive. Analysis by Bettendorff:

TiO_2	CaO	FeO	
74·32	25·27	tr.	= 99·59.

This corresponds to CaTi$_2$O$_5$, or a calcium titanate. B. B. fuses to a gray glass. With salt of phosphorus gives a reaction for titanium; by HCl partially, by H$_2$SO$_4$ completely decomposed.

From the hornblende schists of the "hohe Eule," Lampersdorf, Silesia. Lasaulx regards the white decomposition product of titanic iron, often observed, especially in hornblendic rocks, and called LEUCOXENE by Gümbel, as identical with titanomorphite; this would seem, however, to require further proof. Compare remarks by C. W. Cross, Min. Petr. Mitth., iii., 401, 1880. [According to Groth (Tab. Uebers. Min., p. 118, 1882), *Knop* states that titanomorphite is identical with titanite.]

TOCORNALITE, App. II., p. 56.—Several chloro-iodides of silver and mercury are described by *Domeyko*, 5th App., p. 40, 1876; 6th App., p. 30, 1878; 3d ed. Min. Chili, p. 430 et seq., 1879.

TOPAZ, Min., p. 376; App. II., p. 56.—Cryst., Framont, and optical exam., *Bertrand*, Z. Kryst., i., 297, 1877. Saxony and Bohemia, *Laspeyres*, Z. Kryst., i., 347, 1877. Ilmen Mts., *v. Jeremejef*, Verh. Min. Ges. St. Pet., II., xiii., 416. Durango, Mexico, *Des Cloizeaux*, J. Min., 1878, 40. Russian, *Seligmann*, Z. Kryst., iii., 80, 1878. Mt. Bischof, Victoria, *vom Rath*, Ber. nied. Ges. Bonn, Jan. 13, 1879. Elba, *Corsi*, Z. Kryst., v., 604, 1881.

Pseudo-orthorhombic (monoclinic), according to the view of *Mallard*, Ann. Min., VII., x., 155, 1876.

Crystallogenetic discussion, *Scharff*, J. Min., 1878, 168. Specific gravity determinations, *Church*, Geol. Mag., II., ii., 322, 1875. Inclosures, CO$_2$, etc., *Hartley*, J. Ch. Soc., March, 1877, 241; *Erhard* and *Stelzner*, Min. Petr. Mitth., i., 450, 1878; *A. A. Julien*, J. Amer. Ch. Soc., iii., 41, 1881.

Anal. (pycnite), Cerro del Mercado, Durango, Mexico, *Chrustschoff*, Z. Kryst., iii., 634, 1879. Loss upon ignition, *Rammelsberg*, Wied. Ann., vii., 147, 1879.

Altered to muscovite (damourite), *Frenzel*, Min. Petr. Mitth., iii., 513, 1881. Pyrophysalite altered to massive damourite, Kårarfvet, Fahlun, Sweden, *Atterberg*, Geol. För. Förh., ii., 402, 1875.

TORBANITE, Min., p. 742.—Liversidge describes the so-called "kerosene shale" of New South Wales, and refers it to torbanite; this is the substance called *wollongongite*, which name, however, is not appropriate, as the specimen described came not from Wollongong, but from Hartley, Proc. Roy. Soc. N. S. W., Dec. 8, 1880.

Tobermorite. *Heddle*, Min. Mag., iv., 119, 1880.

Massive, fine granular. G. = 2·423. Color pale pinkish white. Translucent. Analyses: 1, Tobermory; 2, north of Tobermory, toward Bloody Bay.

	SiO$_2$	Al$_2$O$_3$	Fe$_2$O$_3$	FeO	CaO	MgO	K$_2$O	Na$_2$O	H$_2$O	
1.	46·51	2·40	1·14	1·85	33·40	0·47	1·45	0·36	12·61	= 100·19.
2. G. = 2·423	46·62	3·89	0·66	1·08	33·98	....	0·57	0·89	12·11	= 99·81.

Occurs filling cavities in the rocks near Tobermory, Island of Mull. [Very near gyrolite, if not identical with it.]

TORBERNITE.—Min., p. 585; App. II., p. 56.

TOURMALINE, Min., p. 365; App. II., p. 56.—In crystals as an outer shell, enveloping orthoclase, from Port Henry, N. Y., *E. H. Williams*, Am. J. Sc., III., xi., 273, 1876.

Pseudo-rhombohedral, analogous to beryl and apatite, according to the view of *Mallard*, Ann. Min., VII., x., 150, 1876.

Power of conducting heat and electricity, *S. P. Thompson* and *O. J. Lodge*, Phil. Mag., V., viii., 18, 1879; ib., x., 67, 1880; same subject, *Fitzgerald*, Sc. Proc. Dubl. Soc., II., i., 370, 1880. Specific gravity determinations, *Church*, Geol. Mag., II., ii., 322, 1875. Relation of electrical conductivity to absorption of light, with reference to Maxwell's theory, *S. P. Thompson*, Phil. Mag., V., xii., 112, 1881. Absorption of light measured photometrically, *Pulfrich*, Z. Kryst., vi., 151, 1881. Electricity produced by pressure, *Jacques* and *Pierre Curie*, C. R., xcii., 186, 1881.

Anal., in dolomite at Campo Longo, Elba, *Engelmann*, Z. Kryst., ii., 312, 1878.
Occurrence of red and green varieties at Wolkenburg, Saxony, *Credner*, Ber. Ges. Leipzig, ii., 49 (J. Min., 1877, 528). As a contact mineral adjoining a granite vein, Mt Willard, N. H., *Hawes*, Am. J. Sc., III., xxi., 21, 1881.

TRAUTWINITE.—App. II., p. 56.

TRIDYMITE, Min., p. 805; App. II., p. 56.—Pseudo-hexagonal through twinning (triclinic), as shown by an optical examination by *Schuster*, Min. Petr. Mitth., i., 71, 1878, and nearly the same time independently by *v. Lasaulx*, Z. Kryst., ii., 253, 1878.
In white ashes ejected from the island Vulcano, *Baltzer*, ZS. G. Ges., xxvii., 57, 1875.
Made artificially, *Hautefeuille*, C. R., lxxxiii., 1183, 1194, 1878 (Bull. Soc. Min., i., 1, 1878). Found with zinc spinel in a zinc furnace, as products of the alteration of the zinc muffles, *Schulze* and *Stelzner*, J. Min., 1881, i., 121.
See also *Asmanite*, p. 10.

TRINKERITE.—App. I., p. 16.

TRIPHYLITE, Min., p. 541.—**Analyses** by S. L. Penfield: 1, Bodenmais, Bavaria, color light blue, G. = 3·549; 2, Norwich, Mass., color grayish green, G. = 3·534 (Am. J. Sc., III., xvii., 226, 1879); 3, Grafton, N. H., color light blue, G. = 3·52, ib., xiii., 426, 1877.

	P_2O_5	FeO	MnO	CaO	MgO	Li_2O	K_2O	Na_2O	H_2O	gangue		
1. $(\frac{3}{2})$	43·18	36·21	8·96	0·10	0·83	8·15	....	0·26	0·87	0·83	=	99·39.
2. $(\frac{3}{2})$	44·76	26·40	17·84	0·24	0·47	9·36	....	0·35	0·42	....	=	99·84.
3. $(\frac{3}{2})$	44·03	26·23	18·21	0·94	0·59	8·79	0·32	0·12	1·47	....	=	100·70.

These correspond closely to the formula: $\dot{R}\ddot{R}PO_4 = \dot{R}_3PO_4 + \ddot{R}_3P_2O_8$, which is thus proved to be the true composition of the species.

TRIPHYLITE—LITHIOPHILITE. *G. J. Brush* and *E. S. Dana*, Am. J. Sci., III., xvi., 118, 1878; ibid., xviii., 45, 1879.
Orthorhombic. Cleavage: basal highly perfect; brachydiagonal nearly perfect; prismatic interrupted, $I \wedge I = 130°$. Massive. H. = 4·5. G. = 3·424–3·482. Lustre vitreous to resinous. Color, salmon color, honey yellow, yellowish brown, light clove brown. Streak uncolored. Transparent to translucent. Fracture uneven to subconchoidal. Optic-axial plane in the basal section; acute bisectrix, positive, normal to brachypinacoid. Axial angle in oil ($n = 1·47$), 74° 45′ red, 79° 30′ blue. Axial colors, $\breve{a}$ deep pink, c (vert.) pale greenish yellow, $\bar{b}$ faint pink.
Composition: $LiMnPO_4$, or $Li_3PO_4 + Mn_3P_2O_8$, with the manganese partly replaced by iron. Percentage composition: P_2O_5 45·22, MnO 45·22, Li_2O 9·56 = 100. Analyses: 1, H. L. Wells (ib., xvi., 118); 2, S. L. Penfield (ib., xviii., 47):

		P_2O_5	FeO	MnO	Li_2O	Na_2O	H_2O	gangue		
1. G. = 3·478	$(\frac{3}{2})$	44·67	4·02	40·86	8·63	0·14	0·82	0·64	=	99·78, Wells.
2. G. = 3·482	$(\frac{3}{2})$	45·22	13·01	32·02	9·26	0·29	0·17	0·29	=	100·26, Penfield.

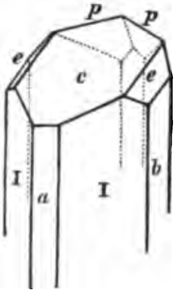
The composition is analogous to that of triphylite (q. v.), of which it is properly a variety peculiar in that it contains mostly manganese in place of iron. In the closed tube gives traces of moisture, turns dark brown and fuses, but does not become magnetic. Fuses in the naked lamp-flame, and B. B. gives an intense lithia-red flame, streaked with pale green on the lower edge. With fluxes reacts for manganese (O. F.) and iron (R. F.). Soluble in acids.
Occurs at Branchville, Fairfield Co., Conn., in a vein of albitic granite. In irregular masses intimately associated with spodumene (and cymatolite, q. v.), also with eosphorite, triploidite, rhodochrosite, uraninite. Named from *lithium* and *φιλός*, *friend*.

At the above locality there is found a large quantity of a black mineral derived from the alteration of lithiophilite, as shown both by its composition and by the fact that it retains more or less of the structure of the original mineral, and sometimes incloses a nucleus of it. It is generally grayish to pitch black, with sometimes a purple or violet tinge. H. = 3–4. G. = 3·26–3·40. Analyses: 1, F. P. Dewey, ib., xvii., 367; 2, H. L. Wells, ib., xvii., 368.

	P_2O_5	Fe_2O_3	Mn_2O_3	MnO	Li_2O	Al_2O_3	CaO	K_2O	Na_2O	H_2O	insol.	
1. G. = 3·395 ($\frac{2}{2}$)	40·66	12·56	25·27	11·66	5·66	0·10	0·18	....	0·49	3·07	....	MgO tr. = 99·65.
2. G. = 3·265 ($\frac{2}{2}$)	40·38	15·89	14·71	18·80	4·83	....	0·72	0·26	tr.	3·37	0·90	= 99·86.

TRIPLITE, Min., p. 543; App. II., p. 56.—From Helsingfors, Finland, *F. J. Wiik*, Œfv. Finsk. Vet. Soc., xvii., 7, 1874–5.

Triploidite. *G. J. Brush* and *E. S. Dana*, Am. J. Sci., xvi., 42, 1878.



Monoclinic. Axes, c (vert.) : b : $\grave{a}$ = 0·80367 : 0·53846 : 1; β = 71° 56. Observed planes (see figure): O (c), i-$\bar{i}$ (b), i-i (a), I, 1-$\bar{i}$ (e), 2-2 (p). $I \wedge I$ = 59° 6′, $c \wedge I$ = 98° 53′, $c \wedge e$ = 125° 12′, $c \wedge p$ = 103° 25′, $a \wedge p$ = 127° 11′. Crystals striated vertically. Commonly in crystalline aggregates, parallel-fibrous to columnar; also divergent, or confusedly fibrous to nearly compact, massive. Cleavage: orthodiagonal perfect.

H. = 4·5–5. G. = 3·697. Lustre vitreous to greasy adamantine. Color yellowish to reddish brown, in isolated crystals also topaz to wine yellow, occasionally hyacinth red. Streak nearly white. Transparent to translucent. Fracture subconchoidal. The axes of elasticity in the clinodiagonal section nearly coincide respectively with the vertical axis (3° to 4° behind), and a normal to the orthopinacoid. No color absorption.

Composition: $R_4P_2O_9, H_2O$ or $R_3P_2O_8 + R(OH)_2$. If R = Mn : Fe = 3 : 1, percentage composition: P_2O_5 31·91, FeO 16·18, MnO 47·86, H_2O 4·05 = 100. Analyses of two varieties by S. L. Penfield:

	P_2O_5	FeO	MnO	CaO	H_2O	
1. ($\frac{2}{2}$)	32·11	14·88	48·45	0·33	4·08	= 99·85.
2	32·24	18·65	42·96	undet.	4·09,	quartz 1·09.

In the closed tube gives off neutral water, turns black and becomes magnetic. Fuses quietly in the naked lamp-flame, and B. B. in the forceps colors the flame green. Reacts for manganese and iron in the fluxes. Soluble in acids.

Occurs at Branchville, Fairfield Co., Conn., intimately associated with eosphorite, dickinsonite, lithiophilite, and other species, in a vein of albitic granite. In crystalline form triploidite is very similar to wagnerite, and as the formulas of the latter species and of triplite are closely analogous ($R_3P_2O_8 + RF_2$), it is concluded that the three species are isomorphous; in triploidite, the hydroxyl (OH) takes the place of the fluorine. Named from triplite and εἶδος, *form*, in allusion to the close similarity between the two species.

Trippkeite. *Damour* and *vom Rath*, Z. Kryst., v., 245, 1880 (or Bull. Soc. Min., iii., 175).

Tetragonal; c (vert.) = 0·9160. Observed planes: O, i-i, I, 1, $\frac{1}{3}$, 3, $\frac{3}{4}$-3, $\frac{3}{2}$-3, $\frac{5}{8}$-$\frac{2}{3}$. Cleavage parallel, i-i perfect, I a little less so (vom Rath). Optically uniaxial, positive (Des Cloizeaux). In small brilliant crystals (1 to 2 mm.), of a bluish-green color.

According to a qualitative examination by Damour, essentially an arsenite of copper (nCuO, As_2O_3). Easily soluble in HNO_3 and HCl. B. B. in the closed tube becomes emerald green on slight heating, then the green disappears and the color becomes brownish; on continued ignition the color becomes yellowish green a second time. Fuses easily to a green slag. In the open tube gives crystals of arsenic trioxide. Occurs with olivenite, as an older formation, in druses in massive cuprite from Copiapo, Chili. Named after the young mineralogist, Dr. Paul Trippke, who died June 16, 1880. [Needs further examination on the chemical side.]

Tritochorite.—See *Eusynchite*, p. 44.

TRITOMITE, Min., p. 412.—Brevig and Barkevig, Norway, complete analyses, *Engström*, Inaug. Diss. Upsala, 1877 (Z. Kryst., iii., 200).

TRÖGERITE.—App. I., p. 16; II., p. 56.

TROILITE, Min., p. 57; App. II., p. 57.—Composition, FeS (not Fe_7S_8, Meunier, App. II., p. 57), according to analyses of *J. Lawrence Smith*, C. R., lxxxi., 976, 1875.

TSCHEFFKINITE.—Min., p. 387; App. II., p. 57.

TSCHERMAKITE, App. II., p. 57.—Conclusion of Hawes, that tschermakite is only an ordinary triclinic feldspar, confirmed by *Bauer*, ZS. G. Ges., xxvii., 235 et seq., 1875.

TURGITE.—Min., p. 167; App. II., p. 57.

TURNERITE.—See *Monazite*, p. 82.

TURQUOIS, Min., p. 580.—Microscopic examination, *Bucking*, Z. Kryst., ii., 163; iii., 81, 1878.

Occurrence in New Mexico, *B. Silliman*, Am. J. Sc., III., xxii., 67, 1881.

Tyreeite. *Heddle*, Min. Mag., iv., 189, 1881. One and a half hundred weight of the carnelian marble of Tyree, Scotland, dissolved in sixteen gallons of dilute HCl left as a residue, thirty pounds sahlite, a little scapolite and titanite, and some ounces of a *red mud*. By decantation, 1·91 grams of a powder of deep brick-red color was obtained. Of this mud sulphuric acid dissolved ·78 gram, leaving 1·13 insoluble. The last was analyzed, and decided to be an impure talc. The soluble portion yielded: Fe_2O_3 38·22, Al_2O_3 8·23, FeO 3·16, MnO 0·39, MgO 29·94. CaO 2·21, H_2O 12·47, P_2O_5 4·71, SiO_2 1·02 = 100·35. To this last obviously heterogeneous substance the new name is provisionally given. [Certainly no name ever given had less claim for recognition in the Science of Mineralogy.]

TYROLITE.—Min., p. 570; App. II., p. 57.

Tysonite. *Allen* and *Comstock*, Am. J. Sc., III., xix., 390, 1880.

Forms the central portion of hexagonal crystals, sometimes an inch or more in diameter, showing the planes *O*, *I*, *i*–2. The crystals are for the most part altered to bastnäsite (see below). Cleavage basal distinct. H. = 4·5–5. G. = 6·12–6·14. Lustre vitreous to resinous. Color pale wax yellow. Streak nearly white. Analyses:

	Ce*	La,Di†	F		
(§)	40·19	30·37	[29·44]	=	100·00.

* Atomic weight 141·2. † Joint atomic weight, specially determined, 138.

This gives the ratio Ce + (La,Di) : F = ·504 : 1·547, corresponding to the formula $(Ce,La,Di)_2F_6$. B. B. blackens, but does not fuse. In closed tube decrepitates, changes color to a light pink. Insoluble in HCl and HNO_3, but soluble in H_2SO_4, with evolution of HF. Occurs in feldspar near Pike's Peak, Colorado. Named after Mr. S. T. Tyson.

The crystals, of which tysonite sometimes forms a central zone, consist for the most part or entirely of *bastnäsite* (App. I., p. 2, also called hamartite by Nordenskiöld), which has arisen from the alteration of the original mineral. Cleavage wanting. H. = 4–4·5. G. = 5·18–5·20. Lustre vitreous to resinous. Color reddish brown. Streak light yellowish gray. An analysis (§) gave: Ce_2O_3 41·04, $(La,Di)_2O_3$ 34·76, CO_2 20·15, F *undet.*

The joint atomic weight of the three metals was determined to be 140·2, calculating part of the oxides to form normal carbonates, the remainder as metals, and estimating the fluorine by difference, the result is obtained:

$(Ce,La,Di)_2O_3$	Ce,La,Di	CO_2	F		
50·13	21·82	20·15	7·90	=	100.

This corresponds closely to the formula: $[R_2]F_6 + 2[R_2]C_3O_9$, which requires: $(Ce,La,Di)_2O_3$ 49·94, Ce,La,Di 21·82, CO_2 20·07, F 8·67 = 100. Compare parisite, Min., p. 702.

Ulexite, Min., p. 598; App. II., p. 57.—Chemical composition discussed, *How*, Chem. News, xxxv., 189, 1877; *Reynolds*, ib., p. 218.

Anal., Tarapaca, Peru, *Raimondi*, Min. Pérou, p. 268, 1878. Prov. Salta, Argentine Repub., *Kyle*, Anal. Soc. Cientif. Arg., x., 169, 1880.

Occurs in Kern Co., Cal., *Blake*, Am. J. Sc., III., xxii., 328, 1881.

See also *Franklandite*, p. 48.

Ullmannite.—Min., p. 73; App. II., p. 57.

Uraninite, Min., p. 154; App. II., p. 57.—Occurrence in Mitchell Co., N. C., *Kerr*, Am. J. Sc., xiv., 496, 1877; *Hidden*, ib., xxii., 22, 1881.

Occurs in small brilliant octahedral crystals, G. = 9·22–9·28, at Branchville, Conn., *Brush* and *E. S. Dana* (Am. J. Sc., III., xvi., 35, 1878); analysis (⅔) by *Comstock* (ib., xix., 220, 1880): U 81·50, Pb 3·97, Fe 0·40, O 13·47, H_2O 0·88 = 100·22. After the determination of the amounts of UO_2 and UO_3, the analysis becomes:

UO_3	UO_2	PbO	FeO	H_2O	
40·08	54·51	4·27	0·49	0·88	= 100·23.

This corresponds to the formula: $3\overset{iv}{R}O_2 + 2\overset{vi}{R}O_3$, with $\overset{iv}{R} = \overset{iv}{U}, Pb_2, Fe_2$, and $\overset{vi}{R} = \overset{vi}{U}$. B.B. the mineral reacts with fluxes for uranium, and on reduction yields a globule of lead. In the closed tube gives off traces of water, which has a slightly acid reaction, the cause of which is not explained.

Uranocircite. *Weisbach*, Jahrb. Berg.-Hüttenwesen, 1877, Abhandl., p. 48.

Orthorhombic; form similar to that of autunite. Cleavage basal highly perfect; macrodiagonal and brachydiagonal distinct. G. = 3·53. Color yellow green. Optically biaxial. Acute bisectrix coincides with *c* (vert.); axial angle = 15°–20°.

Composition: $BaU_2P_2O_{12} + 8aq = P_2O_5$ 14·00, UO_3 56·75, BaO 15·07, H_2O 14·18 = 100. Analysis, Winkler (l. c.):

P_2O_5	UO_3	BaO	H_2O	
15·06	56·86	14·57	13·99	= 100·48.

Earlier analyses by Georgi, and Uwao Imai, gave confirmatory results. Church (Min. Mag., i., 234, 1877) finds, that *in vacuo* over H_2SO_4, at 2o° C., 6aq go off; and the remainder (2aq) at a red heat. Occurs in quartz veins near Falkenstein, Saxon Voigtland. Formerly called autunite (lime-uranite).

Uranophane.—Min., p. 805; App. II., p. 57.

Uranosphærite.—App. II., p. 57.

Uranospinite, App. II., p. 58.—In tabular crystals, combinations of *O*, $\frac{1}{2}$-$\breve{\imath}$, and $\frac{1}{2}$-$\bar{\imath}$, with two undetermined domes. $O \wedge \frac{1}{2}\text{-}\breve{\imath} = O \wedge \frac{1}{2}\text{-}\bar{\imath} = 124° 28'$; *c* (vert.): $\bar{b}:\breve{a}$ = 2·9123 : 1 (approx.): 1. *Weisbach*, Jahrb. Berg. Hüttenwesen, 1877, Abhandl., p. 46 (Z. Kryst., i., 394).

Contains, perhaps, 10aq (not 8aq), according to *Church*, Min. Mag., i., 236, 1877.

Uranothorite.—See *Thorite*, p. 121.

Uranotil, App. I., p. 16; II., p. 58.—Occurs at the "Weisser Hirsch" mine, at Neustädtel, Saxony. In capillary crystals and crystalline groups, also massive, with fine fibrous fracture. G. = 3·814–3·898. Analyses: 1, 2, Winkler:

	SiO_2	UO_3	Fe_2O_3*	CaO	H_2O	
1.	13·02	63·93	3·03	5·13	14·55	= 99·66.
2.	14·48	62·84	2·88	5·49	13·79	= 99·48.

* With tr. aluminum and cobalt oxides.

The formula deduced (that of Boricky) is $Ca[U_2]_3Si_3O_{16} + 9aq$, which requires: SiO_2 14·26, UO_3 68·46, CaO 4·44, HO_2 12·84 = 100. *Weisbach*, J. Min., 1880, ii., 111.

Genth has obtained for uranotil, from Mitchell Co., N. C. (⅔) : SiO_2 13·72, UO_3 66·67, Al_2O_3, Fe_2O_3 tr., PbO 0·60, BaO 0·28, SrO 0·13, CaO 6·67, P_2O_5 0·29, H_2O 12·02 = 100·38, for which he calculates the formula : $Ca_3(UO_2)_6Si_6O_{21}$ + 18aq, requiring : SiO_2 13·95, UO_3 66·98, CaO 6·51, H_2O 12·56 = 100. Amorphous. H. = 2·5. G. = 3·834. Amer. Chem. Journ., i., 88, 1879.

Urvölgyite.—See *Herrengrundite*, p. 57.

Urusite.—See *Sideronatrite*, p. 109.

VAALITE.—App. II., p. 58.

VALENTINITE, Min., p. 184.—On barite from Nagybanya, *Brun*, Z. Kryst., v., 105, 1880.

VALLERIITE.—App. II., p. 58.

VANADINITE, Min., p. 184; App. II., p. 59.—**Cryst.**, Kappel, Carinthia, *v. Zepharovich*, Lotos, 1876 (J. Min., 1876, 561); Kappel, Carinthia, *Vrba*, Z. Kryst., iv., 353, 1880. Cordoba, *Websky*, Ber. Ak. Berlin, 1880, 799, and Z. Kryst., v., 542, 1881.

Analyses, Wanlock-Head, Dumfriesshire, *Frenzel*, Min. Petr. Mitth., iii., 504, 1881. Cordoba, *Rammelsberg*, Ber. Ak. Berlin, 1880, 661. Occurrence at Bölet, Sweden, *Nordenström*, Geol. För. Förh., iv., 209, 1878; anal. Nordström, ib., iv., 267, 1879.

Occurrence in brilliant red crystals at the Hamburg, and other mines in the Silver District, Yuma Co., Arizona, *B. Silliman*, Am. J. Sc., III., xxii., 198, 1881. At the Castle Dome mines, *W. P. Blake*, Min. Sc. Press, Aug. 13 (Am. J. Sc., xxii., 410), 1881.

VANADIOLITE.—App. I., p. 16.

VANADITE.—Min., p. 610; App. II., p. 59.

Vanuxemite. *C. U. Shepard*, Contrib. Min., 1876. A product of the decomposition of zinc ores at Sterling Hill, N. J. Occurs in irregular patches in a firm ochery aggregate. Massive, with an even or conchoidal fracture. Color white ; dull. H. = 2·5–3. G. = 2·5. Does not adhere to the tongue, but emits a slight clayey odor on being breathed upon. An analysis gave : SiO_2 35·64, Al_2O_3 11·70, ZnO 32·48–36·0, H_2O 14·80–19·88. [Obviously a mixture of white clay with hydrous zinc silicate, and hence not a mineral species.]

VARISCITE, Min., p. 582; App. II., p. 59.—The mineral called peganite from Montgomery Co., Ark., is shown by *Chester* (Am. J. Sc., III., xiii., 295; xv., 207) to be identical with the variscite of Breithaupt (Min., p. 582, and Petersen, J. Min., 1871, 357), and also with callainite of Damour (Min., p. 572). Occurs in crusts consisting of minute prismatic crystals, in sheaf-like aggregates; also amorphous. Observed planes: *I*, *i-ī*, *i-ĭ*, *O*; $I \wedge I$ = 114° 6′. H. = 4. Lustre brilliant. Color deep emerald green, bluish green to colorless. Transparent to translucent. B. B. infusible. Analysis (after deducting 70 and 50 p. c. quartz) :

	P_2O_5	Al_2O_3	H_2O	
(⅔)	44·35	31·85	23·80	= 100.

This corresponds to the formula : $Al_2P_2O_8$ + 4aq, or the composition of variscite, according to Petersen (J. Min., 1871, 357).

Anal., *Helmhacker*, Min. Petr. Mitth., ii., 245, 1879.

Vasite.—See *Orthite*, p. 87.

Venasquite.—See *Ottrelite*, p. 87.

Venerite. *T. S. Hunt*, Trans. Amer. Inst. Min. Eng., iv., 825, 1876.

Occurs as a greenish, earthy-looking "clay ore," in irregular layers in the schists connected with the magnetite of Jones mine, near Springfield, Berks Co., Penn. The purer portions have a pea-green, or apple-green color when moist; becomes greenish white on drying, and falls to powder. Under the microscope is seen to consist mostly of minute, shining, transparent scales, with some impurities. Analysis by G. W. Hawes, on material purified by washing, gave: SiO_2 28·93, Al_2O_3 13·81, Fe_2O_3 5·04, FeO 0·27, CuO 16·55, MgO 17·47, H_2O 12·08, insol. 6·22 = 100·87. After deducting the insoluble portion, this becomes: SiO_2 30·78, Al_2O_3 14·67, Fe_2O_3 5·35, FeO 0·29, CuO 17·58, MgO 18·55, H_2O 12·88 = 100. Named in allusion to the alchemistic symbol for copper.

[The substance examined is so evidently wanting in homogeneity, that it cannot be regarded as a mineral species.]

VERMICULITE, Min., p. 498; App. II., p. 59.—Analyses (by Gooch) of varieties from Lerni, Delaware Co., Penn., and Pelham, Mass., and discussion of the relations of this group of minerals, *J. P. Cooke*, Amer. Acad. Sc., x., 453, 1875. Anal., Walney Island, North Lancashire, England, *Parke*, Proc. York. Geol. Pol. Soc., II., iv., 254, 1877.

A related mineral (decomposition product) is called PROTOVERMICULITE by *König* (Proc. Ac. Nat. Sc. Philad., 1877, 269). Micaceous structure. Optic-axial angle small. H. = 2. G. = 2·269. Color yellowish silvery to bronze. Analysis: SiO_2 33·28, Al_2O_3 14·88, Fe_2O_3 6·36, FeO 0·57, MgO 21·52, H_2O (combined) 3·36, H_2O (hygroscopic) 20·54, MnO,TiO_2 tr. = 100·51. König (l. c.) has also analyzed the jefferisite of West Chester, Penn.

Another related mineral, from Philadelphia, is called PHILADELPHITE by *H. C. Lewis* (Proc. Ac. Nat. Sc. Phil., Dec., 1879). Micaceous. H. = 1·5. G. = 2·80. Color brownish red. Inelastic, feel greasy; axial angle, 31°–39°. Analysis (½): SiO_2 35·73, Al_2O_3 15·77, Fe_2O_3 19·46, FeO 2·18, MgO 11·56, CaO 1·46, Na_2O 0·90, K_2O 6·81, H_2O 4·34, TiO_2 1·03, V_2O_3 0·37, MnO 0·50, NiO,CoO 0·06, CuO 0·08, P_2O_5 0·11, Li_2O,Cl,SO_3, etc. tr. = 100·86. Another analysis by Haines gave: 38·79 SiO_2, etc. The mineral is very hygroscopic, and on heating (150°–160°) expands to ten times its volume; a small fragment exfoliating raised 50,000 times its own weight. Lewis makes a series of careful experiments to determine at what temperatures the water is given off. König writes the formula for his mineral $R_3[R_2]Si_3O_{12} + H_2O$, and Lewis for his, $R_4[R_2]_2Si_5O_{20} + 2H_2O$; both are essentially the same as other varieties already described, except in the amount of water present. [As all the minerals of the group are, undoubtedly, decomposition products of other micas, the multiplication of names seems most undesirable.]

Vesbine. A name given by *Scacchi* to the material forming thin yellow crusts on the lava of 1631, Vesuvius, which is supposed to contain a new element called by him vesbium, Att. Accad. Napoli, Dec. 18, 1879.

VESUVIANITE, Min., p. 276; App. II., p. 59.—**Cryst.**, Albani Mts., showing variation in crystallographic constants, *Sella*, Z. Kryst., i., 251, 1877. Ural, *Tarassof*, Verh. Min. Ges. St. Pet., II., xiv., 189, 1879. *Groth* and *Bücking*, Min.-Samml. Strassburg, p. 199, 1878.

Thermo-electric character, *Hankel*, Pogg. Ann., clvii., 162, 1876.

According to *Mallard*, pseudo-tetragonal, and analogous to apophyllite (q. v., also App. III., p. 139), Ann. Min., VII., x., 133, 1876. See also *Brezina*, Min. Mitth., 1877, 98. *Dölter* finds, from a discussion of many measurements, no decisive evidence against the tetragonal character of species, that is, on the morphological side, Z. Kryst., v., 289, 1881.

Anal., Tschammendorf, near Strehlen, Silesia (1·77 p. c. TiO_2), *Schumacher*, J. Min., 1878, 817. Jordansmühl, Silesia (8·2–8·4 p. c. MnO, manganidocrase), *v. Lasaulx*, Z. Kryst., iv., 168, 1879.

VESZELYITE, App. II., p. 59.—*Schrauf*, Z. Kryst., iv., 81, 1879. Triclinic, monoclinic in habit. Incrusting, consisting of a granular aggregate of indistinct crystalline individuals. Occasionally in distinct crystals, combinations of the prisms and brachydomes; $I \wedge I' = 109° \ 15'$, $1\text{-}\breve{\imath} \wedge 1\text{-}\breve{\imath}' = 95° \ 10'$. H. = 3·5–4. G. = 3·531. Color and streak greenish blue. Analysis (on 0·1 gr.):

As_2O_5	P_2O_5	CuO	ZnO	H_2O		
10·41	9·01	37·34	25·20	17·05	=	99·01.

Formula: $2(\text{Zn,Cu})_3\text{As}_2\text{O}_8 + 9(\text{Zn,Cu})\text{H}_2\text{O}_2 + 9\text{aq}$; with Cu : Zn = 3 : 2, and $\text{As}_2\text{O}_5 : \text{P}_2\text{O}_5 = 1 : 1$; this requires: As_2O_5 12·13, P_2O_5 7·48, CuO 37·68, ZnO 25·62, H_2O 17·08 = 100. Closely related in form and composition to libethenite and adamite. Occurs as an incrustation on granite, and on limonite, at Morawitza, in the Banat.

VICTORITE.—App. II., p. 59 (18).

Vietinghofite.—See *Samarskite*, p. 106.

VILLARSITE.—Min., p. 409; App. II., p. 59.

VIRIDITE.—App. II., p. 59.

VIVIANITE, Min., p. 556; App. II., p. 59.—**Anal.**, white variety from Amers, Belgium, *Dewalque*, Ann. Soc. Geol. Belg., iii., 3.

VOLBORTHITE, Min., p. 611.—Woskressenskoi, Perm in the Ural, Genth analyzed the coating on a quartzose rock, finding 85·55 p. c. insol., and 14·45 p. c. soluble, with 4·49 H_2O. The soluble portion yielded: V_2O_5 13·59, CuO 38·01, BaO 4·30, CaO 4·49, H_2O [31·60], SiO_2 1·36, Al_2O_3 4·78, Fe_2O_3 0·45, MgO 1·42 = 100. Neglecting the SiO_2, Al_2O_3, Fe_2O_3, MgO, and a part of the water as impurities, Genth calculates: $(\text{Cu,Ba,Ca})_3\text{V}_2\text{O}_8 + 3\text{CuH}_2\text{O}_2 + 12\text{aq}$, requiring: V_2O_5 19·63, CuO 38·41, BaO 6·17, CaO 6·77, H_2O 29·02. A second analysis gave confirmatory results. Am. Phil. Soc. Philad., xvii., 122, 1877.

VOLTZITE, Min., p. 50.—Joachimsthal, optically uniaxial, positive, *Bertrand*, Bull. Soc. Min., iv., 59, 1881.

Vreckite.—See *Bhreckite*, p. 15.

WACKENRODITE.—App. II., p. 59.

WAD, Min., p. 181; App. II., p. 60.—**Anal.**, Londonderry, N. S., *Louis*, Trans. Nov. Sc. Inst., iv., 427, 1878. New Caledonia (asbolite), *Liversidge*, Proc. Roy. Soc. N. S. W., Sept. 1, 1880.

A mineral near some varieties of wad, from Kamsdorf, Thuringia, is called LEPIDOPHÆITE by *Weisbach* (J. Min., 1880, ii., 109). Structure fine fibrous and scaly. Very soft, soiling the fingers. G. = 2·89–3·04. Lustre silky, dull. Color and streak reddish brown, the latter shining. In closed tube becomes black. Soluble in HCl with evolution of chlorine. Analysis, Jenkins: MnO_2 58·77, MnO 9·59, CuO 11·48, H_2O 21·05 = 100·89, corresponding to $\text{CuMn}_6\text{O}_{12} + 9\text{aq}$, which requires: MnO_2 58·20, MnO 9·50, CuO 10·62, H_2O 21·68.

WAGNERITE, Min., p. 538; App. II., p. 60.—*Bauer* (ZS. G. Ges., xxvii., 230, 1875) suggests that KJERULFINE (App. II., p. 31) is probably identical with wagnerite, but more or less altered; later he shows that the identity is beyond question (J. Min., 1880, ii., 75). Analyses by *Pisani* (Bull. Soc. Min., ii., 43, 1879), *Rammelsberg* (ZS. G. Ges., xxxi., 107, 1879), *Friederici* (J. Min., 1880, ii., 77), agree in general with the wagnerite formula: $\text{Mg}_3\text{P}_2\text{O}_8 + \text{MgF}_2$. The form and optical characters have been studied by *Brögger* and *Reusch* (ZS. G. Ges., xxvii., 675, 1875), and *Brögger* (Z. Kryst., iii., 474, 1879), and a general correspondence with wagnerite finally proved.

Walkerite.—See *Pectolite*, p. 89.

WALPURGITE, App. I., p. 16; II., p. 60.—According to *Weisbach* (J. Min., 1877, 1) the crystals are triclinic, with pseudo-monoclinic symmetry, due to twinning. *Groth* confirms this by an optical examination, Z. Kryst., i., 93, 1877.

WALTHERITE.—See *Bismutite*, p. 15.

Waluewite.—See *Xanthophyllite*, p. 132.

WAPPLERITE, App. II., p. 60.—Cryst. and optical description, *Schrauf*, Z. Kryst., iv., 281, 1880.

WARWICKITE.—Min., p. 600; App. II., p. 60.

Wattevillite. *Singer*, Inaug. Diss. Würzburg, 1879, p. 18.

In very minute acicular crystals, orthorhombic or monoclinic; in part twins; forms fine fibrous aggregates. G. = 1·81. Color snow white. Lustre silky. Taste first sweet, then astringent. Analysis, after deducting 33·69 p. c. hygroscopic water:

SO_3	Al_2O_3	FeO	NiO	CoO	CaO	MgO	K_2O	Na_2O	H_2O		
44·01	0·24	0·88	1·05	1·30	16·87	2·49	4·74	10·46	17·73	=	99·77.

Calculated formula: $RSO_4 + 2aq$, very near polyhalite. B. B. swells up and fuses with difficulty to a white blebby enamel. Very soluble in water; from the concentrated solution, crystals of gypsum separate on standing, and still more quickly on warming. Found on lignite, associated with other related sulphates on the Bauersburg, near Bischofsheim vor dem Rhön, in Bavaria. Named after M. v. Watteville, of Paris.

WAVELLITE.—Min., p. 575; App. II., p. 60.

WERNERITE.—See *Scapolite*, p. 106.

Werthemanite. *Raimondi*, Min. Pérou, p. 244, 1878 (Domeyko, 5th Append. Min. Chili, 1876).

Massive, easily reduced to powder. G. = 2·80. Color white. Gives an argillaceous odor, and adheres to the tongue. Composition: $Al_2SO_6 + 3aq$. Analysis gave: SO_3 34·50, Al_2O_3 45·00, Fe_2O_3 1·25, H_2O 19·25 = 100. B. B. infusible. Soluble in acids. It differs from aluminite only in containing less water. Found in a bed of clay near the city of Chachapoyas, Peru. Pyr. as with aluminite. B. B. infusible; after ignition gives a blue color with cobalt solution. Insol. in HCl, HNO_3 and aqua regia.

WESTANITE.—App. I., p. 16.

WHEELERITE.—App. II., p. 60.

WHEWELLITE.—Min., p. 718; App. II., p. 61.

WHITNEYITE.—Min., p. 37; App. II., p. 61.

WILLCOXITE.—App. II., p. 61.

WILLEMITE.—Min., p. 262; App. II., p. 61.

WINKLERITE.—App. II., p. 61.

WINKWORTHITE.—App. I., p. 17.

WISERINE.—Min., p. 528; App. II., p. 61.—See *Octahedrite*, App. III., p. 85.

WOLLONGONGITE, App. I., p. 17.—See *Torbanite*, p. 123.

WOODWARDITE.—Min., p. 666; App. II., p. 62.

WULFENITE, Min., p. 607; App. II., p. 62.—Occurrence in the silver district, Yuma Co., Arizona; sometimes in simple octahedral crystals, *B. Silliman*, Am. J. Sc., III., xxii. 203, 1881.
Schrauf has given the name CHROMOWULFENITE to some red wulfenite containing chromium, Ber. Ak. Wien, lxiii., 1871.

WURTZITE, Min., p. 59.—**Anal.**, Przibram, *Frenzel*, J. Min., 1875, 678.
Description of artifical crystals, hemimorphic, like greenockite, *Förstner*, Z. Kryst., v., 363, 1881.
See also *Erythrozincite*, p. 43.

XANTHIOSITE.—App. II., p. 62.

Xantholite.—See *Staurolite*, p. 114.

XANTHOPYLLITE, Min., p. 508.—A variety is called WALUEWITE by v. Kokscharof (*P. v. Jeremejef*, Verh. Min. Ges. St. Petersburg, II., xi., 341, 355, 1876; *N. von Kokscharof*, Z. Kryst., ii, 51, 1877 (Min. Russl., vii., 346)).
Monoclinic in symmetry. Axes, $c : b : \grave{a} = 3{\cdot}2728 : 1 : 0{\cdot}5768$. $\beta = 90° \; 0'$. Observed planes: O, $-\frac{1}{2}\text{-}i$, $\frac{1}{4}\text{-}i$, $i\text{-}\grave{3}$, $\frac{1}{3}$, $-\frac{1}{3}$, $\frac{3}{4}\text{-}\grave{3}$; $O \wedge -\frac{1}{2}\text{-}i = 109° \; 28'$; $O \wedge \frac{3}{4}\text{-}\grave{3} = 109° \; 28'$; $-\frac{1}{2}\text{-}i \wedge \frac{3}{4}\text{-}\grave{3} = 109° \; 28\frac{1}{2}'$: $O \wedge \frac{1}{4}\text{-}i = O \wedge -\frac{1}{3} = -\frac{1}{3} \wedge \frac{3}{4}\text{-}\grave{3} = -\frac{1}{3} \wedge i - \frac{1}{2}\text{-}i = 140° \; 46'$; these angles correspond closely with the isometric system. Plane angle of the base 120°. Twins common, similar to those of mica; twinning-plane *I*. Cleavage: basal perfect. H. = 4·5. G. = 3·093. Lustre vitreous; on cleavage plane pearly. Color leek to bottle-green. Transparent to translucent. Strongly dichroic, parallel *c* (vert.) fine green, perpendicular to *c* (vert.) reddish brown. Optical properties (H. Bücking): axial plane the clinodiagonal section; bisectrix negative, inclined 32° to the normal (probable error not greater than 1$\frac{1}{2}$°). Axial angle about 20½° (20°–40° Des Cloizeaux, $\rho < \upsilon$). Analysis, P. v. Nikolajef:

SiO_2	Al_2O_3	Fe_2O_3	FeO	MgO	CaO	H_2O	
16·90	43·55	2·31	0·33	17·47	13·00	5·07	= 98·63.

Found with perofskite and other species in chloritic schists in the mine Nikolaje-Maximilianowsk, near Achmatowsk, in the southern Ural. Named after the Russian Minister, P. A. von Waluew.
See also *Clintonite*, p. 28.

XENOTIME, Min., p. 528; App. II., p. 62.—**Cryst.**, Binnenthal, *Klein*, J. Min., 1875, 369; St. Gothard, ib., 1879, 536.
Occurrence at Königshayn, Görlitz, Silesia, *v. Lasaulx*, J. Min., 1877, 174. Crystals compounded with zircon from Alexander Co., N. C., *W. E. Hidden*, Am. J. Sc., III., xxi., 244, 1881.
Anal., Hitteröe, *Schiötz*, J. Min., 1876, 306.

Youngite. *Hannay*, Min. Mag., i., 152, 1877; ii., 88, 1878.
A coarsely crystalline, apparently homogeneous mineral. H. = 6. Lustre metallic, resembling fractured cast-iron. A specimen of unknown source yielded Hannay, analyses 1,

2, 3, 4; and a specimen from Ballarat, Australia, gave Stewart and Hood, analyses 5 and 6 (mean of several):

	S	Pb	Zn	Fe	Mn	
1. G. = 3·62	28·85	20·92	40·07	....	11·13	= 100·97.
2. G. = 3·59	27·50	24·22	38·46	2·83	6·93	= 99·94.
3.	26·93	24·58	37·92	2·80	6·77	= 99·00.
4.	28·99	22·18	37·75	3·14	7·00	= 99·06.
5.	27·43	26·02	35·42	9·16	1·28, Sb 0·25, SiO_2 0·18	= 99·69.
6. G. = 4·56	27·28	25·73	36·62	8·73	1·30, SiO_2 0·10	= 99·76.

Corresponds approximately to a simple sulphide containing lead and zinc, with varying quantities of iron and manganese. Named after Mr. John Young, of Glasgow.

[The description of "Youngite" is very incomplete (note the disparity in the determinations of the specific gravity), and the composition is improbable. Analyses 1 and 2, for which separate formulas are given by the author, were obtained from the same specimen! Beyond question a mechanical mixture.]

YTTROCERITE.—Min., p. 625; App. I., p. 62.

Yttrogummite.—See *Cleveite*, p. 27.

YTTROTANTALITE.—Min., p. 519; App. II., p. 62.

ZARATITE, Min., p. 710.—From the mines of Rapi, Province de la Mar, Peru, *Raimondi*, Min. Pérou, p. 206, 1878.

ZEPHAROVICHITE.—App. I., p. 62.

ZEUNERITE, App. II., p. 62.—Cryst., and association with uranospinite, *Weisbach*, Jahrb. Berg.-Hütt., 1877, Abhandl., p. 45 (Z. Kryst., i., 394).

ZINC, Min., p. 17.—Reported as found in the native state in north-eastern Alabama, *W. D. Marks*, Am. J. Sc. III., xi., 234, 1876.

Zincaluminite. *Bertrand* and *Damour*, Bull. Soc. Min., iv., 135, 136, 1881.

In minute crystals, forming very thin hexagonal plates. Optically uniaxial, negative, and hence hexagonal, or possibly orthorhombic with $I \wedge I = 120°$ nearly (Bertrand). H. = 2·5–3. G. = 2·26. Color white, or slightly bluish. Analysis, Damour, deducting a little clay associated with it:

SO_3	Al_2O_3	ZnO	CuO	H_2O	
12·94	25·48	34·69	1·85	25·04	= 100.

Formula: $2ZnSO_4 + 4ZnH_2O_2 + 3Al_2H_6O_6 + 5aq$, requiring: SO_3 12·48, Al_2O_3 24·12, ZnO 38·12, H_2O 25·28 = 100. B. B. in the closed tube gives off abundance of water. Slightly alkaline. With cobalt solution on strong ignition, gives a greenish-gray mass with blue at some points. On charcoal a zinc coating. Soluble in HNO_3, leaving 5 to 7 p. c. clay. From the zinc mines of Laurium, Greece.

ZINCITE.—Min., p. 135; App. II., p. 63.

ZINKENITE, Min., p. 88.—Anal., *Sendtner*, from Adlersbach, near Hausach, Kinzigthal, Ann. Ch. Pharm., clxxxv., 205, 1877.

ZINNWALDITE.—See *Mica Group*, p. 77.

Zircarbite. *C. U. Shepard*, Contrib. Min., 1877. A massive, compact, or cellular, yellowish-brown, opaque mineral. H. = 2–2·5. B. B. infusible. Chemical nature unknown. With cyrtolite, at the granite quarries of Rockport, Mass.

ZIRCON, Min., p. 272; App. II., p. 63.—Supposed to occur in microscopic twin crysta *Meyer*, ZS. G. Ges., xxx., 11, 352, 1878; *Stapff*, l. c., xxx., 133; xxxi., 405, 1879; *Rie* Min. Petr. Mitth., i., 203, 1878; *Hussak*, Min. Petr. Mitth., i., 277, 1878; this conclusi questioned by *Sauer*, J. Min., 1879, 569; *Rosenbusch*, Att. Accad. Torino, June 19, 1881.

Large twin crystal (1-*i* as twinning-plane), from Renfrew, Canada, *W. E. Hidden*, An J. Sc., III., xxi., 507, 1881; same observed by *L. Fletcher*, Z. Kryst., vi., 80, 1881. Th crystals from Renfrew occur with gigantic titanite crystals (p. 122), and are sometim very large. From various Italian localities, *Uzielli*, Accad. Linc. Mem., II., iii., 1876.

Mallard (Ann. Min., VII., x., 143, 1876) includes zircon among the pseudo-tetragona minerals.

Specific gravity determination, *Church*, Geol. Mag., II., ii., 322, 1875.

Anal., El Paso, Colorado, *König*, Am. Phil. Soc. Phil., xvi., 518, 1877, or Z. Kryst., i., 432.

Color due to state of oxidation of iron, and varied in R. F. and O. F., *Spezia*, Att. Ac Torino, xii., 37, 1876.

A variety of zircon from Ceylon is called BECCARITE by *Grattarola* (Att. Soc. Tosc., iv., 177, 1879). Color olive green. Optically biaxial, with apparently twinned structure; a basal section is divided into four sectors in polarized light. Form and other characters like zircon. Analysis: SiO_2 30·30, ZrO_2 62·16, Al_2O_3 2·52, CaO 3·62, ign. 0·30 = 98·92. Named for Dr. O. Beccari.

See also *Cyrtolite*, p. 33.

ZIRLITE.—App. II., p. 63.

ZÖBLITZITE, App. II., p. 34.—**Anal.** (a white serpentine), *Frenzel*, J. Min., 1875, 680.

ZOISITE, Min., p. 290; App. II., p. 63.—**Anal.**, Syra, *Lüdecke*, ZS. G. Ges., xxviii., 258, 1876. Leiperville, Delaware Co., Pa., *König*, Proc. Ac. Nat. Sc. Philad., 1878, 83.

Cryst. (thoulite), Souland, Norway, *Brögger*, Z. Kryst., iii., 471, 1879.

Crystallographically and chemically investigated by *Tschermak* and *Sipöcz* (Ber Ak. Wien, lxxxii., 141, 1880). The measurements (of crystals from Ducktown, Tenn., by Becke) confirm the accepted orthorhombic character. The optical characters are peculiar, in consequence of the presence of twin lamellæ. An analysis of transparent crystals from Ducktown, by Ludwig, gave: SiO_2 39·61, Al_2O_3 32·89, Fe_2O_3 0·91, Fe 0·71, MgO 0·14, CaO 24·50, H_2O 2·12 = 100 88. This corresponds to the already accepted formula: $H_2Ca_4[Al_2]_3Si_6O_{26}$, analogous to that epidote, in which $[Fe_2]$ takes the place of $[Al_2]$; between the two various intermediate compounds exist, according to the extent to which the iron and aluminum respectively replace each other.

ZONOCHLORITE.—See *Prehnite*, p. 96.

ZORGITE, Min., p. 48.—Analyses of related minerals $(Pb,Cu)Se$, and $(Cu,Pb)_3Se_2$, from the Andes, *Pisani*, C. R., lxxx., 391, 1879.
